General Larval Types.—Although marine annelids and mollusks differ greatly in their basic adult morphology, they produce so-called trochophore larvae that are almost identical. Larvae very similar in their basic structure to the trochophore larva also develop in other phyla among the Protostomia. Similarly, although echinoderms and hemichordates differ so very strikingly in their adult morphology, their embryonic development results in a larval stage that is almost identical in the two phyla; this larva has been called the dipleurula. Consequently it is often stated that another way in which the Deuterostomia differ from the Protostomia is their ability to form a dipleurula larva, which is distinctly different from the trochophore. Because of the phylogenetic significance attached to these two larval types, some attention should be paid to their basic structure.

Trochophore.—The trochophore larva (fig. 2[E]) is somewhat biconical in shape. Around the equator there is a ciliated swimming structure termed the prototroch; other ciliated bands may be present as well. At the apical pole is a sensory apical plate

bearing a tuft of enlarged cilia; various other sensory structures may be present also. A ciliated digestive tract leads from the mouth at the equator through the elongated stomodaeum and enlarged stomach to the narrow intestine and finally to the anus at the lower pole. The prominent blastocoel is more or less occupied by mesenchyme cells and well-developed larval muscle cells, all formed from ectomesoderm. Within the loop formed by the digestive tube are the paired mesodermal bands. Near each of these is a nephridium (excretory structure) consisting of a tubule whose inner end is closed by one or more solenocytes or flame cells (a long tubular cell having a flagellum moving in the tube).

Dipleurula.—In contrast to the trochophore larva, the dipleurula larva (fig. 2[F]) is actually a hypothetical organism combining the features common to all echinoderm and hemichordate larvae. It is bilaterally symmetrical and in different groups gives rise to more advanced variant forms such as the pluteus, bipinnaria, brachiolaria and other larval types. The locomotor organ is a ciliated band surrounding the mouth and is thrown into preoral and anal loops. The ciliated digestive tube possesses the same subdivisions as that of the trochophore larva. No derivatives of ectomesodermal origin are present in the blastocoel. Instead, the latter is occupied by the paired enterocoelic coeloms, each of which is partially divided into anterior, middle and posterior portions. The left coelom, and sometimes the right as well, establishes a connection to the outside by way of the stone canal and madreporic pore. No nephridium of any kind is present.

Thus the two general larval types, the trochophore and the dipleurula, are so different in certain basic features that they would seem to be as reliable indicators of two different lines of evolution as those aspects of embryonic development used to distinguish the Protostomia from the Deuterostomia. *See* also ANIMALS, PHYLOGENY OF.

SURVEY OF PHYLA

As mentioned in the opening paragraph the Protozoa are excluded from this discussion. Among the metazoans only the Mesozoa are excluded; the Parazoa, comprising only the phylum Porifera, or the sponges, and the Eumetazoa, including Radiata and Bilateria, contain all the remaining phyla.

PARAZOA

Porifera.—Embryonic development of sponges differs so markedly from that of all true Metazoa that we can only conclude that the phylum Porifera diverged from the evolutionary lines of higher organisms at a very early stage in metazoan evolution. The peculiar feature of embryonic development of calcareous and siliceous, or horny, sponges is the fact that the cells of the animal hemisphere appear to form structures typically formed by the vegetal hemisphere of other Metazoa, and vice versa. Thus the cells of the animal hemisphere become flagellated and eventually line the internal cavity (spongocoel) as a layer of collar cells (choanocytes), whereas the cells of the vegetal hemisphere eventually form the outer epidermal covering and ectomesenchyme. The future choanocytes of calcareous sponges at first develop flagella at their inner ends facing the blastocoel. A mouth forms within the group of nonflagellated cells, and the blastula turns itself inside out to form the characteristic larval type of this group, the amphiblastula (fig. 2[G]). Embolic gastrulation then occurs, bringing the future choanocytes inside the future epidermal cells (fig. 2[H]). In other sponges flagella arise on the outside of all cells of the blastula except the most posterior (vegetal) ones. The latter wander into the interior, resulting in formation of a stereogastrula. Later the internal cells migrate to the surface, thus enclosing the flagellated cells that develop into choanocytes.

EUMETAZOA

Two phyla among the remaining Metazoa are characterized by radial symmetry and are hence spoken of collectively as the Radiata, namely the Coelenterata and the Ctenophora. All other metazoan phyla are characterized by bilateral symmetry. For this reason the Radiata, as well as the Porifera, are considered to be offshoots of the main evolutionary line leading to the Bilateria or to be descendants of different protozoan ancestors.

Coelenterata.—The phylum Coelenterata contains the hydroids, jellyfishes, sea anemones and corals. These animals exhibit two basic morphological patterns, the polyp and the medusa. Only the medusoid form is capable of sexual reproduction, except in those species that lack a medusa, in which case the polypoid form can reproduce sexually. Cleavage is typically indeterminate, holoblastic and either radial or irregular. The blastomeres often adhere loosely to one another. The capacity for complete regulation is retained by portions of coelenterate eggs until surprisingly advanced cleavage and blastula stages. Endoderm formation typically involves unipolar or multipolar ingression or delamination, resulting in formation of a stereogastrula that soon develops into the characteristic planula larva (fig. 2[I]). However, in certain more complex coelenterates cleavage may result in formation of a coeloblastula, which then undergoes gastrulation by invagination. The planula typically attaches by its blunt anterior end; the endoderm rearranges itself into an epithelium bounding a gastrovascular cavity, a mouth breaks through at the free end, tentacles arise around the mouth and stolons around the base, thus resulting in formation of a typical polyp. Budding (an asexual method of reproduction) results in formation of other polyps (in colonial forms) or of medusae. Thus in coelenterates that possess a medusoid form there is said to take place an alternation of generations: embryonic development of the egg produces a planula larva that develops into a polyp, which produces medusae by asexual methods; the medusa, in turn, reproduces sexually by means of eggs and sperm. An asexual generation (the polyp) alternates with a sexual generation (the medusa). In the case of jellyfish the polyp is called a scyphistoma. By transverse fission (strobilation) it buds off miniature jellyfishes called ephyrae larvae, which in turn develop into adult jellyfishes. In some coelenterates the planula larva develops into an unattached polypoid form called the actinula larva, which then becomes attached to complete its development into a polyp.

Ctenophora.—Development of the ctenophores (comb jellies) differs markedly from development of the coelenterates. Cleavage is typically determinate, holoblastic and biradial (disymmetric). The basic feature of this cleavage pattern is evident at the eight-cell stage (fig. 1[D]). The eight blastomeres are arranged in two rows of four each, with the central cells larger than the end ones. There are two planes that can divide the egg into halves that are mirror images of one another. These eight cells produce two generations of micromeres that overgrow the macromeres to form the entire epidermis including the eight rows of swimming plates characteristic of ctenophores. Thus gastrulation is mainly by epiboly, although the macromeres invaginate somewhat into the interior so that the gastrula arises by the combined processes of epiboly and emboly. Although the exact origin of the mesoderm is not certain, it is believed to be ectomesoderm, as in some of the coelenterates. A planula larva is not formed. Suitable experiments have demonstrated that the fates of the blastomeres, at least of certain of the micromeres, are as rigidly determined at an early stage as are the fates of the micromeres in eggs that undergo spiral cleavage.

Echinodermata.—Among the Bilateria, attention will be directed first to the Deuterostomia and to the embryonic development of representatives of the phylum Echinodermata. Development is best known in the case of eggs of sea urchins and sand dollars (class Echinoidea). Cleavage progresses rapidly and is of the holoblastic equal type until the eight-cell stage (fig. 3[C]), whereupon each of the four vegetal cells gives rise to a small micromere at the vegetal pole (fig. 3[D]). Subsequent cleavages lead to formation of four tiers of cells above the micromeres (fig. 3[E, F]), referred to in order from the animal to the vegetal poles as an_1, an_2, veg_1 and veg_2.

The structures contributed to the resulting larva by derivatives of each tier of cells can be determined readily by examining fig. 3(G–N). A typical coeloblastula is formed (fig. 3[G, H]) and gastrulation occurs by classical embolic invagination of the veg_2 cells to form the archenteron (fig. 3[J]). Paired coelomic pouches arise from the blind end of the archenteron (fig. 2[C]), and sub-

sequently constrict free from the archenteron. Later these each constrict partially into three antero-posterior subdivisions (fig. 2[F]). Thus the endomesoderm and coelom form by the enterocoelous method. A stomodaeum arises from the ventral ectoderm (fig. 3[K]) and establishes connection with the blind end of the archenteron, which subsequently differentiates into esophagus, stomach and intestine. The original blastopore persists as the larval anus. A ciliated band develops around the ventral surface (fig. 3[L], left). Projections arise and form various larval arms. The ciliated band extends along these arms. The resulting larva (fig. 3[M, N]) is the pluteus larva. Development of certain brittle stars (class Ophiuroidea) likewise results in formation of a pluteus larva, in this case called ophiopluteus.

S. Hörstadius has been able to separate the individual tiers of cells and to recombine them at will. By such delicate operations he has been able to demonstrate that normal development depends upon the proper balance between certain forces concentrated in the animal half (animalizing tendencies) and other forces concentrated in the vegetal half (vegetalizing tendencies). For example, an isolated animal half will not develop normally, and neither will an isolated vegetal half. But if the an_1 and an_2 tiers are combined with micromeres, thereby balancing strong animalizing against strong vegetalizing tendencies, a normal larva results. Current research is seeking to find a chemical or physical basis for these animalizing and vegetalizing influences, and considerable progress has been made.

Development of starfish (class Asteroidea) likewise involves total and approximately equal cleavage. Micromeres do not form and the tiers of cells characteristic of sea urchins are not distinguishable. Gastrulation, formation of the digestive tract and coelom formation occur essentially as in sea urchins. Similarly the previously uniform ciliation becomes concentrated into the usual locomotor band. The larva rapidly puts out projections bordered by the ciliated band; these correspond to the arms of echinoid larvae. The larva is then called a bipinnaria (fig. 4[A]). It typically transforms later into a brachiolaria larva (fig. 4[B]), characterized by the possession of three additional brachiolar arms. Some asteroids develop more directly by omitting one or more larval stages. Development of sea cucumbers (class Holothuroidea) is essentially the same, but the resulting larva is called the auricularia. It may transform into another larva called the doliolaria, or the latter may arise directly from the egg without formation of an auricularia stage. Crinoids or sea lilies similarly develop a doliolaria larva. In all classes the bilaterality of the larval stages bears witness to the origin of the echinoderms from bilateral ancestors. Metamorphosis of echinoderms typically involves the loss of bilateral symmetry and the secondary formation of a derived radial symmetry. The metamorphic events are extremely complex, especially as regards the history of the subdivisions of the coelom.

FIG. 3.—DEVELOPMENTAL SEQUENCE OF SEA URCHIN EGG LEADING TO FORMATION OF PLUTEUS LARVA. THE KEY TO THE PRESUMPTIVE GERM LAYERS IS INDICATED AT F; *see* TEXT

Hemichordata.—Members of the wormlike phylum Hemichordata (sometimes considered a subphylum of Chordata) differ so completely from adult echinoderms that there is no obvious relationship between them on the basis of comparative anatomy. And yet, when the details of their embryonic development and larval structure are compared, the conclusion seems inescapable that hemichordates and echinoderms stem from a common ancestor. Cleavage is holoblastic, approximately equal and mostly of the radial type. Formation of a coeloblastula is followed by gastrulation by embolic invagination. The blastopore, which marks the posterior end, is the site of the future anus. The inner end of the archenteron is cut off as a coelomic vesicle that establishes continuity with the outside by a pore located on the left side. Development of the digestive tract is strikingly similar to that of echinoderm larvae. A distinct ciliated swimming band forms in much the same way as in the asteroid bipinnaria larva. The resulting larva is called the tornaria (fig. 4[C]), and was originally mistaken for an asteroid larva. There appears to be little doubt that the hemichordates stand close to the evolutionary line leading to the cephalochordates and urochordates; *i.e.*, to the invertebrate members of the phylum Chordata.

Pogonophora.—The Pogonophora, considered a phylum by some, appears to be closely related to the Hemichordata on anatomical grounds. Cleavage and blastulation differ markedly from these processes in other deuterostomes, but coelom formation is by the enterocoelous method.

Chaetognatha.—Although comparative anatomy suggests that the phylum Chaetognatha is closely related to the phylum Aschelminthes, the embryology of chaetognaths suggests an affinity with other members of the Deuterostomia. Cleavage is of the equal holoblastic type, is radial and indeterminate. A spherical blastula forms and undergoes typical embolic gastrulation. The blastopore marks the future posterior end and the site of the future anus. Paired coelomic pouches arise from the archenteron by an enterocoelous method that differs in detail from the method encountered in echinoderms. A ciliated larval stage is lacking, the animal hatching as a small replica of the adult.

Platyhelminthes.—The first phylum among the Protostomia to receive attention here is that containing the flatworms, Platyhelminthes. All members of two classes of this phylum are exclusively parasitic; *i.e.*, the trematodes or flukes and the cestodes or tapeworms. The structure and life histories of these parasites are highly modified for the parasitic way of life. Moreover, the embryonic development of the majority of the free-living flatworms (class Turbellaria) is likewise greatly modified by the fact that the yolk is not present in the eggs themselves, as in most other phyla, but is contained within special yolk cells that nourish the developing embryos. Only the Acoela and the Polycladida in this class lack these yolk cells, and their development alone appears to be relatively unmodified from its original pattern. Cleavage in the eggs of polyclads is holoblastic and spirally determinate. The cleavage pattern and cell lineage are strikingly similar to those of annelids and mollusks, indicating the phylogenetic relationship of the polyclads to these phyla. Gastrulation occurs chiefly by epiboly, resulting in formation of a stereogastrula. Ectomesoderm arises from cells of the second and possibly the third quartet of micromeres. One cell of the fourth quartet (4d) provides all of the endomesoderm as well as the en-

tire endoderm. The gastrula stage may develop directly into a small worm, which then escapes from the egg capsule, or it may develop into a larval form known as Müller's larva, whose chief characteristic is the development of eight posteriorly directed lobes or lappets (fig. 4[D]); these lobes disappear as the larva develops into a small worm. In some species the larva has only four lobes and is called Götte's larva. Development of the eggs of Acoela is interesting in that they undergo only one meridional cleavage instead of the usual two; accordingly, these two cells produce successive duets of micromeres rather than the usual quartets. Moreover, there is no separation of the interior cells of the stereogastrula into endoderm and endomesoderm, and no digestive cavity forms.

Nemertina.—The nemertine worms (phylum Nemertina) are grouped with the flatworms as the acoelomate Bilateria, *i.e.*, the bilateral animals without a coelom; there seems to be little doubt that nemertines are derived from the flatworms. Cleavage follows the spiral determinate pattern. There are four quartets of so-called micromeres, although they are actually larger than the so-called macromeres. A ciliated coeloblastula usually results. Gastrulation is typically by epiboly, sometimes by invagination of macromeres, occasionally by unipolar ingression. Ectomesoderm forms from micromeres, probably most commonly from the second quartet, and endomesoderm arises from teloblast cells that usually arise from the 4d cell. There is no definite formation of mesodermal bands from teloblasts. Although spaces sometimes appear within the endomesoderm, they are not sufficiently constant or definite to warrant the designation of coelom. Development is often direct but in some cases leads to formation of a pilidium larva (fig. 4[E]) or of Desor's larva, which is a pilidium modified for creeping. The pilidium is provided with an apical sense organ, atop of which is a long spike of cilia. Except for this tuft and the marginal locomotor cilia called the prototroch, the cilia are of uniform size and distribution. The two lobes that hang from the sides suggest the corresponding ones of Müller's larva. The gut cavity opens by a wide blastopore and curves posteriorly to form the stomach. This larva appears to be a preliminary step in the direction of formation of a trochophore larva. Eggs of one of the nemertine worms, *Cerebratulus*, have been used extensively for classical experiments on mechanisms of differentiation. From at least the eight-cell stage on, development appears to be clearly of the determinate type, since experiments provide no evidence of cellular interaction at these stages. However, isolation of animal and vegetal halves of the egg prior to fertilization, as well as other experiments, demonstrate that any fragment of the unfertilized egg can develop into a normal pilidium larva, indicating a high degree of regulative capacity in early stages. Certain other experiments demonstrate that the change from a regulative to a determinate type of development occurs progressively during the period extending from the time of dissolution of the germinal vesicle (egg nucleus) to the time of fusion of the egg and sperm pronuclei; *i.e.*, in stages immediately prior to the first cleavage.

Aschelminthes, Acanthocephala and Entoprocta.—Three phyla are spoken of as the pseudocoelomates, namely the Aschelminthes, Acanthocephala and Entoprocta. In these groups the body cavity that appears superficially to be a coelom actually proves to be a persisting blastocoel. The phylum Aschelminthes contains the Rotifera, Gastrotricha, Kinorhyncha, Priapulida, Nematoda and Nematomorpha. In general the embryology of these forms is incompletely known and, where known, provides few clues concerning relationships with other phyla. However, there is some indication that this group is closely related to flatworms and may be derived from some primitive turbellarian.

Development has been studied in detail only in the nematodes. They exhibit rigid mosaic development, but the most interesting feature of their development is the early segregation of a germ-cell line from a somatic-cell line. During cleavage stages chromosomes remain intact only in cells of the germ-cell line; in cells of the somatic-cell line they undergo a process of "chromatin diminution," surviving in a broken and reduced state.

Cleavage in the phylum Acanthocephala seems to be of the spiral type, thus relating the group to other Protostomia, and the embryology presents a number of points of resemblance with that of the Platyhelminthes. However, embryonic development of this phylum presents so many peculiarities that it has been of little value in establishing phylogenetic relationships. Cleavage in the phylum Entoprocta is spiral and determinate in its broad aspects, although the details differ in marked ways when compared with the development of other Protostomia.

Annelida, Mollusca and Others.—In spite of marked differences in adult anatomy, development of certain marine members of the phyla Annelida and Mollusca, and of the phyla Sipunculida and Echiurida, is so similar up to the trochophore stage that these groups can be considered together. Among classical papers written by American embryologists are those of E. B. Wilson on cleavage pattern and cell lineage of the marine worm *Nereis*, and of E. G. Conklin on cleavage pattern and cell lineage of the marine mollusk *Crepidula*. There are striking similarities of development in these two distinct phyla even down to the most minute details.

Cleavage is clearly of the spiral, determinate type. Four quartets of micromeres are formed (fig. 2[A]), with the ectomesoderm being produced by the second quartet and the endomesoderm from the 4d cell by way of teloblast cells that in turn proliferate the two mesodermal bands (fig. 2[D]). The coelom forms within these bands by a schizocoelous method. In annelids the mesodermal bands become segmented and their primary segmentation is imposed upon the rest of the body, whereas in mollusks such segmentation is lacking. Gastrulation is typically by epiboly and results in formation of the classical type of trochophore larva. The trochophore of annelids metamorphoses directly into the adult form, whereas the trochophore of mollusks often assumes another larval form, the veliger, before metamorphosing into the adult. This larva is characterized by a great overdevelopment of the swimming structure, the prototroch, to form the velum. The original bilateral symmetry of the molluscan larva is secondarily lost during the complex metamorphosis.

Many classical experiments have been made on the eggs of marine annelids and mollusks that establish beyond doubt that development is of the rigidly determinate type once cleavage gets under way. However, if some of these eggs are treated appropriately prior to the first cleavage, each of the first two blastomeres can, if isolated, develop into a normal larva. Thus, as in the case

of the nemertine worm *Cerebratulus*, development of the egg is regulative in its earliest stages, becoming determinate by the time the first cleavage is completed.

Phoronida, Ectoprocta and Brachiopoda.—Three other metazoan phyla are spoken of collectively as the lophophorate coelomates, namely the Phoronida, Ectoprocta (Bryozoa) and Brachiopoda. Certain aspects of their embryonic development suggest close affinities with the Protostomia; among them are the following: (1) traces of spiral cleavage in phoronids; (2) gastrulation commonly by epiboly (phoronids and brachiopods); (3) formation of the mouth from the blastopore region; (4) trochophorelike larvae with apical organ (actinotroch of phoronids, cyphonautes of ectoprocts); (5) solenocytic protonephridia (phoronids); and (6) swimming organ a ciliated band near or below the equatorial plane (phoronids, ectoprocts). But in their type of cleavage (often radial or irregular) and in the type of blastula they form (coeloblastula), they resemble the Deuterostomia. Moreover, some brachiopods appear to form the coelom by an enterocoelous method as in the Deuterostomia. Thus the lophophorate coelomates seem to constitute somewhat of a connecting link between Protostomia and Deutèrostomia, although in general they seem to be more closely related to the former.

Arthropoda.—The major phylum remaining for consideration is the Arthropoda. On the basis of comparative anatomy there appears to be little doubt that this phylum originated from the Annelida. Nevertheless, most arthropods differ strikingly from members of all other phyla both in their embryonic development and in their larval types. Their eggs are typically of the centrolecithal type and characteristically undergo superficial cleavage, thus producing a periblastula, which consists of a layer of blastomeres (the blastoderm) enclosing a central mass of yolk (fig. 5[A]). The blastoderm soon thickens ventrally to form the ventral plate or germ band. Endoderm forms from this ventral plate by invagination from a localized area or from a less restricted area, but sometimes it originates in more obscure ways involving immigration and delamination. In general, the endoderm appears to form the mid-gut. The fore-gut arises from the ectodermal stomodaeum and the hind-gut from the ectodermal proctodaeum. The three subdivisions of the digestive tract eventually become confluent. A mass of mesoderm also forms from the ventral plate, usually in close relation with the endoderm, sometimes seemingly proliferated by the latter. It frequently extends anteriorly as two distinct mesodermal bands (so-called derived mesodermal bands). These typically divide into segments or somites within each of which a coelomic cavity appears (schizocoelous method). Fusion of these separate coelomic cavities soon follows, but coelom development in arthropods remains rudimentary. Paired rudiments of appendages begin to take form on the ventral plate and distinct body segments become evident externally (figs. 5[B]–6[B]). In the cases of insects and arachnids the developing embryo encloses itself in two protective embryonic membranes, the amnion and serosa (fig. 5[D]). Arthropod eggs are not very satisfactory for experimental purposes; therefore, with the exception of insect eggs, not much is known about the physiology of their development.

Crustaceans hatch in a variety of larval forms. The most typical crustacean larva is the nauplius (fig. 4[F]), a minute creature, egg shaped, broad anteriorly, provided with three pairs of appendages—antennules, antennae and mandibles—and a single median eye. This level of development may be passed over as an embryonic stage (fig. 6[A]), the animal hatching in a more advanced stage of development such as a metanauplius (fig. 4[G]), a protozoea (fig. 4[H]) or a zoea (fig. 4[I]). Lobsters hatch in a still more advanced stage known as the megalops (fig. 4[J]). Crustaceans that hatch in a simpler larval form (such as the nauplius) may transform into one or more other larval forms in this series before metamorphosing into the adult body form. Each new larval form emerges only after molting or shedding the exoskeleton. In several instances it has been possible to recognize certain adult animals as crustaceans only when it was discovered that their eggs hatched into a nauplius larva. This is true of the barnacles, which superficially appear to be mollusks, and of some parasitic crustaceans such as *Sacculina*, which in the adult stage is extremely modified in adaptation to its special way of life, being reduced to a tumourlike sac.

FIG. 6.—DEVELOPMENT OF CRAYFISH EGG: (A) VENTRAL VIEW OF VENTRAL PLATE SHOWING RUDIMENTS OF APPENDAGES; (B) SAME VIEW SHOWING FURTHER DEVELOPMENT

Some insects hatch in a form essentially like that of the adult. These are known as ametabolous insects. Most insects, however, hatch in a larval form differing from the adult in lesser or greater degree. If the segments and appendages of the larva later become directly converted into those of the adult, the insect is said to be heterometabolous (or hemimetabolous) and the larval stages are spoken of as nymphs. A heterometabolous insect is said to undergo incomplete metamorphosis. In striking contrast is the holometabolous insect, which hatches as a larva completely different from the adult in external form, nature of appendages and internal organization. Such a larva is usually active and very voracious. It subsequently enters a quiescent or pupal stage during which a more or less complete reconstruction of the organs takes place. Many larval tissues are broken down by phagocytic or other action. New adult structures are built up from certain patches of cells present in the larva as the imaginal discs. Thus a holometabolous insect is characterized by complete metamorphosis.

INVESTIGATION, CRIMINAL. The principal purpose of criminal investigation is to provide answers to certain questions relating to crime. These include: the identity of the victim; the exact place at which the offense occurred; how the crime was committed and the means employed in its commission; the time of attack; the motive or object of attack; and the identity of the offender or offenders. Criminal investigation is employed also in the search for and interrogation of material witnesses who are able and willing to give competent and relevant testimony against the suspect or offender, and in the reconstruction of all facts connected with the crime in order that, at the trial of a defendant, a true picture of what occurred may be presented so as to leave no doubt in the minds of the jurors or judge regarding the guilt or innocence of the accused.

HISTORY

Although the beginning of criminal investigation is unknown, there is reason to believe that it came into existence in a very

rudimentary form with the origin of legal trials. It is clearly laid down in the code of Hammurabi (*c.* 18th century B.C.) that suspicion does not give ground for condemnation; receiving of testimony and even elaborate examination of sites or circumstances by the court itself were established rules of procedure.

In Athens, by about 500 B.C., the examination of facts had become meticulous; a defendant, having lost his case, might bring suit against a witness for bearing false testimony and, if successful, would be freed of his earlier condemnation. In the Justinian legislation (6th century A.D.) evidence was so construed as to imply the co-operation of experts in certain cases. In the middle ages, whether in civil or in ecclesiastical courts, and generally in the commercial and customary tribunals, the weighing of evidence was as careful as it has ever been. The introduction, in that period, of courts of inquest whose object was avowedly to procure condemnations, such as those of heretics, and the survival of certain ancient uses of the ordeal have obscured the prevalence then of careful taking of evidence.

In 1507 a penal code containing exact instructions relating to evidence was issued by a bishop of Bamberg, and in 1532 the Caroline code of the German states contained provisions for the examination of criminals. In 1575 a French physician described the form in which judicial reports should be made in medico-legal cases, and at the close of the 16th century outlines of the method of testifying in such cases were numerous, especially in Italy. Toward the end of the 18th century legal medicine was recognized as a science. Mathieu Orfila, who occupied the chair of chemistry and medical jurisprudence in the University of Paris, was employed as an expert in judicial proceedings; in 1813 he published a *Traité des poisons.* In 1689 Johannes Bohn, of Leipzig, published a work on the examination of wounds, the distinction between ante-mortem and post-mortem wounds, and the different effects of death by injury, strangulation and drowning. In another work, published in 1704, he gives rules for the conduct of physicians during court testimony. During the latter part of the 18th century German scientists published numerous books on the subject. Lectures in medical jurisprudence were given at the University of Edinburgh in 1792, and in 1806 the university gave the title of "professor of medical jurisprudence" to A. Duncan, Jr. Thomas Percival, with *Medical Ethics* (1803), made himself one of the first noteworthy English contributors to medical jurisprudence, and was followed by John Gordon Smith. In 1823 J. A. Paris and J. S. Fonblanque published the first English work which associated the medical and legal professions. In 1836 Alfred Swaine Taylor published *Elements of Medical Jurisprudence,* an authoritative work. The first Spanish treatise on legal medicine (1796–97) was written by Juan Fernández de Valles. In 1844 Pedro Mata of Madrid published a work on legal medicine and toxicology which, in subsequent editions, became the most important Spanish treatise on the subject. The fathers of the modern school of scientific investigation were Hans Gross, a professor of criminology; R. A. Reiss, of the University of Lausanne; and Alfred Niceforo.

The old trial-and-error method in criminal investigation was rapidly displaced in the 19th and 20th centuries by scientific methods, including the use of very highly specialized instruments. Philip VI of France had initiated the modern police system of criminal investigation. In Paris, as early as 1327, he appointed *commissaires,* or royal officers, who were not part of the judicial system and who conducted preliminary examinations in the enforcement of police regulations. The *maréchaussée,* a military police, was organized in 1356, becoming the *gendarmerie* in 1720. The first modern police organization, however, was founded in London in 1829. Twenty-five years later the Paris civil police were reorganized on the London model. In 1830 all ungarrisoned Prussian cities were authorized to establish a police force.

Large police departments usually divide their detective forces into two major parts. First, there are groups of detectives assigned to definite geographical areas and responsible for the investigation of crimes committed therein. Second are the specialized "squads" or "details," formed for the purpose of dealing with specific types of crime such as homicide, safe burglary, forgery and confidence games. These investigators are expected to possess special sources of information and an intimate knowledge of the special types of crime together with an acquaintanceship with the physical appearance, haunts and practices of known criminals.

With the development of rapid means of transportation the scope of an individual criminal's activity became greatly enlarged, and jurisdictional boundaries of police forces often hindered the success of an investigation. To combat this trend local police forces maintain close liaison with their neighbours by means of such methods of communication as teletype, telephone, radio and television. Photographs and fingerprint records can be transmitted coast to coast by wirephoto. In this manner the pursuit of a fugitive can be pressed by broadcasting his description together with information concerning his haunts and personal habits.

The complex organization of the modern state led to the establishment of large investigative forces within the various departments of the government. Thus, the military, post office, state and other departments maintain their own, independent investigative units to conduct inquiries into crimes affecting these departments. Since these investigations are often nationwide in scope, an elaborate system of report writing, mutual co-operation and centralized control has been developed. These agencies are also better equipped to cope with such crimes as espionage and sedition, which are directed against the nation as a whole and which, consequently, assume the form of a widespread conspiracy. In addition, the character of modern organized crime has tended to become increasingly complex. A key group of criminals, centrally located, may have representatives in every large city. Local police forces can deal with the problem only in a fragmentary way. A national investigative agency can form a coherent and unified picture of the crime situation and take necessary remedial measures with the co-operation of local police departments.

(A. Vo.; C. E. O'H.)

METHODS OF INVESTIGATION

Identification.—The major concern of criminal investigation is the professional criminal—the recidivist, whose name will appear periodically on the arrest record. If his identity can be conclusively established, his later efforts at concealment can usually be thwarted. A system whereby the identity of the criminal can be positively determined at each arrest is an invaluable aid to the investigator. The qualities of an effective identification medium are the following: (1) it should be fixed and unalterable by deformation or replacement; (2) it should be found on every person; (3) it should be unique for each person; (4) it should be susceptible of being recorded in a simple manner; (5) the records should be classifiable so that each person has a unique position in the files.

The search for a valid identification medium has been a constantly recurring quest in the history of investigation. Tattooing, branding, physical description, measuring and photography have had their successive vogues. The latter three methods, still in common use at mid-20th century, were established as techniques of identification by Alphonse Bertillon, chief of the identification bureau of Paris. He is best known for his development of the science of anthropometry in which an individual is identified by means of his bodily measurements. In the Bertillon system of identification, which he introduced in 1882, identification is completely accomplished by a series of refined bodily measurements, peculiar markings such as scars, and personality characteristics. Bertillon's system was later discarded by most police departments in favour of fingerprint systems, but his descriptive methods are used by investigators as an excellent means of furnishing a minutely descriptive verbal portrait of an individual.

Almost all large police departments possess an identification division where experts compile information which will assist the investigator in his work. The duties of an identification expert are as follows:

1. To ascertain identification of the perpetrator of the crime prior to his apprehension (*a*) by the use of the alphabetical index when the name of the offender is known; (*b*) by photograph when the criminal has been seen by his victim or by witnesses; (*c*) by the *modus operandi* of the criminal; (*d*) by the handwriting of

the criminal; (*e*) by finger impressions left at the scene of the crime.

2. To ascertain identification of offenders after arrest (*a*) by the alphabetical index; (*b*) by a photograph, where no fingerprints have been taken; (*c*) by the *modus operandi* system connecting the arrested criminal with numerous other crimes; (*d*) by comparison of the criminal's handwriting with documents connected with criminal offenses; (*e*) by finger impressions of the criminal found at scenes of crimes committed by him, of which he was not suspected by the investigator; (*f*) by the ten-digit fingerprint system when the offender has been previously recorded in the bureau.

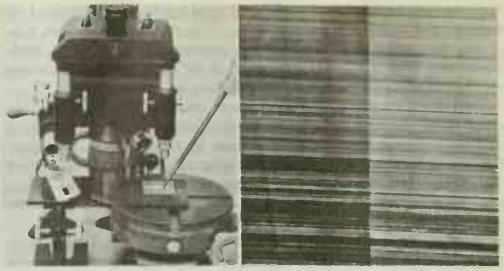
Fingerprints.—At the scene of the crime the investigator endeavours to discover the criminal's latent fingerprints, which he can "develop" or make visible for photography. The latent print is a thin layer of perspiration or grease deposited in the pattern of the friction ridges. Hard, glossy objects such as glass and enamel paint present ideal surfaces for the development of latent fingerprints. Dirty objects and absorbent materials do not readily bear prints. On smooth surfaces the print is made visible by carefully applying a fine powder of suitable colour with a brush. The powder adheres to the small amount of fat present in the perspiration or to the grease which frequently lies on the fingers. Chemical treatment such as iodine fuming or a 5% silver nitrate bath is used to develop fingerprints on paper, wood or other surfaces. The silver nitrate reacts with the sodium chloride present in the perspiration to give silver chloride, a light-sensitive substance that darkens on exposure to a bright light source to reveal the fingerprint pattern. The developed print is preserved by photography, by lifting or by retaining the object itself on which the print appears, and is filed for subsequent comparison with the prints of suspects. It is difficult, however, to discover the identity of a person from a single finger impression left at the scene of the crime, even though the criminal's fingerprints are filed in the identification bureau, unless the subject's prints are also classified in a single-fingerprint file or unless the person's name is known.

Frequently the victim of a crime or a disaster cannot be identified readily by common means of recognition. In such cases special techniques are required in order to obtain classifiable fingerprints. In addition to fingerprints, a person may be identified by X-ray studies, tattoos, anatomical data, occupational marks or dentures. (*See* FINGERPRINT.)

Modus Operandi.—If successful, criminals have a tendency to use the same techniques in their operations. Often the procedure is highly characteristic and will serve to identify the criminal and enable the police to attribute a series of crimes to one offender. Classification of criminals by their methods of operation thus became a permanent and invaluable feature of investigation. Some departments use the Atcherley *modus operandi* system for this purpose. L. W. Atcherley, originator of this system, utilizes the following classes:

1. *Classword*—kind of property attacked, whether dwelling house, lodging house, hotel, etc.
2. *Entry*—the actual point of entry, front window, back window, etc.
3. *Means*—whether implements or tools used, such as a ladder, jimmy, etc.
4. *Object*—kind of property taken.
5. *Time*—not only time of day or night, but whether church time, market day, during meal hours, etc.
6. *Style*—whether criminal describes himself as mechanic, canvasser, agent, etc., to obtain entrance.
7. *Tale*—any disclosure as to his alleged business or errand which the criminal may make.
8. *Pals*—whether crime was committed with confederates, etc.
9. *Transport*—whether bicycle or other vehicle was used in connection with the crime.
10. *Trade-Mark*—whether criminal committed any unusual act in connection with the crime, such as poisoning a dog, changing his clothes, leaving a note for the owner, etc.

Investigation and Reference Files.—Informational files are maintained by police departments to assist the investigator in his efforts to trace the fugitive from justice. The primary purpose of these records is to indicate the source of evidence discovered in connection with a crime. For example, a file of automobile tire patterns will assist in identifying a tire impression found at the scene of a crime. Automobile registrations and records of firearms will assist in establishing ownership. In addition to their own files the police have recourse to the records of the many governmental agencies that record titles, contracts, significant events and official acts in general. Among other files maintained by the police the following prove exceptionally useful:



BY COURTESY OF THE CHICAGO POLICE DEPARTMENT

MATCHING TOOL MARKS: (LEFT) TOOL IMPRESSED ON PLATE LEAVES STRIAE CAUSED BY MANUFACTURING IMPERFECTIONS; (RIGHT) TEST STRIAE MATCHED UNDER MICROSCOPE WITH STRIAE TAKEN FROM SCENE OF BURGLARY IDENTIFIES TOOL AS ONE USED IN CRIME

Missing Persons.—Each year thousands of persons are reported missing to the police. In addition, the police must investigate cases of unidentified persons, living and dead. Descriptive files are maintained of missing persons under the age of 21, unidentified dead, and unidentified persons who are physically and mentally afflicted.

Laundry and Dry Cleaner's Marks.—One of the best clues to the identity of an unknown person is the mark in his clothing placed there by the laundry, dry cleaner or tailor. The dry cleaner, for example, identifies each article of clothing received by means of a set of numbers and letters. These marks are kept in a systematic file by larger police departments for the purpose of tracing a lost, dead or wanted person by means of clothing, whether found on his person or at the scene of a crime. Each mark is associated with an individual laundry, dry cleaner's or tailor's establishment, which can often give the investigator the address of the wanted person. In some cities more crimes are solved by means of this file than through the medium of latent fingerprints.

Lost or Stolen Property.—Many burglaries are solved merely by tracing stolen property to the possession of the criminal. For this purpose police maintain a central cross-indexed file of property lost and articles of value pledged at pawnbrokers or sold to secondhand dealers. The common objects of larceny—automobiles, watches, jewelry, furs and cameras—usually bear identifying serial numbers or marks.

If the criminal disposes of the stolen article through a pawnbroker or a secondhand dealer, the police may trace him through the record of sale which is forwarded to them by the dealer, as required by law in some cities.

COMMUNICATIONS CENTRE: SYSTEM OF RADIO CONSOLES PROVIDES DIRECT COMMUNICATION WITH POLICE VEHICLES. INTEGRATED WITH CITY TELEPHONE NETWORK, EMERGENCY CALLS ARE TRANSMITTED TO CONSOLE SERVING THAT ZONE

Informants and Surveillance.—In combating crime the police require an effective system of positive intelligence. Owners of licensed premises, cab drivers, bartenders and others whose business involves contact with the public at late hours are excellent sources of information. Their co-operation can be enlisted without any difficulty because of the nature of their occupations. In some countries criminals, prostitutes, gamblers and other underworld characters are employed as undercover

agents and report regularly to one or more contact officials. A safe burglar lavishly spending money; a bandit suffering from gunshot wounds; an automobile thief with stolen licence plates; a pawnbroker buying "hot stuff"—all these are types of instances reported to contact officials by undercover agents. Apart from the regularly employed undercover agents, individual investigators obtain information from criminals and other persons whom they have befriended.

It is customary in some courts for the judge to instruct the jury to weigh with extreme care the testimony of informers and accomplices, since their credibility is particularly vulnerable to attack on the grounds of character as well as motivation. In general, a conviction cannot be had upon the testimony of an accomplice unless corroborated by other evidence. A confession of the accomplice cannot be used against another offender unless it is made in court or unless the confession was made in the presence of the accused and he made no reply or otherwise failed to deny it.

Where the services of an informant cannot be obtained, the investigator can initiate a surveillance of criminal activities. This may be done by covert observation or by arranging to have a police agent work within the criminal group, ostensibly as one of them. When this method is successfully employed, it is extraordinarily effective since it provides the direct testimony of a reliable witness. Past crimes can be solved and projected illegal ventures anticipated. Another form of surveillance is the "planting" of microphones and "tapping" of telephone lines. Radio communication can also be employed.

Legal difficulties are encountered with evidence obtained through tapping telephones or planting microphones. The United States code prohibits the use of information acquired by tapping a telephone as evidence against an accused, if he is being tried in a United States district court. State courts are less rigorous in the limitations they place on evidence of this nature, some permitting the interception of telephone messages if a court warrant is first obtained. In regard to information acquired by means of concealed microphones, federal courts have ruled that such evidence is permitted if the microphone is installed without committing a trespass. For example, placing a contact microphone on the opposite side of the wall of the hotel room of a subject would not constitute a trespass.

Interrogation.—Since the purpose of a criminal investigation is to discover the truth of the facts surrounding a crime, obviously the shortest road to this goal is to obtain a confession from the guilty person and to elicit significant information from witnesses and informants. The skilful interrogation of a suspect is often the key to a successful investigation. Experience, shrewdness, patience and imagination are required for effective questioning. Guile, forcefulness of character and practical psychology must be employed without resorting to duress or other violation of the suspect's rights. The interrogation is, therefore, a delicate proceeding, since a confession obtained in violation of the suspect's rights can be repudiated in court.

The skilful interrogator briefly analyzes the character of the subject and estimates his weaknesses. Experimentally he assumes different attitudes and employs various procedures to determine the most effective technique of questioning the subject. If he can enlist the subject's co-operation, a confession will be forthcoming. In the case of a reluctant or obstinate subject, he will endeavour to lead him into contradictions, inconsistencies and improbable statements, thus showing him the futility of continued deception.

The most difficult of all subjects is one who flatly refuses to talk about the case. In these situations, the investigator, who must respect the rights of the subject, is usually forced to abandon the interrogation and rely on other types of evidence.

Detection of Deception.—The act of lying is ordinarily accompanied by a bodily reaction such as flushing, increased heart beat, swallowing or other evidence of emotional reaction. Some understanding of the practical psychology of lie detection has always been part of man's knowledge. The 20th century saw the introduction of a number of efforts to apply instrumentation to the art of detecting deception. These instruments are called "polygraphs," "deception indicators" or "lie detectors." Their function is to produce a record of physiological phenomena which may be used as the basis of applying a technique for diagnosing deception. The success of a deception indicator depends on the sensitivity of the mechanism, the phenomena chosen for record and the ability of the operator. It cannot be stressed too greatly that the greatest single factor in the success of a lie-detection technique is the professional capacity of the operator.

The phenomena which should be chosen for recording are those that are not subject in any great degree to voluntary control and which, moreover, are such that the subject is not usually aware of them. Experts in the field consider blood pressure, pulse and respiration as the most dependable criteria. The electrodermal response or current flow between two different areas of the body is also considered useful. To these was added the unobserved muscular activity which has been found to affect the blood pressure. None of these phenomena is a sufficient indicator in itself, but taken together their recording offers an effective means of determining deception. The blood pressure-pulse-respiration recorder employs pens to record impulses on moving graph paper driven by a small synchronous electric motor. A pneumograph tube is adjusted around the subject's chest and a blood pressure-pulse cuff is strapped around the arm. The examiner first acquaints himself with the details of the case. He establishes norms of reaction by asking preliminary questions of an irrelevant nature and then injecting questions pertaining to the investigation. Three or four lie-detector records are ordinarily required for a diagnosis.

PNEUMATIC POLYGRAPH. GRAPH ON LEFT RECORDS BLOOD PRESSURE (CUFF ON UPPER ARM); RESPIRATION (RUBBER TUBE ON DIAPHRAGM); MUSCULATORY MOVEMENTS (CYLINDER UNDER LEFT ARM); SKIN REFLEXES (ELECTRODES ON FINGER TIPS)

A study of the graphical records and an evaluation of the deviations caused by certain responses will reveal unusual emotional activity.

Although the lie-detector test proved a great boon to the investigator, information obtained by this means is not generally accepted as direct evidence in the United States courts of law. Many court decisions denying recognition to this evidence have been based on the contention that the technique has not won general scientific acceptance. In the event that these tests are accepted as competent legal evidence, it is anticipated that the question of compulsory tests will give rise to legal disputes as to whether they affect the subject's privilege against self-incrimination.

SCIENTIFIC AIDS

Police Laboratory.—With the rapid advance of scientific methods of analysis, physical evidence such as paint, dirt and fibres assumed increasing importance as sources of clues. After 1920 the larger police departments endeavoured to employ experts for the purpose of examining evidence at the scene of the crime and at the laboratory. These police scientists are distinguished from medical examiners in that the latter are ordinarily concerned with homicides and then only with regard to the cause of death and the nature of the fatal weapon. The police laboratory expert, however, must deal with a wide variety of crimes and with all the

possible clue materials that can be used to provide evidence. The application of the physical sciences to the detection of crime is sometimes called scientific criminology or, more specifically, criminalistics. Chemistry, biology and physics are the major branches of knowledge employed in examining evidence.

The physical evidence found in connection with a crime may be divided into two classes. In the first the evidence constitutes part of the corpus delicti; it is one of the essential facts of the crime. Thus the white powder found on the person of an alleged narcotics seller constitutes an essential part of the crime. It must be identified as being a particular narcotic such as heroin or morphine. Poisons and other substances used illegally fall into this category. The second class consists of associative evidence, clue materials which link a suspect to the scene of the crime and thereby establish a higher probability of his guilt. A suspect, for example, apprehended near the scene of a burglary may have glass fragments in the lining of his trouser cuffs. A spectrographic analysis of the glass fragments may show that the chemical composition is the same as that of a broken glass window at the scene of the crime, thus connecting the suspect with the crime. Similarly a foot impression at the scene of a murder can be traced to the owner of a particular shoe; a flake of paint at the scene of a motor vehicle accident can be connected with a definite automobile; a tool mark can be matched with the defects in the blade of a burglar's jimmy. In all these comparisons the aim of the investigator is the same as that of the fingerprint expert: to discover a sufficient number of characteristics in the evidence to connect it uniquely with a known source by the laws of probability.

Chemical Analysis.—The forensic chemist ordinarily performs the relatively few biological examinations as well as the chemical analyses associated with criminal investigation. In cases of homicide the medical examiner makes the examinations connected with the autopsy and the cause of death. In the field of biology the chemist is primarily concerned with blood and semen stains. Semen stains occur in connection with rape cases, and their analysis is a simple microscopic examination to discover spermatozoa. Blood stains are found quite commonly in assault cases. A preliminary field test such as the benzidine or the phenolphthalein test is used to establish the possibility that the stain is blood. These tests require only a minute stain area. To establish the fact that the stain is blood, the Teichmann hemin crystal test or spectrophotometry is used. The precipitin test, employing a larger area, may then be used to determine whether the blood is human. Depending on the amount, age and preservation of the stain, the blood may be grouped into one of the four major divisions and in some cases into the subdivisions.

Microanalysis is employed by the forensic chemist to study structures by means of the compound microscope. Minute quantities of trace materials can be identified and their source determined. Plants and animal tissues, vegetable, animal and synthetic fibres, sand, soil and minerals are recognized and their connection with the case under investigation is established.

Deposits found under fingernails and dust or stains found in or attached to clothing or weapons have furnished the investigator with significant clues. Hair can be identified as human and the race of the person determined from it. It is not, however, possible to identify hair as belonging to a single individual. At best a similarity can be established.

The most challenging problem of the police chemist is the analysis of a minute sample of material such as paint or glass to determine the source of the substance. If sufficient trace elements and impurities are present, the sample can be connected uniquely with the source material. A stain on a suspect's shoe can be shown to have been acquired at the crime scene. The spectrograph serves well in this work.

Instrumentation has provided other techniques of rapid chemical analysis such as X-ray diffraction, infrared, visible and ultraviolet spectrophotometry, and electron microscopy. These instruments can deal with minute samples, which are often the only clue present, and can reveal physical or chemical characteristics so great in number, so diverse in nature or so rare in occurrence as to preclude all but a negligible probability of duplication by coincidence. They permit analysis without disturbing the sample, thus making it possible to keep the evidence intact for presentation in court and for tests by the defense.

Moreover, a police scientist does not have to be an expert in every branch of chemical analysis to use these instruments effectively. A reasonable familiarity with the techniques, the basic materials, the fillers and the accidental trace elements of the industries from which his samples come is usually sufficient.

Photography.—Of the technical aids available to the investigator the camera is by far the most important and the most widely used. The full resources of photographic science are employed: photography through the spectral range from the infrared region to gamma rays; photomicrography; microphotography; cinematography; orthostereoscopy; radiography in the hard and soft X-ray regions; and electron photomicrography. Six major functions are served by investigative photography: (1) for identification records, it provides a picture of the criminal or missing person; (2) in conducting a surveillance the camera can be used to obtain a visual record of the illegal activities; (3) the original appearance of the scene of the crime can be preserved for the court's consideration; similarly, a re-enactment of the crime can be recorded in motion pictures for court demonstration; (4) the initial appearance of evidence can be photographed before it is submitted to necessary changes by the police laboratory; (5) the camera can be used to reveal hidden aspects of the evidence; by the employment of filters or magnification certain details and relationships of the evidence can be revealed and emphasized to prove a point in question; (6) to demonstrate investigative findings to the court the photograph serves as an invaluable visual aid. Court exhibits in the form of photographic enlargements vividly supplement the testimony of investigators and laboratory experts and provide a meeting ground for the contentions of opposing counsels.

Document Examinations.—A great part of the work of a police laboratory is concerned with the examination of questioned documents. Problems of handwriting, typewriting, paper and ink are continually arising in connection with investigative work, particularly that dealing with forgery and anonymous letters.

The classical problem of document examination is the com-

parison of handwriting to determine the true author of a questioned document. At its simplest this problem is a straightforward comparison of the questioned writing with the known writing of a suspect. Such a case would occur, for example, in connection with a threatening letter or a ransom note.

The more difficult problems are those of forgeries and disguised writings. To establish the identity of the author of a questioned writing the document expert searches for certain characteristics of penmanship. Only a small part of an adult's handwriting is written consciously. The greater part is written without adverting to mechanical details. It is for this reason that a forger cannot imitate another person's writing exactly and will include, unconsciously, fundamental movements ingrained in his own writing habits. Line flow, relative slant, pen pressure, letter connections and spacing, line curvature, tremor, proportion, base alignment and shading are the most important characteristics. These elements, if sufficiently individual, will serve to identify the writing. In a successful handwriting examination there must be an adequate combination of significant similarities between the questioned and the known writing without any unexplained major differences. (*See* also HANDWRITING.)

Typewritten documents offer kindred problems, although here the emphasis is on identifying the machine and thus indirectly locating the author of the document. Among the questions which the expert is called upon to answer are the following: was the questioned writing typed with *this* typewriter?; what is the make and model of the typewriter used?; was the entire document written with the same typewriter?; does the model of the typewriter set a maximum age to the writing? The identification of a typewriter as being uniquely the machine employed depends upon the discovery by the expert of a set of individual characteristics of the type faces.

In examining a specimen of typewriting the expert studies the design, alignment, slant, footing and defective forms of the letters. Most typewriters possess individuality with respect to the alignment of the letters and the relative perfection of the type faces. Normal wear and abuse introduce additional defects. The resulting set of characteristics is often sufficiently numerous to establish the unique character of the typewriting and the machine.

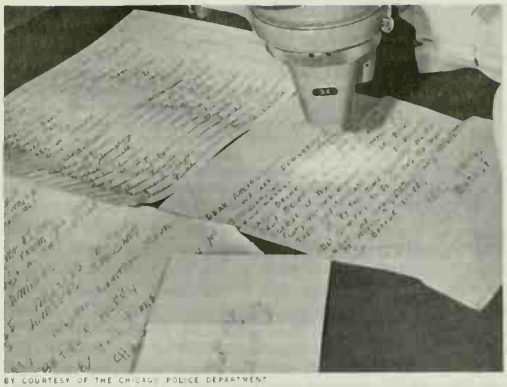
The detection and deciphering of alterations is another major problem of document examination. Checks, wills, insurance policies, passports, licences, birth certificates and other official records are often altered by erasing or obliterating. By examining such a document with the aid of a microscope or under ultraviolet light the erasure or obliteration may become apparent. Deciphering is ordinarily achieved by chemical methods and by special photographic techniques such as the use of infrared films.

Photography is also the most effective method of revealing the writing on charred documents, carbon paper and on the indentations of the undersheet of a pad or checkbook. Chemical methods are employed to detect secret writing, to differentiate types of ink and to estimate within broad limits the age of an ink writing.

Although the investigator is assisted by technical aids, such as the crime laboratory, the medical examiner's autopsy and toxicological studies, he must rely mainly upon his own physical and mental resources to provide a solution to the crime that he is investigating. He must be a student of people in all aspects and must be thoroughly familiar with law, normal and abnormal behaviour, and the wide variety of ways by which crimes may be committed.

Firearms.—The development and distribution of firearms have made their study a highly complex field for the specialist. Information of value in criminal investigation may be obtained by expert examination of guns, bullets, cartridge cases, pellets, wads, powder burns and powder deposits.

Firearms vary in calibre, type and design, and bullets fired from them (as well as expended cartridge cases) have certain characteristics that help to identify them. Rifled firearms have a number of spiral grooves, commonly from two to seven, cut in the barrel. The width, depth, angle and direction of these grooves vary with different makes, models and calibres; portions of the bore remaining between these grooves are known as



BY COURTESY OF THE CHICAGO POLICE DEPARTMENT

MICROSCOPIC COMPARISON OF ANONYMOUS HAND-PRINTED EXTORTION NOTE WITH KNOWN WRITING OF SUSPECT

"lands" and possess specific dimensions. The markings found on a fired bullet show a general consistency with certain calibres and types of firearms, as well as specific inconsistency with many others. When a suspected firearm is obtained, test bullets are fired into a suitable medium, such as cotton, oiled sawdust or water, and are recovered and compared with the evidence bullet.

As a result of its manufacture, use and abuse, each firearm acquires certain distinguishing characteristics, some of which leave their marks on the surface of fired bullets; the marks that take the form of groups of fine lines are called striae. By using a comparison microscope, whereby a single image composed of portions of images of the test and evidence bullets is created, the expert is enabled to evaluate the coincidence of striations, judge the degree of "match," and conclude that a specific gun did or did not fire a specific bullet—or that insufficient markings are available for a conclusion. As in other aspects of criminal investigation, the skill and experience of the examiner are of paramount importance in this work. There is always some coincidence whenever two different sets of similar fine lines close together are compared; experiments indicate that the degree of false coincidence ranges from 12 to 22%. The degree of coincidence required for a positive bullet identification is a matter of opinion. Some examiners require positive comparisons of three different sides of the bullet (Burrard), others require at least three separate grooves (Churchill) and still others require the entire circumference (Goddard). Evidence bullets are sometimes defaced or distorted, thus interfering with their evaluation; experienced investigators may be able to reach definite conclusions in about 60% of their examinations of bullets.

The cartridge case is also marked (by the extractor and ejector) and its primer frequently receives an imprint from the breech-face in addition to a firing pin impression; thus a recovered cartridge case presents opportunities for microscopic examination similar to those of a recovered bullet.

Defaced serial numbers may sometimes be sufficiently restored by chemical or electrochemical techniques; through such numbers the ownership of the firearm may be traced.

Careful examination of powder burns and powder deposits may indicate how close the victim was to the firearm at the time of discharge. They may also tell how a firearm was held at the time of discharge; idiosyncrasies of specific firearms mechanisms may support or refute such testimony.

In addition to firearms, the firearms expert is also concerned with flare pistols, tear gas devices, blank cartridge guns, air, gas and spring guns, humane slaughtering devices and powder-actuated tools. (S. BN.)

INVESTITURE CONTROVERSY. Investiture is the formal installation into an office or estate by a superior authority. In medieval European law it had special reference to the feudal relation between suzerain and vassal: the suzerain received the homage and oath of the vassal and invested him with a piece of turf, a banner or branch, symbolic of the authority conferred on him. Later the sword and sceptre became the common symbols of lay investiture. In the investiture of ecclesiastics, the ring and crosier were the accepted symbols of ecclesiastical authority.

Investiture had its main historical interest in connection with the relations between the medieval civil and ecclesiastical authorities. Since bishops and abbots were often not only ecclesiastical lords but also lords of fiefs, they possessed both civil and ecclesiastical authority. This led to a conflict between civil and church rulers, each of whom considered the bishop or abbot to be his representative. The struggle over the right to invest bishops and abbots, which absorbed several popes and emperors of the 11th and 12th centuries, was one of the most important aspects of a larger struggle for power between papacy and empire, and its outcome was significant for the political history of the later middle ages.

After the time of Charlemagne civil rulers had usurped almost complete control over appointments to bishoprics and abbeys, which added greatly to their power and revenues; lay rulers were able to prevent free canonical elections, keep bishoprics and abbeys vacant for years, sequestering their funds, and sell church offices to the highest bidders. In asserting this control they claimed the right to confer on ecclesiastics the symbols not only of civil power but the crosier and the ring as well. The psychological effect of this was to persuade the populace, most sensitive in the middle ages to allegory and symbolism, that the lay prince was the source of religious as well as of civil authority. In turn, bishops and abbots, and particularly the bishops of the Holy Roman empire, became increasingly "king's men," to the detriment of their spiritual obedience and obligations. When in the 11th century the pope sought to break lay control of ecclesiastical office, he clashed first with the German emperor.

The spirit of reform that dominated the papacy of the 11th century was best expressed in the program announced in Rome at the Lenten synod of 1075 by Gregory VII, which forbade lay investiture, deposed simoniacal clerics and condemned clerical marriage. In retaliation the emperor Henry IV, with the support of the German bishops, attempted to depose the pope. Germany and northern Italy were torn by a controversy that did not end till 1122, when Pope Calixtus II and the emperor Henry V agreed on the concordat of Worms. Its provisions were reaffirmed by the first Lateran council (1123). The emperor renounced the right to invest with ring and crosier, but he continued to control appointments to bishoprics and abbeys.

In France lay investiture had a similar development, but because of the weakness of the monarchy during the 11th century no common royal policy existed. The church's dealings were primarily with powerful local nobles. By 1200 the kings had abandoned lay investiture, but they continued to control appointments to major benefices.

After the Conquest in England, William I frequently violated the canon law in his dealings with the church, but since he was a strong supporter of reform he continued to enjoy the support of the papacy. A minor lay investiture controversy arose under William II (Rufus) and Henry I, when the latter sought to force Anselm to pay homage for the ecclesiastical holdings of Canterbury. This dispute was finally settled by compromise in 1107; as on the continent, the king continued to make most appointments to major ecclesiastical benefices, but freedom of election was guaranteed.

INVESTMENT BANKING. In a broad sense, investment banking embraces all the institutions and processes by which capital formation takes place, including: (1) the transfer of ownership of existing wealth through brokerage houses; (2) security substitution, such as is involved in the issuance of securities by investment companies; and (3) security management, or the decision as to where investors' funds are to be placed. In a narrower sense, investment banks are firms which originate, underwrite and distribute new security issues of corporations and government agencies.

It is often said that modern production is "capitalistic" in the sense that it requires large amounts of capital for successful operation. This need for capital explains to a significant degree the shift from the sole proprietorship and the partnership to the corporation as the dominant legal form of business organization. Individual proprietorships and partnerships can for the most part look only to their owners, one or a few, as sources of funds. Corporations can obtain funds from thousands and hundreds of thousands of owners (shareholders) and can obtain these funds by varying the terms of successive stock issues in such a manner as to make the most effective appeal to prospective stock purchasers. In addition, corporations can borrow funds and can tailor their debt contracts to the requirements of lenders. The corporation has access to larger amounts of funds because it can offer a greater variety of security contracts and thus can adapt itself to the willingness or unwillingness of investors to take risks. Bonds (debt contracts) can be offered when investors demand safety; stocks (equity contracts) can be sold when investors are willing to take greater risks for the opportunity of greater gains.

The market for funds, the commodity with which investment deals, is made up of the demand for funds and the supply of funds. Three important parts of the demand for funds may be distinguished. The business demand for funds has already been mentioned. Similarly, governments and public authorities demand funds for the construction of public buildings, highways and governmentally owned utility plants. Third, consumers enter the market to borrow funds to finance the purchase of homes and other durable consumer goods. The supply side of the funds market is made up of four parts. Individuals save portions of their incomes and make their savings available in the funds market through the purchase of bonds, stocks and mortgages. Financial institutions (insurance companies, savings and loan associations, investment companies) and nonfinancial institutions (churches, hospitals, universities) receive funds from individuals and make them available to fund users by buying securities. Business corporations provide funds by retaining portions of income earned and using this income to purchase operating assets, thus supplying some of their own demand for funds. And governments may provide funds by collecting taxes in excess of current expenses and investing the funds in outstanding government security issues.

Institutions in the Funds Market.—Financial institutions

are sometimes called fund-aggregative institutions. They obtain funds through some form of arrangement with those whose investments they manage. For example, insurance companies obtain funds through the receipt of premiums on policies; commercial banks and savings banks receive deposits; and investment companies sell shares. These institutions then purchase government bonds or bonds and stocks of corporations which are in the market for funds. Institutions operating in this manner gather together the small funds of many individual investors and attempt to provide such investors with a better diversification and a more skilful management of funds than the individual could have achieved through his own efforts. Individual savers, instead of buying bonds or stocks of operating companies directly, place their funds with financial institutions of the fund-aggregative type, which in turn offer them in the funds market. This means that corporations and governments seeking funds must take note of movements of this kind and must note also the interest rates current at the time of the contemplated issue.

A second class of financial institutions in the field of investment banking engages in the marketing of securities. Such institutions are not on the supply side of the market, as are the fund-aggregative institutions, but are between those who demand the funds and those who supply them; they endeavour to bring the two sides of the market together with as little friction and cost as possible. Securities marketing institutions are divided into two groups: institutions which facilitate the original distribution of securities from corporations to investors; and those which assist investors to trade among themselves in securities which corporations have issued some time in the past. Marketing institutions which purchase security issues from corporations and sell them to investors are often spoken of as investment banking firms, but it should be noted that investment banking in the proper sense encompasses all the institutions, processes and procedures by which funds are transferred from savers to users. Marketing institutions having to do with "old" or already-issued securities are in turn subdivided into two classes: the securities exchanges, together with the members and member firms which buy and sell securities on the floors of these exchanges; and the over-the-counter market, made up of security brokers and dealers who buy and sell through contacts provided by the telephone, the telegraph and the teletypewriter.

Financial houses dealing in securities which have been outstanding for some time aid in the transfer of funds in several ways. Corporations desire to have their outstanding securities sell at as high prices as possible since the prices of these securities determine the prices at which new securities can be issued and thus determine the cost of new funds. For example, if a corporation's stock is selling at 40, the firm cannot sell a new issue of stock having the same contractual features at 60, for no one would buy it. Often a corporation will find it to its advantage to list its securities on a securities exchange. (*See* LISTED SECURITIES.) Trading on the floor of an exchange takes place among individuals who are members of the exchange. Those who are not members can use the facilities of the exchange by employing a member, through a member firm of which the exchange member is a partner, to trade on the floor for a commission paid to the member firm. (*See* STOCK EXCHANGE.)

The securities of most corporations are not listed on an exchange, but are bought and sold among investors through purchases from and sales to dealers. This is the over-the-counter market (*q.v.*). A dealer may buy a security from an investor and sell it to another investor, or may sell it to another dealer who in turn sells it to one of his investor clients. Most small and medium-sized corporations find that the interest in and sponsorship of their securities provided by a dealer serves to maintain prices at higher levels than if the securities were listed. Practically all trading in government bonds and most trading in corporate bonds takes place in the over-the-counter market. Since the stock issues of the largest corporations are listed on exchanges and since the stocks of these companies are traded in more frequently, it is probable that the volume of trading in stocks on the exchange exceeds that on the over-the-counter market, but many classes of stocks are traded predominantly in the over-the-counter market, particularly the stocks of insurance companies, banks and mutual investment companies.

Acquisition of New Funds.—The next consideration is that of investment banking in the narrower sense, the origination, underwriting and distribution of new security issues. Corporations obtain funds from two major sources on the basis of the term of the contract with the supplier of the funds. Short-term funds which must be repaid within one year are obtained from commercial banks, from trade creditors and from the government in the form of accrued tax liabilities. Long-term funds are obtained from individual and institutional investors through the sale of securities to these investors. These funds may be acquired from investors as creditors through the sale of bonds and mortgages, or from equity investors through the sale to owners of shares of stock or through the retention in the business of earnings which might have been paid to the owners as dividends. It is the function of investment banking firms operating in the new-issue market to assist corporations to acquire new long-term funds. Corporations use these funds to enlarge their operating assets or to pay off maturing security issues.

The investment banking house operates by purchasing all of the new security issue from a corporation and selling the issue in smaller units to the investing public. It buys from the corporation at one price and attempts to sell to investors at a higher price, a price sufficiently high to cover expenses of sale and leave a profit. Since the expenses of undertaking the sale may be relatively large for small issues, small and new corporations often find it uneconomical to pay the required "spread" of the investment bankers. Such corporations may obtain funds privately by sale of stock and bond issues to friends and relatives of the management and to employees without the intermediation of an investment banking firm. In other cases investment banking houses decline to assist new and small companies because they believe that the risks of investment in these companies are too great, and they are unwilling to recommend to their clients that the securities be purchased. As a result, investment banking firms are used to a much greater extent by companies which have lived through the first few difficult years, are now able to present a good earnings record and show promise of being able to make profitable use of additional funds.

Often a corporation seeks funds from its common stockholders by offering them the opportunity to buy more shares of the common stock issue presently outstanding. These shares may be offered to present shareholders at a price of, say, 40 even though the price of shares currently outstanding is 50. If the price falls below 40 before the new shares have been sold, the corporation will be unable to sell any more at the offering price, the stock offering will be a failure and the corporation will not have all the funds it planned to acquire from the issuance of the shares. To meet such a contingency the corporation will make a contract with an investment banking firm whereby the latter agrees to buy from the corporation at a price of 40 all shares which, by a certain date, have not been taken by the stockholders. In this way the corporation is assured of getting the funds it needs. The investment bank is paid a few cents a share for assuming the risk that it will have to take the shares, and a larger compensation per share for those shares which it has to take at the end of the period and sell to the general public. This arrangement is often called a pure underwriting contract or a stand-by underwriting.

The Mechanics of Underwriting and Distribution.—The typical underwriting arrangement involves the purchase of a security issue from a corporation by an investment banking firm or a group of such firms, and the sale of the issue to the general investing public, institutional investors as well as individuals. This procedure is followed in the case of bond issues of corporations as well as for stock issues which are not required by law or by decision of the board of directors to be offered first to old shareholders. The first step in the origination of a new security issue is a conference between officials of the corporation and the investment banker to determine whether the issue is feasible. The buying department of the investment bank conducts a preliminary investigation and decides whether the assets and earning power of

the corporation are such that it can recommend the securities of this company to its clients. This action is followed by conferences in which it is decided what amount and type of security is best suited to the corporation's needs. When this has been accomplished the formal documents in connection with the issue are prepared. In the United States the issue must in most cases be registered with the federal Securities and Exchange commission. Also a prospectus describing the security must be prepared and sufficient copies printed so that a copy may be given to each investor considering purchase. The arrangements between corporation and underwriters are set forth in a purchase agreement.

The underwriting and distribution of most security issues involves the organization of a syndicate of investment banking firms. When a corporation puts out a $100,000,000 bond issue no one investment banking firm wishes to take the risk of purchasing the entire issue. Therefore the investment bank which initiates the issue with the corporation organizes a group of investment bankers to divide the liability for the purchase, with the originator acting as manager of the group. Each member of the purchase group agrees to take a specific part of the entire issue. This arrangement is formalized in a contract called a purchase group agreement, or agreement among underwriters.

Distribution of the issue is effected through sale to individual and institutional investors. Most syndicate firms have distribution facilities and are able to dispose of the portion of the issue they have underwritten. Frequently the market coverage which can be obtained by the members of the syndicate is deemed insufficient, so selected dealers are used to bring about a wider distribution. These dealers are not members of the underwriting syndicate and they are obligated to sell only that portion of the issue they have subscribed for. Members of the syndicate pass along the securities to dealers at a reduction from the publicly offered price. This concession, as the reduction is called, reimburses the dealer for his expenses and provides him a profit if the distribution is performed skilfully. When distribution takes place through dealers, the members of the syndicate may be thought of as wholesalers who purchase from the manufacturer (the issuing corporation). These wholesalers sell some of the issue themselves to large consumers, particularly institutional investors, and sell the remainder to retail dealers who in turn sell to small investors.

Determining the Price.—One of the most important problems in security distribution is the pricing of the issue. There must be a decision first on the public offering price, the price which investors are to be asked to pay. If this price is too high, the issue will not be sold and the purchase group will bear a heavy loss. If the offering price is too low, the issue will be sold quickly but it will rise above the offering price immediately after issuance and the corporation will be dissatisfied with the price received. The major responsibility for setting the offering price rests on the investment bank, since it is in close contact with the market, is familiar with current interest rates and yields, and is best able to judge the probable demand for the issue in question.

The underwriters pay to the corporation a price which is lower than the public offering price by the amount of the spread. The spread is affected by the costs which the investment bankers anticipate in marketing the issue, by the difficulties foreseen in selling the issue at the offering price and by competition among investment bankers to obtain the issue for sale. The spread is divided into three parts, a fee to the originator of the issue, compensation to the members of the purchase group for undertaking the risk and a commission to the members of the selling group for selling the securities to investors. When new securities are to be issued the investment firm having close contact with the corporation is likely to be asked to originate the issue. This process is often called private negotiation. An alternative arrangement is competitive bidding. The corporation may itself settle upon the terms of the issue to be offered, and then invite all banking firms to submit bids. The issue will be sold to that firm which bids the highest. Competitive bidding has increased in importance in the United States, partially because it is favoured by the federal Securities and Exchange commission.

The investment banking system plays a significant role in the process of capital formation by transferring funds from savers to users. It is an extremely dynamic system, and adjustments to adapt it to changing conditions take place continually.

See Investment Bankers Association of America, *Fundamentals of Investment Banking* (1949). (M. D. Kn.)

INVESTMENT PAPER. The term investment paper, or, commonly, corporate or investment securities, applies to bonds, debentures, share certificates, collateral notes, equipment trust certificates and the like. Though called securities, not all such paper is issued upon mortgage or other security; and, though usually issued by a corporation, this too is not a requisite. The financial community divides investment paper—by issuer—into four main categories: governments, rails, utilities, and industrials.

Bonds and Debentures.—It is not clear what were the antecedents of the bond. The East India bond before the court in *Glyn* v. *Baker*, 1811, commenced as a receipt, "The United Company etc. do acknowledge to have received of W. G. Sibley 100 *l.*" (£100) and ended with an indemnity clause "in the penal sum of 200 *l.*" But midway it contained a promise to repay 100 *l* "to the said W. G. S. his executors, Etc. (by indorsement hereon)," and it was urged that this made for negotiability. The court, however, was clear that instruments of the sort were not negotiable "like bills of exchange." Parliament provided soon afterward that East India bonds were negotiable.

In the U.S., during the early part of the 19th century, great numbers of bonds were issued by states and counties in a frenzy to build canals and railroads. Like the modern bond these were elegantly engraved instruments, thrice the size of a merchant's note, and with the seal of the issuer "conspicuously put"; all with an eye to inspire confidence. But there were almost as many frauds as bond issues, and accordingly many were defaulted. By 1868, however, it was established that such bonds, as a simple promise to pay a sum certain in money to bearer, must be held fully negotiable. It made no difference that they were issued under seal while the merchant's note was not; the same law should apply.

Instruments called debentures, or debenture bonds, are usually issued for short terms, say, 10 or 15 years. In the U.S., the word debenture signifies that there is no mortgage security, as is usual with the corporate bond. But, to add a speculative element (and, ultimately, to bring about a better capital structure), many debentures—like some bonds—are issued with a conversion privilege. That is, the holder is given an option, on stated terms, to turn his debentures into stock. To add further spice to the transaction, the issuer may establish a sinking fund, and agree to call a given number of debentures by lot, at stated times, for payment. The lottery provisions were all spelled out on the back of the debenture in the *Crouch* case, 1873, which inclined the court to say that such an instrument could not be negotiable; later English cases reached a contrary result. These regulations, and many others lodging powers with a trustee, are now put in the indenture.

Bonds and debentures are almost as precarious to hold as money. That is, if they should be lost or stolen, a subsequent purchaser in good faith would get good title, since they are payable to bearer. Why a practice did not develop to issue such paper payable to "so-and-so or order," thus requiring an indorsement upon transfer, is a matter of surmise. But, for one thing, the long maturities, often 30 years or more in the case of bonds, would make the usual indorsement machinery very cumbersome. For another, there never was any thought that the transferor of a bond should engage to pay the instrument, upon default of the issuer, as the indorser of a negotiable note engages to do. Bonds are not negotiable in that sense; at most the transferor makes certain warranties, of title and so on, as upon the sale of a chattel.

One consequence was the invention of the coupon. It would be highly unsafe, as well as inconvenient, if holders had to bring their bonds and debentures to the issuer each time when collecting interest. But, by writing one coupon for each interest payment, and printing these with the bond, this was made unnecessary. Thus a 30-year bond, for example, is issued with 60 coupons attached, one for each semiannual interest payment, and the holder

may clip his coupons as they mature and put them through his bank for collection with relative safety. Coupons are themselves small promissory notes, payable to bearer, and may be negotiated apart from the bond. The following is a typical wording: The company "will pay to bearer twenty five dollars . . . on the first day of July, A.D. 1900 . . . being six months interest on its first mortgage bond number 4028."

Registration provides a further safeguard. That is, most bonds and debentures are issued payable "to bearer, or, if registered, to the registered holder hereof." This means that a holder of such a bond may send it to the issuer to have it recorded in his name. If fully registered, the issuer will return the bond, minus all coupons, with the name of the sender entered on the back of the bond as owner. It is more usual to register only as to principal, in which case the coupons are not detached. In the U.S., registration renders the bond not negotiable, since it is no longer payable to order or to bearer, though of course it may be sold by being transferred on the issuer's books. Only a small percentage of an issue is ever registered; bonds are quoted at a slight discount when registered.

Share Certificates.—It was not until late in the 19th century that share certificates became a medium for the investment of vast sums of money. At one time, in fact, no certificate at all was issued; the shares were simply inscribed in the owner's name on the books of the company. Transfer was effected, as it still is, by giving a power of attorney (usually with an assignment) to someone to appear before the company or its transfer agent and have the shares entered in the name of the transferee. One reason for this was that the corporation's share obligation was looked on as a chose in action (shares are called *actions* in France), of a different tenor than that of a bond or promissory note, but still a chose in action, to be set up on the liabilities side of the ledger, as is done in modern practice. Thus, while the common law said that a chose in action could not be assigned, it was nevertheless possible to achieve the same result by other means.

However, the shareholder wanted some evidence of his claim. The few specially created corporations of the 17th and 18th centuries, therefore, commenced to issue certificates. When the many privately organized joint-stock companies also started to do so, abuses crept in, and the British parliament passed the Bubble act, forbidding them to issue certificates. Thus, for more than a century, or until 1825 when the act was repealed, there were relatively few share certificates in the market. By the middle of the 19th century, though, the dam had burst; general incorporation statutes were being passed everywhere, and these enabled anyone—on complying with certain simple requirements—to form a corporation and to issue share certificates for sale to the public.

The wording of the certificate has not changed materially. It is a bare recital: "This is to certify that (so-and-so) is the owner of 100 full paid and non-assessable shares of the Common Stock of the General Popcorn Corporation, par value $100, transferable on the books of the company by the holder hereof in person or by duly authorized attorney. . . ." It became the practice for the corporation, as in the case of bonds, to issue elegantly engraved certificates, over the seal of the corporation, "conspicuously put." It may be doubted, though, that this inspired much confidence in the investor, for he has long since come to look first to such things as the company's dividend record, the quality of its management, the price-earnings ratio and the like.

Share certificates are spoken of in financial circles as "equities," bonds and debentures as "debt." This is a useful, but loose, way of speaking. For, as was pointed out in the Rhode Island Trust Co. case (1926), the shareholder "does not own the corporate property"; it is owned, in legal theory, by the corporation. Upon liquidation the shareholder, like the bond or debenture holder, merely has a claim upon the corporate assets, with mortgage bond holders generally being paid first (if the security is adequate), debenture and other unsecured claims next, and common shareholders last. Many corporations also issue preferred stock, which may be given precedence over the common upon liquidation, and usually has priority in the payment of dividends. But common shareholders, unlike other security holders, do have voting rights, though these are coming to have less significance in the large corporation, where shares are widely held.

Negotiability.—The share certificate, in the U.S., never attained negotiability before the courts. The McNeil case (1871), held that they would be treated as quasi-negotiable, where an owner had entrusted his certificates to another, indorsed in blank, but that was on estoppel principles. When equipment trust certificates and security receipts were introduced early in the 20th century, they, too, were denied negotiability: the latter because the promise is to deliver securities, not to pay money, the former because the trustee promises to pay only if and when money is received from the equipment buyer, usually a railroad. When bonds and debentures came to be issued with clauses making the holder's rights subject to the provisions of the indenture, these too were held to be not negotiable; the promise of the issuer, not being an unconditional one, did not fit the pattern of the merchant's note.

The share certificate presented special difficulties. Instead of being regarded as a mere chose in action, shares had come to be looked on fictitiously as tangible property, having a situs at the corporation's office; the certificate was called a muniment of title, like a deed to real estate. The recital on the face of the certificate, providing for transfer on the books of the company, gave some support for the view; but in 1909 the Commissioners on Uniform State Laws proposed the Stock Transfer act to give controlling importance to the market sale of the certificate. The act, with few modifications, was soon adopted throughout the U.S. Under it the good-faith purchaser of a stolen certificate, properly indorsed, obtains full title, and may have the shares transferred into his own name on the company books; nor may a creditor of the registered holder defeat transfer, as once was possible, by serving a writ of attachment upon the issuer. The book transfer recital is recognized only to the extent necessary to protect the issuer; that is, the issuer may still treat the registered holder as share owner: to vote, to receive notices, and as the person to whom dividends may be paid.

Until mid-20th century no comparable legislation was proposed for bonds and similar instruments. In Great Britain, none was necessary, for the court in *Goodwin* v. *Robarts* (1875), assumed jurisdiction to declare new instruments negotiable upon proof of custom. However, in the U.S., a few states amended the Negotiable Instruments Law to include bonds. New York in 1926 passed a more ambitious act, bringing "security receipts," "equipment trust certificates," and "corporate bonds" into the fold. Government issues, such as income or toll-road bonds and special assessment bonds, which also were being held not negotiable, were sometimes covered by the statute authorizing the issue, that is, by a clause providing specially for negotiability. Finally, in 1952, the Commissioners proposed a Uniform Commercial Code which deals comprehensively with investment securities.

The code defined investment securities in broad terms to include any instrument that is commonly dealt in as a medium for investment, is issued in series, and evidences either a share interest or an obligation, provided only, it is "issued in bearer or registered form." Thus, notes and bills payable to "so-and-so or order," which must be transferred by indorsement, are excluded; these are dealt with in a section of the code concerning commercial paper. The line is a somewhat arbitrary one, but it is an important one to draw, for those instruments defined in the code as investment securities may take such form as the issuer may choose to give them and still be negotiable, while commercial paper is held closely to the traditional pattern. Moreover, there are several places where different law applies; defaulted or overdue securities, for example, are given a limited negotiability, contrary to the rule concerning commercial paper.

Liquidity.—During the first half of the 20th century corporate wealth reached vast proportions. Mines, ships, factories, skyscrapers, whole industries in fact, came to be represented by paper instruments, negotiable in form. Thus the buyer may readily put his savings into a bond or debenture of a Delaware corporation, which in turn may own gypsum mines in Canada or a banana plantation in Guatemala. So, too, a person in San

Francisco, by simply indorsing his name on the back of a share certificate, may transfer control of the company to a buyer in New York or London. Many things have contributed to this, but the existence of a securities market is essential; it provides liquidity. Savings would never have been put into paper securities on this scale were it not readily possible to sell them again, at a price.

A market for shares in common stocks (stocks are called shares in England) existed in London throughout the 18th century; it was provided by the brokers of the time who met in coffee houses, in Change alley and elsewhere. The first regular list of prices, for the dozen or more stocks then being traded, appeared in 1714. The present London stock exchange was organized in 1802; the New York stock exchange was organized in 1792, though it did not assume its present name until 1863. Essentially a stock exchange (*q.v.*) is a place where members meet to execute customers' buy and sell orders for listed stocks; sales "at the market" are made to the highest bidder. Thus it is possible in a very few minutes for stocks worth millions of dollars to be sold. The ticker, which has been in use since 1871, reports current sales and prices by wire to all parts of the country.

The exchanges list only those securities which meet their standards. Many issues are not listed, either because the issue is too small, because it is not sufficiently seasoned, because the company does not wish to make the required reports, or for other reasons. These securities, which in the aggregate greatly exceed the value of the listed securities, are traded in by brokers in what is called the over-the-counter market. Also, new issues, which customarily are sold to syndicates of investment bankers on a negotiated basis for later distribution to investors, are traded over-the-counter prior to listing. Since 1926, when the Interstate Commerce commission ordered that equipment trust certificates be sold at competitive bidding, many rail and utility issues have been sold in that way to investment bankers.

Following the stock market crash of 1929, Congress passed the Securities act of 1933 and the Securities Exchange act of 1934 to regulate the securities business; these acts do not apply to securities issued and sold intrastate. Many states have blue-sky laws, so-called because their purpose is to prevent promoters from selling blue sky to the unwary investor. The Securities act, on the other hand, follows the British model, and is designed to safeguard investors, both new and existing, by giving publicity to the important facts concerning each issue before it comes on the market. Bonds and shares today may be purchased with far more information than was the case prior to 1929. *See* also BOND (IN FINANCE); COMMERCIAL PAPER; FINANCE; STOCK (SHARES).

(R. T. S.)

INVESTMENTS: INDIVIDUAL. In the economic sense investment is the productive employment of capital—the direction of savings into uses that fill an economic need. From the point of view of the suppliers of capital, investment is the commitment of present funds for the purpose of deriving a future return in the form of income or capital appreciation. Inherent in the concept of investment (as against speculation) is the emphasis on income and/or growth in value over a period of time (as against short-term trading profits), and the assumption of only that degree of risk that the investor can afford. This requires the selection of investment mediums that are appropriate to the investor's objectives.

Investment Mediums.—Investors have a wide range of general mediums from which to choose. These include: (1) savings types: social security benefits, pensions, annuities, the reserve element in life insurance contracts, savings deposits in commercial and savings banks, accounts in savings and loan associations, and government savings bonds (or savings certificates); (2) securities: federal, state and municipal obligations and corporate securities including bonds (debentures), preferred stocks (preference shares) and common stocks (ordinary or deferred shares) in a variety of industries; (3) real estate held for occupancy and for income, and real estate mortgages; (4) direct investment in a business.

Other classifications of investments are: (1) by investor status: either that of creditor (as through the holding of bonds and annuities) or owner (as through common stocks and real estate); (2) by security: whether the investment (if debt) is a secured (viz., mortgage) or general (viz., bank account) claim; (3) by maturity: whether the principal will mature at a future date (bond or life insurance) or will never mature except through market resale (viz., stocks); (4) by degree of marketability: whether the principal can be recovered through resale (as in a listed stock) or may suffer from a poor market (viz., specialized real estate); (5) by tax status: whether the investment has advantages to investors concerned with high income (tax-free municipal bonds) or seeking capital gains (stocks for appreciation) as against investments producing current taxable income (viz., dividend-paying stocks); (6) by degree of management required: whether constant care and attention is required of the investor (as in a portfolio of corporate securities) as against delegation of investment management to others (viz., life insurance, pensions, trust funds, investment company securities); (7) by degree of risk to income and principal: no risk (U.S. savings bonds or British national savings certificates) versus high risk (speculative stocks); (8) by degree of protection against inflation: no protection (bonds, pensions, bank accounts) versus possible protection (stocks, real estate).

Types of Investment Risk.—Investors must take into account various types of risks associated with different investment mediums and develop an investment program that is appropriate to their resources and particular investment objectives.

Quality Risk.—Investments differ with respect to assurance of income and safety of principal. At the one extreme are government obligations and the savings types; at the other extreme, low-grade common stocks. Corporation securities and real estate include a wide range of quality. The task of selection to minimize risk or to assume only that degree the investor can afford may be undertaken by the investor, or the analysis and selection can be delegated to others. In the investment market the quality of an investment is evidenced by the yield or return that is produced in relation to market price—the higher the quality, the lower the yield. (An exception is found in those "growth" common stocks that pay low dividends in relation to market price and whose appeal is mainly one of possible price appreciation.)

British investors have a similar range of investment opportunities. In the field of government securities, stocks of the central government, counties and municipalities are roughly parallel to U.S. federal and state securities. Many Dominion government issues have been placed in London and have widened the opportunities available to the individual investor. The post office savings banks and trustee savings banks are also popular because interest on small sums is free of tax. National savings certificates and premium savings bonds, both government-sponsored issues, have great appeal to small investors. Building societies also have considerable attraction.

Risk of Price Change.—Cyclical variations occur in interest rates and in corporate profits and dividends that affect the price and income of marketable fixed-income investments as well as equities. The value of high-grade (marketable) bonds rises and falls moderately as interest rates fall and rise. Equity-type securities (common stocks) rise and fall with investors' and traders' estimates of expected earnings and dividends. They reap the benefit of high corporate profits and suffer the most in periods of recession. Purchase of bonds with varying maturities and diversification of stockholdings over various industries will reduce the price risk somewhat; complete avoidance of price risk would require concentration on the savings types of investments. A long-range program of "dollar-cost averaging" whereby the same dollar amount is regularly invested in a diversified selection of stocks, through high and low prices, will minimize the problem of timing their purchase and sale.

Various formula plans that involve an automatic switching to and from defensive securities—high-grade bonds—into more volatile common stocks, depending on the course of stock prices, have been developed to obviate the need for judgment with respect to the course of security prices. Or the task of timing the changes in the investment portfolio may be turned over to others such as trustees, investment counsel or investment companies, which pro-

vide investment management (at a fee). In Great Britain investment counsel, as such, does not exist. All stock brokers will advise without payment; banks and investment advisory firms will review and manage portfolios at a fee.

Money-Rate Risk.—As indicated previously, the prices of marketable securities that return a fixed income (bonds and preferred stocks) rise and fall inversely with interest rates, without necessarily any change in quality. If the investor wishes to avoid such price changes he must concentrate his investments in the savings types whose return is not influenced by any but long-run changes in interest rates, or attempt to select equities whose value is determined mainly by prospective profits.

Purchasing-Power Risk.—The purchasing power of the income and principal of fixed-income investments rises and falls with changes in the general price level or cost of living. Placement of a substantial proportion of the fund in equities—common stocks and real estate—in the hope of obtaining a higher income and an appreciation of monetary value offers the best possibility of an inflation hedge. But such a hedge works only over a considerable period of time. The equities must be purchased at depressed levels (a problem of timing); and all equities are not equally good for inflation protection because industries and companies do not behave alike during any phase of the general business cycle.

Investment Goals and Objectives.—The steps in an investment program are: (1) to determine the investor's goals or objectives in order of their relative priority or importance and to select the general types of mediums that are appropriate; (2) to select the specific investments after careful analysis and with due consideration of the problem of timing.

Individual investors and their needs differ in so many respects that it is impossible to generalize concerning investment objectives or the means by which these may be attained. There are variations in the amount of income available for investment, size of the investor's total resources, age, health, number of dependents, standard of living desired, time and skill available for investment management. And these and other factors change through the years, so that the objectives themselves change. In budgets allowing for modest savings, only the most urgent goals can be attained. As savings accumulate or responsibilities diminish, the objectives can be widened and more risk can be assumed. The following is a suggested list of objectives offered as an illustration of the approach.

Emergency Funds.—The first goal is to provide for unexpected expenditures or interruptions to income. Absolute safety is required, at a sacrifice of investment income. Savings accounts and savings bonds are the mediums used. These provide assurance of principal with modest income, require no management and have satisfactory denominations (U.S. savings bonds may be purchased in units of face value as low as $25). They have no tax advantages and offer no protection against inflation. In Great Britain national savings certificates serve a similar purpose. These certificates are purchased in units of 15 shillings each and interest paid on them is not subject to tax. There is, however, a limitation on the maximum number that may be held by any one person.

Protection Against Death of the Income Producer.—Until a living estate is created, this goal is accomplished for the majority of investors through adequate life insurance. Policies should be selected that provide the greatest protection during the earlier years at the lowest cost; additional and later policies can provide substantial reserves and retirement income. The amount of insurance needed depends on number and age of dependents, income desired for dependents and the size of the estate exclusive of the insurance element. Insurance provides assurance of some income or principal for dependents, freedom from care and management, satisfactory denomination and diversification. It does not provide against inflation save through an increase in the amount of coverage.

Over and above insurance sufficient to provide a minimum income for dependents, funds accumulated for their support can be invested in a variety of mediums. For small investors, savings types and high-grade bonds are indicated. For wealthier investors, who can assume more risk, common stocks and real estate offer opportunities for appreciation and the tax advantages of capital gains, while tax-free municipal bonds are useful in protecting current income against high tax-bracket rates. There are no tax-free municipal bonds in Great Britain but, as noted above, some forms of saving give tax-free income on a restricted scale.

Home Ownership.—This is probably the most substantial single investment goal of most investors. The modern method of amortizing the purchase of a home through a long-term mortgage forces savings into this use and relieves the investor of the problem of accumulating and managing funds for this objective. Once invested in real estate for occupancy, savings are concentrated and are subject to special risks pertaining to such property. An offsetting advantage is the possible increase in value as a protection against inflation.

Education and Other Family Needs.—A variety of objectives fall within this category. In most instances safety of principal and assurance of modest income are important. Accumulations toward this goal should be so planned as to provide definite sums at definite times of need. A program of regular investment in savings bonds is appropriate in many cases. Special insurance protection should be arranged to assure the fulfilment of these goals in the event of the death of the income producer.

Retirement Income.—This is the next investment objective in many cases. Its importance will vary with the age and standards of the investor and his dependents. Annuities, pensions and social security benefits should be combined to provide a minimum risk-free income. In addition, an investment portfolio consisting first of high-grade bonds such as savings bonds, then of carefully selected equities chosen for appreciation as well as soundness may be added as the investor's income and savings increase. The additional sums invested in equities will depend not only on the size of the fund but also on the investment skill of the investor, as well as on his tax requirements and his need for offsetting possible inflation. New York Stock exchange houses make possible the purchase of stocks through regular monthly payments. For many investors equities can best be acquired indirectly through regular purchase of investment company shares (*see* below).

Supplementary Income Before Retirement.—When the above primary goals have been fulfilled, or while the later ones are being concurrently fulfilled, the remainder of the program may involve more risk taking. Safety of principal and future assured income may be given less attention, and current income to supplement salary or business earnings may be stressed. If the investor does not wish to undertake the tasks of selection, timing and management of a fund he may seek the advice of brokers, investment bankers or investment counsel; or he may set up a trust fund or buy investment company shares. The wealthy investor may take advantage of the tax-exempt feature of certain securities, and much of his fund can be invested in higher-risk equities.

Creation of an Estate.—The final goal of some investors, after providing for the above requirements, is the creation of an estate (over and above minimum requirements) for dependents, charities and other beneficiaries. The complex aspects of estate planning may deserve the employment of firms that make a specialty of advice on such problems. The general investment requirements in planning for an eventual estate are: (1) tax relief on current income; (2) substantial liquidity (and insurance) to provide for estate taxes; (3) growth of some of the fund through capital appreciation; and (4) provision against inflation. Practically all of the general mediums of investment listed previously might be involved in such a program.

Selection of Specific Investments.—Selection of the savings types of investments presents few difficulties. Questions of form and convenience predominate. The same is almost true of high-grade bonds, although these must be watched for possible deterioration in quality; also the timing of their purchase (and possible resale) requires some forecast of the trend of interest rates.

The chief difficulties arise in connection with the selection and timing of investment in equity-type investments in those programs in which such investments are appropriate. Investment in real estate for income involves so many special problems that most investors would be advised to avoid it; also, they may already

have a substantial commitment in real estate held for occupancy. Common stocks show the greatest cyclical changes in value, the greatest range in quality and may involve considerable risk. Their exact value is always indefinite. The investor faces the task of appraising general business conditions, the course of stock prices as a whole, the relative outlook for different industries and the earnings, dividends and price performance of individual companies. If he undertakes the task himself he may study business and financial sources, subscribe to investment and statistical services and seek the advice of his broker or bank. Having selected the industries that appear to have the most promise or are most suited to the type of diversification he needs, he will then give attention to the analysis of the individual enterprise, emphasizing its characteristics and peculiar risks, quality of management, financial strength and earning power as revealed by financial statements, prospects for earnings, dividends and price appreciation and the degree of seasoning and marketability of the issue. He must also make a valuation to compare with current market price and be prepared to reappraise his holdings for changes in quality and appropriateness for his particular purposes.

These problems of timing, selection, diversification and continuous management of a portfolio of common stocks are too formidable or too time-consuming for many investors. Consequently, they may turn to one or more of several methods of transferring the responsibility to others. In the United States, professional investment counsel may be retained, at a fee. For those who can afford his advice, the registered investment adviser can fit the program to his client's individual needs, balancing the several factors of income, preservation of capital, appreciation, tax matters and diversification in one co-ordinated program. Other methods of transferring managerial responsibility on a fee basis include the use of investment departments of larger banks, the supervisory services of the larger stock exchange firms and the common trust funds operated by some banks and trust companies. These funds are conservatively invested but, through diversification, superior stability and emphasis on regular income and protection of principal and purchasing power value, have a strong appeal to many investors seeking these requirements.

Two types of institutions provide means for buying into a large portfolio of common stocks by way of the purchase of their shares —fire and casualty insurance companies and investment companies. While established to underwrite risks, the insurance company invests its reserves in a diversified portfolio of securities from which it derives a substantial investment income. Depending on the nature of the portfolio, its shares may offer opportunity for substantial capital appreciation as well as regular income.

Stocks of insurance companies are, however, highly specialized and difficult for the layman to analyze and evaluate. He is likely to turn to the investment company (investment trust) for a more understandable medium for indirect purchase of equities. So important has this institution become that it merits special consideration at this point.

Investment Companies (Investment Trusts.)—Investment companies are financial corporations that pool the funds of their shareholders in a substantial portfolio of securities, so that the investor has a part interest in a variety of individual concerns. Each share of the company's stock represents a fractional interest in the portfolio. The general advantages held out to the investor are: (1) diversification and spreading of risk through holding securities in a cross-section of industries and companies; (2) selection and management of the portfolio by professional experts who through research and constant study adjust the fund continually to changes in market and business conditions; (3) timing of purchases and sales within the portfolio, presumably on the basis of seasoned judgment; (4) convenience through handling for shareholders the details connected with the ownership of corporate securities. These advantages would be especially valuable to the investor who cannot afford investment counsel, cannot obtain diversification with his limited capital and lacks the time and skill to select and manage his own portfolio with successful results.

Most modern investment companies are of the management type, that is, their management has complete discretion over the portfolio held, subject to any charter provisions concerning the general nature of the portfolio, in contrast with the older fixed trusts that could only invest in a given list of securities. The two main classes of investment companies are closed-end companies having a fixed capitalization and whose shares are bought and sold by the investor in the market, and open-end or mutual funds (known in Great Britain as unit trusts) which make a continuous offering of new shares (through distributors) and redeem them on demand; the shares of open-end funds are offered at their net asset value plus, in most cases, a loading fee of 2% to 9% and are redeemed at net asset value, calculated daily. Investment companies may also be classified by type of portfolio securities held as assets. Those owning both bonds and stocks are called balanced funds. Others are common-stock funds holding common stock only, plus a varying amount of cash. Some of the latter are diversified funds; others hold securities in one or more special industries.

Investment companies also differ with respect to their investment purpose. Some are designed primarily to produce income, others for capital appreciation, still others for a combination of both. They differ also in the degree of risk undertaken, ranging from very conservative to frankly speculative funds. The problem of the investor is to select the fund or funds whose objectives and degree of risk taking most closely match his own situation— the ones that will accomplish for him what he would wish to do for himself if he could diversify and manage his own holdings.

Investment companies in the United States are closely regulated by the Securities and Exchange commission, under the federal Investment Company act of 1940, with respect to promotion and sales practices, standards of operation and dissemination of information concerning financial condition and investment policies. Investment trusts in Great Britain are not subject to special legislative control apart from the Companies act of 1948. Unit trusts are subject to board of trade control under the Prevention of Frauds (Investment) act of 1958.

Investment companies (including a few that still operate as trusts rather than as corporations) had their origin in the English and Scottish trusts that were formed as early as 1860 to provide an investment service to individuals either unable or unwilling to select and manage their own security holdings. The early British trusts were mostly of the closed-end type and were conservatively managed. Wide diversification was practised and operating expenses were modest. The early American trusts copied the basic idea of diversification but were less soundly managed. They often indulged in short-term trading; inferior securities were acquired for the portfolio; affiliations with sponsoring banking firms led to abuses. The collapse of the stock market in 1929–32 brought enormous losses and many failures. After a period of confusion in the 1930s, the stronger survivors and new companies enjoyed the renewal of general interest in equities and, by improved performance under federal regulation, grew rapidly and became widely accepted. This is not to say, however, that they have all been well managed and have all produced satisfactory results for their shareholders.

As indicated previously, investment companies do not follow uniform investment policies. They differ with respect to the general types of portfolio securities held, the degree of risk undertaken, the extent of diversification of investment holdings, the extent to which they keep their funds fully invested in various stages of the securities cycle, the relative emphasis placed on income as against capital appreciation and the results obtained for their owners. Most investment companies pay out at least 90% of their net investment income (after expenses) in dividends, and thus avoid taxation on income. Capital gains taxes on any realized but undistributed gains from buying and selling portfolio securities are paid for the shareholders at the source and credit is taken on individual tax returns.

In the selection of an investment company, the investor should first eliminate those whose purposes and record do not coincide with his own aims and objectives, and whose general policies indicate more risk taking than he is prepared to assume. The reputation of the management, the size and growth of the company and

its performance during periods of market weakness should all be examined. Performance is best measured by the cumulative results over a considerable period of time (preferably covering all phases of the business cycle) with respect to dividends and change in net asset value per share as compared with other companies, individual securities and general stock market averages. Other factors to be studied include the expense ratio (per cent of income or of asset value consumed by operating expenses of research and administration), the dividend yield on purchase price and the proportion of dividends representing investment income and capital gains, respectively.

Many open-end investment companies make it possible for the shareholders to reinvest any dividends in new shares without a loading fee and to accumulate new shares by deposit of a regular sum at stated intervals, and thus to obtain the advantages of dollar-cost averaging as the value of the shares rises and falls.

Regulation in the Investor's Interest.—In addition to state blue-sky laws, U.S. federal laws provide protection to investors in a number of respects. The Securities act of 1933 requires corporations that offer new securities in interstate commerce or through the mails to present prospectuses containing a description of the securities and the issuer. Civil and criminal penalties are imposed for fraud and for omission or misstatement of material facts in the prospectus.

The Securities Exchange act of 1934 provides for regulation of securities exchanges and trading to prevent manipulation of prices and abuses of credit in securities transactions. The Trust Indenture act of 1939 requires compliance with standards concerning the indentures that support corporate bond issues and regulates the activities of corporate trustees. The Investment Company act of 1940 (above) and the Investment Advisers act of 1940 regulate investment companies and registered investment counsel firms. The Securities and Exchange commission is the regulatory body under all of these federal statutes.

The legislative position in Great Britain has been referred to above.

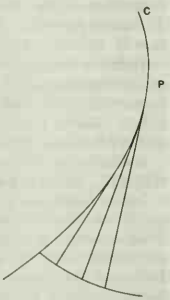
INVISIBLE EXPORTS: *see* EXPORTS: *Invisible Exports.*

INVOLUTE, of a curve C, is a curve that intersects all the tangents of the curve C at right angles. For examples, *see* CURVES, SPECIAL.

To construct an involute of a curve C, use may be made of the so-called string property. Let one end of a piece of string of fixed length be attached to a point P on the curve C and let the string be wrapped along C. Then, as the string is unwrapped, being held taut so that the portion of the string that has been unwrapped is always tangent to C, the locus of the free end of the string is an involute of C. With the same point of attachment P, different involutes of C are obtained by using pieces of string of different lengths. (E. P. L.)



INVOLUTE OF A CURVE C (*see* TEXT)

INVOLUTION, in mathematics, may refer to a transformation of period two of some mathematical system into itself. For example, in projective geometry the projective transformation of period two of a line L into itself may be defined as follows: let I_1 and I_2 denote two distinct points of L. Then for each point P of L there is a unique point, $T(P)$, of L such that P and $T(P)$ separate I_1 and I_2 harmonically (*see* PROJECTIVE GEOMETRY), and this relation between P and $T(P)$ is reciprocal; *i.e.*, $T(T(P)) = P$. As an example from topology, the transformation of period two of the unit 2-sphere (the surface of a solid ball of radius 1) into itself may be defined by sending each point into its antipode. It is significant that the topological space (*see* TOPOLOGY, GENERAL) obtained by identifying each point of the 2-sphere with its image under this transformation is the real projective plane. Observations of this sort have led to the systematic study of periodic transformations (*see* GROUPS, TRANSFORMATION) in topological spaces. (E. DY.)

IO, in Greek mythology, daughter of Inachus, the river-god of Argos and its first king. Under the name of Callithyia, Io was regarded as the first priestess of Hera. Zeus fell in love with her, and, to protect her from the wrath of Hera, changed her into a white heifer; according to Aeschylus in his *Supplices,* the metamorphosis was the work of Hera herself. Hera, having persuaded Zeus to give her the heifer, set Argus Panoptes to watch her. Zeus thereupon sent Hermes, who lulled Argus to sleep and cut off his head or killed him with a stone. But the wrath of Hera still pursued Io. Maddened by a gadfly sent by the goddess, she wandered all over the earth, crossed the Ionian sea (traditionally called after her), swam the strait known on this account as the Bosporus ("ox-ford") and at last reached Egypt, where she was restored to her original form and became the mother of Epaphus. She was thus identified with Isis, and Epaphus with Apis. He was said to have been carried off by order of Hera to Byblos in Syria, where he was found again by Io. This fable connects Io with the Syrian Astarte (*q.v.*). Both legends reflect intercourse with the east and identification of foreign with Greek gods. She was a favourite subject among Greek painters, and many representations are preserved on vases and wall paintings.

IOANNINA (YANNINA; JANINA), a town and *nomos* (department) in northwestern Greece, seat of the governor general of Epirus, a metropolitan bishopric and a divisional headquarters of the Greek army, stands in a broad valley on the western side of a lake, facing the gray limestone mass of Mt. Mitsikeli (5,938 ft.) on the opposite shore. Pop. (1961) 34,997 (town), 155,326 (dept.), including Albanians, Vlachs and Jews. The town is the chief market and commercial centre of Epirus, and is noted for its bazaar and its traditional embroidery, gold and silver work. The lake of Ioannina, the ancient Pambotis, is 6 mi. long and 24 sq.mi. in area, and about 1,500 ft. above sea level. In time of flood it is united with the smaller lake of Lapsista to the north. There are no large affluents, and the only outlets are underground channels or *katavothrai.* The mosque of Aslan Aga, on a promontory in the lake, is now the museum; the island in the lake has five small monasteries of the 13th to 17th centuries.

Prehistoric remains have been found in the neighbourhood, and the island has been connected with the fortress of Euroia described by Procopius (*de Aedif.* iv, 1); but Ioannina is first mentioned by name in ecclesiastical registers of the 9th and 10th centuries. It was stormed by the Norman prince, Bohemund of Tarentum in 1082. It assumed importance in the 13th century with the establishment of the Greek despotate of Epirus. After 1318 it reverted to the Byzantine empire and was made a metropolitanate by Andronicus II; but in 1349 it fell to the Serbs. Subsequently its possession was disputed by Italians, Albanians and Turks, to whom it succumbed in 1430. It remained Turkish until the Balkan War of 1913, although it was famous for its Greek schools. At the close of the 18th century it acquired fame and prosperity as the capital of Ali (*q.v.*), called the Lion of Janina, whose fortress is still to be seen. The town was occupied by the Germans during World War II.

IODINE, a chemical element belonging to the halogen group, was discovered in 1811 by B. Courtois, a manufacturer of saltpetre. He noticed a substance that corroded the copper vats in which he was using a water extract from burned seaweed. He treated the extract with sulfuric acid, and the impurity was isolated as a black powder. When heated, this yielded a violet vapour and condensed in crystalline flakes. It was identified as an element

by J. L. Gay-Lussac in 1815. Iodine at room temperature is a nearly black crystalline solid, vaporizing easily to the deep-violet vapour from whose colour its name is derived (*iodes*, Greek for "violet").

Iodine and its compounds have many uses; *e.g.*, in medicine, the synthesis of organic chemicals, the manufacture of dyes, in analytical chemistry and in the "seeding" of clouds to produce rain. In medicine, iodine is of special importance because it is required in the diet to maintain proper metabolism; if the diet is deficient in iodine, endemic goitre and myxedema result. To prevent iodine deficiency, a small amount of iodine frequently is added to table salt. Iodine also may be used as a topical fungicide and bactericide, *e.g.*, to prepare a body surface for surgery; if improperly used, however, iodine causes inflammation of soft tissues. Iodides also are used as expectorants in chronic bronchitis and bronchial asthma. (*See* also ENDOCRINOLOGY: *Thyroid Gland;* MYXEDEMA; THYROID GLAND, DISEASES OF.)

The most useful artificial isotope of iodine is I^{131}, which has a half life of eight days. It is employed in medicine to measure the functioning of the thyroid gland; to treat thyroid cancer and other diseases; and to locate brain tumours. In investigations of a chemical, biochemical, physiological or similar nature, I^{131} is one of the artificial isotopes used to trace the course of compounds in metabolism, to determine the structure of molecules or for similar purposes. (*See* also RADIOACTIVITY: *Applied Radioactivity.*)

Sources.—Iodine is never found uncombined. It is present in sea water as iodide, 1 part of iodide to 8,000 parts of chloride; it occurs in much animal and vegetable matter, generally in very small amounts, but most abundantly in seaweeds. Appreciable quantities are also found in many natural brines. The largest source of iodine for commercial preparation is the nitrate deposits of Chile, from which saltpetre is prepared, iodine being present as sodium iodate. Iodine is estimated to account for 10^{-5}% of the earth's crust, and to be in 28th place in order of abundance.

For a long time in France and Great Britain and, more recently, in Japan, iodine has been recovered on a commercial scale from seaweed. The stages in the preparation are: drying and burning of the seaweed, leaching of the ash, release of the iodine by chemical reaction and purification. The burning is done in large ovens at as low a temperature as possible to avoid volatilizing sodium iodide. On extracting the ash with water a liquid containing 7–9 g. of combined iodine per litre is obtained. When cooled, considerable sodium sulfate and chloride crystallize, and the remaining liquid is concentrated by evaporation to a content of 30–100 g. of iodine per litre. The addition of sulfuric acid decomposes any sulfite and sulfide. Manganese dioxide added to the acidified liquor releases iodine, which is vaporized and purified by sublimation. In the modern French process, cuprous iodide, obtained by the reaction of cupric sulfate with the concentrated liquors, is the product instead of iodine.

Iodine from Chile nitrate deposits is a by-product of the preparation of Chile saltpetre. The mineral, containing 0.05% to 0.3% of iodine, is treated with hot water, filtered and cooled, precipitating most of the nitrate and leaving a liquor containing 6–12 g. of iodine per litre as sodium iodate. On the addition of a second liquid containing sodium sulfite and bisulfite, the iodate is reduced to iodine:

$$2NaIO_3 + 5NaHSO_3 \rightarrow I_2 + 3NaHSO_4 + 2Na_2SO_4 + H_2O$$

The amount of bisulfite liquor must be carefully controlled since excess will reduce the iodine to iodide. The free iodine is purified by sublimation in retorts.

A more recently developed source of commercial iodine is the brine extracted from oil wells. In California some brines contain 30–60 parts per 1,000,000 of sodium iodide. Two methods have been employed to obtain the iodine. In one process, silver nitrate in 2%–3% solution is added, precipitating the iodine as silver iodide, accompanied by considerable ferric hydroxide. On acidifying with hydrochloric acid, the ferric hydroxide is dissolved, and the addition of scrap iron yields a solution of ferrous iodide and metallic silver that is recovered. The ferrous iodide is decomposed by chlorine, or by sodium dichromate and sulfuric acid, the iodine precipitating in granular form. The precipitated iodine is melted under concentrated sulfuric acid and drawn off in liquid state at as high as 99.8% purity. In a second method, sodium nitrite and sulfuric acid are added to the brine, setting free the iodine in dilute solution. The iodine is concentrated by adsorption on activated charcoal, which, after it has become nearly saturated with iodine, is treated with sodium hydroxide to give a solution containing sodium iodide. The iodide solution is oxidized to iodine by acidified sodium nitrite, chlorine or chromic-sulfuric acid.

Physical Properties.—The atomic weight of iodine is 126.9044, the atomic number 53 and the molecular weight 253.8088. By mid-20th century, isotopes of masses 119–139 had been detected. Except for the natural iodine 127, these isotopes are radioactive and mainly short-lived. The radioactive isotopes are formed in the bombardment of tellurium and iodine with high-velocity particles and in the slow neutron fission of U^{235}. The electron configuration for the unfilled outer orbits (N and O) is: $4s^2$, $4p^6$, $4d^{10}$, $5s^2$, $5p^5$. The electron affinity of the gaseous atom is 3.22 ev. The molecules are normally diatomic but somewhat dissociated at high temperatures. Iodine has a density of 4.93 g. per millilitre at 20° C. The solid melts at 114° C. but has a sufficiently high vapour pressure to sublime readily at lower temperatures. The boiling point of liquid iodine is 183° C. The heat of fusion is 3.650 cal. per mole, the heat of vaporization 9.970 cal. per mole at the boiling point, and the heat of sublimation 14.460 cal. per mole at the melting point. The specific heat of the solid is 0.0513, the liquid 0.0631, the vapour 0.0355 cal. per gram. The entropy of the solid at 25° C. is 27.9 cal. per mole per degree. Iodine dissolves but little in water; at 20° C. the saturated solution contains 0.00133 mole per litre of solution. In most non-aqueous solvents the solubility of iodine is greater; in carbon tetrachloride it is 85 times the solubility in water. The solutions in water and alcohol are brown, in most other liquids, violet.

Chemical Properties.—In compounds the common oxidation states are minus one, plus five and plus seven. Iodine combines readily with most metals and some nonmetals to form iodides. With hydrogen, combination is incomplete since hydrogen iodide is unstable at temperatures sufficiently high for iodine and hydrogen to react. Iodine is reduced to iodide ion by reaction in solutions of hydrogen sulfide, sulfur dioxide and thiosulfate. In all these reactions iodine acts as an oxidizing agent but is the least active of the halogens in this respect. The formation of an iodide is accompanied by the evolution of less heat than is evolved in the formation of the corresponding bromides, chlorides and fluorides. The molal potential of the iodine-iodide electrode in aqueous solution at 25° C. is 0.535 v.

Iodine is the most readily oxidized of the halogens to an oxygen-containing compound. Potassium iodate is more stable than potassium chlorate, and iodine will react with the latter to go to the iodate. Iodine is oxidized to iodic acid by concentrated nitric acid and in basic solution to iodate by such oxidizing agents as chlorine.

Iodine reacts with aqueous ammonia to form nitrogen tri-iodide, $NI_3.NH_3$, which is highly explosive.

Iodine combines with iodides to form polyiodides. With aqueous iodide, the reaction $I_2 + I^- \rightarrow I_3^-$ accounts for the large solubility of iodine in solutions containing soluble iodides. A solution containing 100 g. KI in 100 g. of water dissolves 153 g. of iodine. Iodine at high concentration is poisonous and may cause serious burns; in dilute alcoholic solution (tincture of iodine) or aqueous solution it is used as an antiseptic.

Hydrogen Iodide and Iodide Ion.—Hydrogen iodide is a colourless fuming gas with a sharp odour. It is commonly prepared by the hydrolysis of phosphorus iodide, $PI_3 + 3H_2O \rightarrow 3HI + H_3PO_3$. A solution may be prepared by the reaction of iodine with hydrogen sulfide in solution, $I_2 + H_2S \rightarrow S + 2H^+ + 2I^-$. Hydrogen iodide liquefies at −36° C. and freezes at −51° C. The heat of formation at 18° C. is −5.91 kg.cal. per mole. The compound is not stable thermally, being 22% dissociated to the elements at 450° C. Iodine is liberated from hydrogen iodide by any of the other halogens, by oxygen or by concentrated sulfuric acid.

Like the other hydrogen halides, the gas is very soluble in water, 250 vol. dissolving in 1 vol. of water at 20° C. The aqueous solution, known as hydriodic acid, is a strong acid containing hydrogen and iodide ion. A constant-boiling mixture containing 57% HI by weight, boiling at 127° C., of density 1.70, is formed.

Hydriodic acid may be used to prepare iodides by reaction with metals or their oxides, hydroxides or carbonates, and as a reducing agent in organic chemistry. The iodide ion is a strong reducing agent, the strongest of the halide ions. It is oxidized to iodine by chlorine, bromine, ferric ion, cupric ion and many other oxidizing agents. Because of the reducing ability of the iodide ion, certain metallic iodides cannot be prepared; *e.g.*, cuprous iodide rather than cupric iodide results on the addition of an iodide to a cupric solution. While the iodide ion is colourless, solutions of soluble iodides tend to acquire a brownish tint as a result of oxidation of the iodide to free iodine by atmospheric oxygen. Iodides are generally soluble in water, common exceptions being silver, cuprous, mercurous and lead iodides. Although silver iodide is less soluble in water than silver bromide or chloride, in nonaqueous solvents the iodides are generally the most soluble of the halides. The iodides of metals in general form ionic-type crystals in which the iodide ion has a radius of 2.16 Å.

Potassium iodide, a white crystalline solid, melting at 682° C., of 3.12 specific gravity, is produced commercially to a greater extent than other iodides. It is made by the reaction of ferrous iodide, prepared from iron and iodine, with potassium carbonate, $2FeI_2 + 2K_2CO_3 + \frac{1}{2}O_2 \rightarrow 4KI + Fe_2O_3 + 2CO_2$, or by the reaction of cuprous iodide with potassium carbonate, $2CuI + K_2CO_3 \rightarrow 2KI + CO_2 + Cu_2O$.

Many organic iodides are useful in organic syntheses. Iodine enters organic molecules by direct addition at double bonds and by displacement of hydrogen. The latter reaction occurs less readily than with chlorine or bromine, and the iodine in organic compounds is in general more reactive than the other halogens. When used as a reducing agent in organic chemistry, hydrogen iodide is more effective in the presence of phosphorus, since the liberated iodine forms the more reactive phosphorus iodide.

Oxy Compounds.—Iodine is readily absorbed in alkaline solutions in which some hypoiodite is presumably formed, but since the hypoiodite is unstable, the product is a mixture of iodide and iodate, $3I_2 + 6OH^- \rightarrow 5I^- + IO_3^- + 3H_2O$. This reaction is reversed in acid solution, with iodide and iodate forming iodine. With the addition of an oxidizing agent such as chlorine in alkaline solution, all of the iodine may be oxidized to iodate and solid iodates crystallized from solution. Iodate may also be formed by anodic oxidation of iodide solution and by the reaction of iodine on a chlorate. The iodates are the most stable of the series chlorate, bromate and iodate, and usually the least soluble. Potassium iodate melts at 560° C. and at higher temperatures decomposes to potassium iodide and oxygen. Acid iodates such as $KIO_3.HIO_3$ exist, although no bromate or chlorate of this type is known.

Iodic acid is a moderately strong acid. It may be formed in solution by acidifying solutions of iodates or by the oxidation of iodine by nitric acid, $I_2 + 10HNO_3 \rightarrow 2HIO_3 + 10NO_2 + 4H_2O$. Iodic acid is much more stable than chloric and bromic acids. It is readily dehydrated at 110° C. to give the anhydride, iodine pentoxide, I_2O_5, a white solid that decomposes at about 300° C. without melting. The oxide readily recombines with water to give iodic acid. Treatment of iodic acid with concentrated sulfuric acid yields a different oxide, I_2O_4. The tetroxide is not an acid anhydride; with water it forms iodic acid and hydriodic acid.

The action of excess chlorine in alkaline solution will change iodide or iodate to periodate. A solution of periodic acid may be formed by acidifying a solution of barium periodate with sulfuric acid. Periodic acid is a stronger oxidizing agent in solution than perchloric acid although iodic acid is a weaker oxidizing agent than chloric acid. Periodic acid differs from perchloric acid also in that it is not always monobasic. Thus, not only such metaperiodates as KIO_4 and $AgIO_3$ but also mesoperiodates of which Ag_3IO_5 is an example, and paraperiodates such as Ag_5IO_6, are known. The existence of these salts may be attributed to the large size of the central iodine atom, about which a larger number of oxygen atoms may be co-ordinated. Most periodates are but sparingly soluble; this property as well as the proportion of acid and base are factors in determining which of the possible periodates forms in the reaction of periodic acid with a given base or metal ion. In commercial preparation, the reaction of sodium iodate with chlorine in alkaline solution yields the disodium meso salt, $2Na^+ + IO_3^- + 3OH^- + Cl_2 \rightarrow Na_2HIO_5 + 2Cl^- + H_2O$. Periodic acid, itself, crystallizes from solution as H_5IO_6, which may be dehydrated to HIO_4 by heating to 100° C. in a vacuum. Attempts to prepare the anhydride of periodic acid, I_2O_7, have not succeeded as oxygen is lost in further dehydration of the acid.

Analytical Chemistry.—Iodine is detected by the violet colour of its vapour or of its solution in carbon disulfide or carbon tetrachloride. In aqueous solution minute amounts of iodine in the presence of starch give a bright blue colour. None of the other halogens gives these colours. If present as iodide, the iodine is first set free by the action of an oxidizing agent such as chlorine water; or if present as iodate or periodate, by reduction with sulfurous acid. Iodine is determined gravimetrically by precipitation as yellow silver iodide, which is insoluble in nitric acid and ammonia. Volumetrically, iodine is titrated with a standardized solution of sodium thiosulfate, usually in the presence of starch as indicator. The iodine is consumed by reaction, $I_2 + 2S_2O_3^{2-} \rightarrow 2I^- + S_4O_6^{2-}$, and at the end point the blue colour disappears, leaving a colourless solution.

The reaction of iodine with thiosulfate is of great importance in analytical chemistry. It is employed in the determination of many substances that have oxidizing properties. For example, dichromate may be determined quantitatively by first allowing the dichromate solution to react with excess potassium iodide solution, $Cr_2O_7^{2-} + 6I^- + 14H^+ \rightarrow 3I_2 + 2Cr^{3+} + 7H_2O$, and then titrating the liberated iodine with standard thiosulfate solution. Even substances with weak oxidizing powers may be determined in this way; *e.g.*, copper, by the reaction $2Cu^{2+} + 4I^- \rightarrow 2CuI + I_2$. Some other determinations that may be made in this way are of chlorine, bromine, iodate, persulfate, hydrogen peroxide, nitrite, arsenate, ferricyanide, permanganate, manganese dioxide and ferric iron.

Many reducing agents may be titrated directly with a standard solution of iodine in potassium iodide using the starch indicator. In these titrations the iodine is reduced to colourless iodide; *e.g.*, with arsenite, $HAsO_3^{2-} + I_3^- + H_2O \rightarrow AsO_4^{3-} + 3I^- + 3H^+$. Titrations of sulfite, sulfide, thiosulfate, ferrocyanide, stannous and antimonous ion may be made in this way. Determination of reducing and oxidizing agents in which iodine or iodide is employed are known respectively as iodimetric and iodometric determinations.

Iodine compounds are employed in other analytical procedures. A solution of mercuric iodide in excess potassium iodide, containing the complex ion HgI_4^{2-}, known as Nessler's reagent, is used in the determination of ammonia, with which it forms a yellow precipitate, $Hg_2NI.H_2O$. Small amounts of water in organic liquids are determined by titration with a pyridine solution containing iodine, sulfur dioxide and methyl alcohol. This solution is known as the Karl Fischer reagent. Potassium iodate and biiodate, $KIO_3.HIO_3$, are of importance as oxidizing agents in analytical chemistry. Potassium periodate is a valuable oxidizing agent in the determination of manganese. It will oxidize manganous ion to permanganate ion quantitatively in acid solution, the permanganate being determined colorimetrically.

The content of unsaturated compounds in oils is determined by measurement of the quantity of iodide absorbed. The per cent of its own weight of iodine that a sample of oil will absorb under certain specified conditions is known as the iodine number. Concentrated hydriodic acid is used in the Zeisel method for determination of methoxy groups.

Soluble iodides are employed in detection and estimation of alkaloids with which they form precipitates.

IODOFORM, formerly valued as an antiseptic, although now no longer widely used in medicine, was discovered by G. S. Sérullas in 1822. It can be prepared by the action of iodine and an aqueous base on ethyl alcohol, acetaldehyde, acetone, isopropyl alcohol or almost any other compound containing either the CH_3-CO-C or the CH_3-CHOH-C groups. For this reason, the "iodoform test," which consists in the formation of iodoform by the procedure described, is commonly employed in the chemical laboratory for establishing the presence of the stated groups.

Iodoform, CHI_3, crystallizes in yellow hexagonal plates melting at 119°–120° C., and is readily soluble in alcohol or ether but is only very slightly soluble in water. It has a characteristic odour and is volatile in steam.

IOLITE: *see* CORDIERITE.

IONA, an island of the Inner Hebrides, Argyllshire, Scot., lies 6½ mi. S. by W. of Staffa and 1½ mi. W. of the Ross of Mull, from which it is separated by the shallow Sound of Iona. Pop. (1961) 130. Iona is low-lying; the highest eminence is Dun Bhuirg which rises to a height of only 332 ft. above sea level. The island covers 2,264 ac. and is 3 mi. long and 1½ mi. wide. At no time has it had more than a handful of permanent residents. Most of the island is rough grazing land but there is some permanent pasture and a few crops are grown. Sheep and cattle are reared. The principal occupations of the people are small-scale farming and the tourist trade. For many centuries water supplies were drawn from private wells but a communal water scheme was inaugurated by Argyll county council in 1960.

Archaeology.—The first part of the island to be inhabited was the top of Dun Bhuirg which was fortified sometime during the Roman period by natives of western Scotland.

Excavations in 1958 and 1959 have revealed the outline of the original monastery, founded by St. Columba in 563. The site of Columba's living cell, on a mound known as Tor Abb, traces of the round cells of the brethren and of two much larger buildings have been found. A layer of charcoal and other burnt material covering these remains date from the Norse invasions of the 8th or 9th century when the wooden buildings were burned down. The monastery was probably rebuilt, of stone, in the second half of the 9th century. Most of it is beneath the present abbey though part of a small stone building, possibly the church, has been found in the cloister garth. The High Crosses (St. Martin's, which is also known as the Iona cross, the stump of St. Matthew's, fragments of St. John's and pieces of another) appear to date from this period as also does the Relig Odhrain (St. Oran's cemetery), the royal burial ground with a small chapel.

A square precinct surrounded the Benedictine abbey and its cruciform church of St. Mary's, built in the second half of the 12th century. This abbey was paved and huge stone field drains kept it dry. In 1959 a roadway 7 ft. wide, made of red granite boulders from Mull, was uncovered. It led from the abbey, across the Relig Odhrain, past the nunnery to a landing place at Martyrs' bay and was the *Straid nam marbh* or Street of the Dead. It is thought to have been built between the 13th and the 16th centuries.

History.—The name of Iona, probably a corruption of Ioua, has long been accepted, though other old Gaelic spellings are simply I (pronounced "ee") Hy, Eo, Y, etc. I is found in I-Chaluim-Chille (Icolmkill, the Island-of-Columba-of-the-Church). Readily accessible from Ireland by sea, it formed an integral part of the dominions of the Gaelic-speaking kings of Scottish Dalriada. About 563 Columba, who was a kinsman of the royal house, came over from Ireland and with 12 followers settled on Iona. There he built a monastery and began to evangelize the Picts. He established the Celtic Church (*q.v.*) there and sent missionaries through mainland and insular Scotland. In 597 he died and was buried on the island. (*See* COLUMBA, SAINT.)

Columba's evangelizing work was continued by his successors who extended their sphere of influence to England and the European continent. According to Bede, in the 7th century Oswald and Oswui, sons of King Aethelfrith of Northumbria, took refuge in Iona where they learned the Gaelic speech and adopted the religion of the monastery. In 795 the first Norse invasion took place, to be followed by others in 802, 805, 840 and 986. The wooden monastery was burned down, and during the last raid the abbot and 15 monks were murdered. Iona's growing insecurity led to the transfer in 849 of the relics of St. Columba to the safety of Kells in Ireland. When Kenneth MacAlpin (*q.v.*), a follower of St. Columba, died in *c.* 860 he was buried on the island, probably because it was traditionally the burial place of the Dalriadic kings. The Relig Odhrain is thought to have been founded then as a separate burial place for Scottish kings. Its chapel was probably rebuilt by St. Margaret (d. 1093), wife of Malcolm Canmore, who restored the monastery, though the Celtic Church had by then given place to the Church of Rome.

The Norsemen, who had become Christians, included Iona in their diocese of Man and the Isles in the 11th century and in 1154 they put the see under the archbishop of Trondheim. This supremacy lasted until 1266 when the Hebrides were ceded to Scotland. In 1203 Reginald, lord of the isles, the son of a semi-independent Hebridean chief, Somerled, established a Benedictine monastery and nunnery on Iona. Somerled's descendants, the MacDonald lords of the isles, granted various estates in Tiree, Ardnamurchan, mid-Argyll, Kintyre and Islay for the upkeep of the abbey. With the forfeiture of the last MacDonald lord in 1493 the former vassal clans became independent and lawless, and during periods of unrest diverted much of the abbey's revenues to their own private purposes. Successive proprietors of Iona were the MacLeans and the Campbells.

In 1899 George Campbell, 8th duke of Argyll, transferred to trustees of the Church of Scotland the old ecclesiastical building. Before doing so he had carried out various improvements at his own expense. The trustees, mainly laymen, rebuilt the abbey church and it was opened in June 1912 for public worship for the first time for more than three centuries. In making over the abbey buildings the duke expressed the wish that they should be made available to all Christians, but differences in religious practices have so far rendered this impracticable.

The Iona Community.—In 1938 George MacLeod, parish minister of Govan (part of Glasgow), sought to infuse a new vitality into Christianity. He was convinced that the wide gap between actual life and theoretic religion should be closed and that, as in the Celtic Church of St. Columba, the spiritual and the material should be intertwined. The still pitiful condition of many of the ancient buildings on Iona offered George MacLeod and his seven comrades an opportunity for showing something of the spirit that had impelled Columba and his 12 missioners, more than 1,300 years earlier, to leave their native Scotia (Ireland) and carry the gospel to far-off lands. With the full approval of the Church of Scotland they began their work of restoring the ruinous buildings, and in 1959 when the cloisters, the sanctuary and the sacristy were finished the abbey was consecrated.

The Iona community is a missionary group of clergy and laymen within the Church of Scotland. In the early 1960s it had more than 6,000 full and associate members. Most of the year is spent working on the mainland, chiefly in industrial parishes, and abroad. The primary conditions of membership, however, entail residence for part of the summer on Iona and personal participation in the devotions of the community and in the physical work of restoration. The members adhere to a community "rule" of prayer and Bible study rather than to any particular ritual., Christian groups and individuals of all denominations, and young people, chiefly from industrial towns, visit Iona every summer for recreation of body, mind and spirit.

ION EXCHANGE, a process in which ions (electrically charged atoms or groups of atoms) attached to or incorporated within the molecular structure of insoluble substances, called ion

exchangers, exchange with ions present in a surrounding solution. The process has also been called base exchange and exchange adsorption. Ion exchangers are essentially insoluble acids or bases, the salts of which are also insoluble. Ion exchangers may undergo exchange either with positively charged ions (cations) or negatively charged ions (anions). In the former case the process is referred to as cation exchange and in the latter as anion exchange. (*See* also ADSORPTION; SOLUTIONS.)

Numerous substances, of both natural and synthetic origin, possess ion exchanging properties. These include proteins, synthetic resins, cellulose, bone, living cells, silicate minerals and soils. For commercial and laboratory uses the inorganic ion exchangers include the natural zeolites, glauconite and greensand, and synthetic zeolites such as the sodium aluminosilicates (*see* ZEOLITE). Inorganic ion exchangers have been prepared from insoluble salts, heteropoly acids, and hydrous oxides. These include compounds such as zirconium and titanium phosphates, zirconium and tin oxides, ammonium molybdophosphate, and many other insoluble compounds possessing ion exchanging properties. Inorganic ion exchangers are of special interest because they are more stable than organic ion exchangers under certain conditions, such as high temperatures and ionizing radiation. The organic ion exchangers include the sulfonated coals (*see* SULFONIC ACIDS) and, most important of all, synthetic resins (*see* RESINS: *Synthetic Resins*). The synthetic resins are plastics which may be chemically modified to impart or enhance their ion exchanging properties.

Ion exchangers can be prepared in a variety of geometric shapes, forms and internal structures. Among the most important forms are sheets, or membranes, which are widely used for electrochemical purposes (*see* ELECTROCHEMISTRY). The structure of the synthetic resins can be modified to enhance or impart desired physical or chemical properties. These include the chelating resins, into which are incorporated chemical groupings possessing a preferential affinity for a given ion or group of ions. Another type of ion exchange resin incorporates materials, such as *p*-terphenyl, which scintillate when exposed to ionizing radiation. These scintillating resins permit the direct determination of the concentration of absorbed radioactive ions. (*See* NUCLEAR INSTRUMENTS: *Scintillation Counters.*) Paper can be impregnated with ion exchanging substances for use in paper chromatography (*see* CHROMATOGRAPHY: *Paper Chromatography*). A related development involves liquid ion exchangers in which ion exchange takes place between two immiscible liquid phases. (*See* LIQUID STATE.) These liquid ion exchangers are commercially available and are used for separations of materials, especially by continuous countercurrent operations.

For information about the use of ion exchangers in water softening and many other processes *see* below, *Applications.*

Historical Development.—In 1850, in separate publications by the English agriculturist Harry Stephen Meysey Thompson and the English chemist John Thomas Way, the phenomenon of ion exchange occurring in soils was recognized and systematically investigated.

In the early 19th century it was known that plants required nitrogen for growth and, further, that the ammonia given off by manure heaps was taken up by the soil. Sulfuric acid or sulfate salts were often used to fix the ammonia by the formation of ammonium sulfate. In 1845 Thompson, in collaboration with Joseph Spence, a chemist and druggist, conducted a series of experiments in order to test the extent to which soils could fix ammonia and "to ascertain whether it also extended to the sulfate, as if not, the use of sulfuric acid as a fixer, though preventing the escape of ammonia in a volatile form, would have been objectionable from its forming a highly soluble salt that would readily be washed down into the subsoil or carried off in drains." In one experiment a sample of soil forming a six-inch-high column was placed in a glass percolator. The soil had been mixed previously with a known quantity of ammonium sulfate. When water was passed through the column it was found to the experimenters' "complete surprise" that most of the ammonia was retained by the soil, that it could not be removed by leaching with water and that "this process was in some way connected with the presence of lime in the soil, as the sulfuric acid was washed out in combination with lime." Though Thompson was actually unaware of the correct explanation, the ammonium ion had exchanged with the calcium ion present in the soil, while the negatively charged sulfate ion was unabsorbed. The process can be written as:

$$Ca \cdot Soil + (NH_4)_2SO_4 \rightleftarrows 2NH_4 \cdot Soil + CaSO_4$$

In 1848 Thompson communicated a brief outline of his results to Way, who had recently been appointed consulting chemist to the Royal Agricultural Society of England. Way conducted a carefully designed series of experiments to elucidate the reaction of soils with metal ions. One of the most important conclusions Way drew from his investigations was that the cation exchange reaction was chemical in nature. He also pointed out that the displacing ability of individual cations from inorganic cation exchanging silicates was different but followed a reproducible order.

Way also demonstrated that the inorganic minerals in soil possessed marked exchanging properties (*see* SOIL: *Chemical Properties of Soils*). In fact he prepared the first synthetic cation exchangers of the aluminosilicate type having the approximate formula for the sodium form of $Na^+AlSi_3O_8$ in which the Na^+ is exchangeable. The first successful commercial applications of ion exchange were initiated in 1905 by Robert Gans, a German chemist, who obtained several patents for the preparation of synthetic hydrated aluminosilicates capable of softening water.

A disadvantage of cation exchangers of the inorganic or siliceous type is that their use is restricted to a narrow pH range near neutrality, because they eventually disintegrate in acid or highly basic solutions. Consequently their use is confined principally to water softening. In 1930 it was found that the sulfonation of various types of coal converted them to cation exchangers which could function even in highly acid mediums; this made it practicable to exchange metal ions for hydrogen ions. The predominating exchanging group in the sulfonated coals was a sulfonic acid group ($-SO_3H$) in which the hydrogen is exchangeable.

In 1935 I. B. A. Adams and E. L. Holmes discovered the ion exchanging properties of synthetic resins. Both men were employed as chemists in the British government research laboratory at Teddington, Eng. Their joint efforts led to the synthesis of phenolic resins, resembling Bakelite, capable of undergoing cation exchange; and resins capable of anion exchange. The latter resins were prepared from condensation of polyamines with formaldehyde. Although these first resins were not very useful in themselves, their synthesis meant that chemists could now synthesize ion exchange resins with properties nearly as desired. In 1942 G. F. D'Alelio showed that efficient resins could be made by incorporating individual chemical groups possessing exchanging properties into preformed synthetic plastics which in themselves had no exchanging properties but were exceedingly stable.

These discoveries accelerated the introduction of ion exchange processes into numerous technological and laboratory operations. Some of the more important developments were: (1) U.S. chemists of the Manhattan Project (atomic bomb research program) demonstrated that by simple and rapid ion exchange processes plutonium could be separated from uranium and fission products, and individual members of the chemical group known as the rare earths (*q.v.*) could be isolated. These findings led to the remarkably successful use of ion exchange to resolve highly complex mixtures of nucleic acids, amino acids, isotopes and several new elements. (2) In 1949 ion exchange resins were first prepared in the form of sheets, or membranes. While the use of membranes which permitted only ions of one sign to pass through had been known for years, the commercial availability of more stable and effective membranes made from the physically and chemically tough ion exchange resins greatly expanded the potential applications of a membrane system. In use, these membrane systems employ an electrical current to induce selective transport of ions, as explained below. (3) In 1953 there was introduced a process utilizing ion exchangers to separate ionized substances from nonionized or slightly ionized substances in water solution. This process, called ion exclusion, made use of the fact that nonionized substances such as alcohols and sugars are free to diffuse unhindered into the water

phase of the ion exchange resin while ions are excluded because of their electrical charges. Inasmuch as the nonionized materials retained by the resin can be removed by additional water washes, the technique of ion exclusion made possible the deionization and separation of many products without the use of heat, electricity or chemical regenerants. (4) In the 1950s U.S. chemists at the Oak Ridge National Laboratory discovered that exchangers (especially anion exchangers) can retain ions with an amazing tenacity from solutions in which the supporting or foreign electrolyte is present in concentrations up to 12 molal and higher and which form complex ions with the absorbed ion. Retention of the ions varies enormously with the concentration of the supporting electrolyte, so that the removal and separation of the ions can be accomplished very efficiently simply by passing different concentrations of the supporting electrolyte or pure water through a column of the ion exchanger (*see* below, *Techniques*).

Ion Exchange Resins.—An ion exchanging resin consists of a polymeric organic network or backbone and ionized or functional groups which undergo exchange. A very effective organic network is formed by the polymerization of styrene in the presence of varying amounts of divinylbenzene, which serves to crosslink the long chains of styrene into a three-dimensional fish-net type of structure. Functional groups are introduced subsequently into the polystyrene or, in the case of other ion exchangers, may be part of the monomer. Common functional groups in the case of cation exchangers consist of acid groups such as carboxylic groups (R—COOH), sulfonic groups (R—SO_3H) and phenolic groups (R—OH); while anion exchangers contain basic amine groups such as quaternary ammonium groups (R—R'_3N^+—OH^-) and primary, secondary and tertiary amines (R—NH_2, R—R'NH, R—R'_2N), where R represents the organic network and R′ represents organic radicals such as the methyl group ($-CH_3$). In a given resin the R′ groups may be the same or different. Resins in which all the functional groups are identical are called monofunctional. Schematic diagrams of a crosslinked polystyrene strong acid and strong base ion exchanger are shown in fig. 1. These ion exchangers are prepared in the form of spheres or beads varying from less than 0.04 mm. to 1 mm. in diameter. Larger-size beads tend to crack during the manufacturing process. The commonest particle diameters used for water treatment are the range from 0.84 to 0.297 mm., but for certain difficult separations smaller sizes are used.

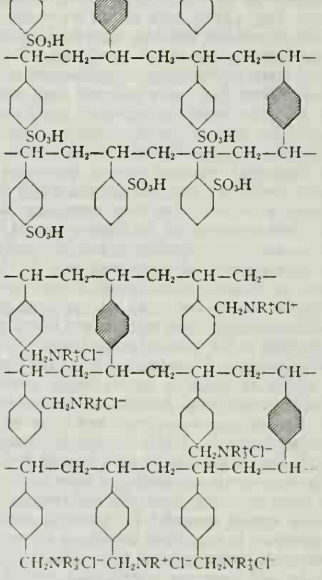

FIG. 1.—HYPOTHETICAL SCHEMATIC DIAGRAM OF A SULFONATED POLYSTYRENE CATION EXCHANGE RESIN CROSSLINKED BY DIVINYLBENZENE (TOP DIAGRAM) AND A STRONGLY BASIC QUATERNARY AMMONIUM ANION EXCHANGE RESIN (BOTTOM). THE CROSSHATCHED BENZENE RINGS SHOW THE DIVINYLBENZENE CROSSLINKAGE POINTS

Ion exchange resins of the type shown in fig. 1 are markedly resistant to chemical and physical attrition and are insoluble in all the common organic and inorganic solvents, including mineral acids and bases. High concentrations of oxidizing agents such as nitric acid can have deleterious effects by attacking the resins at a vulnerable point—the crosslinks. The salt forms of the cation exchange resins in contact with solutions can withstand temperatures up to about 140° C.; those of the anion exchange resins are stable up to about 90° C.

When immersed in water the ion exchange resins take up water and swell. The extent of swelling depends on the degree of crosslinkage—a quantity expressed by the percentage of divinylbenzene (DVB) used to prepare the resin. Thus a 10% DVB resin—the most commonly used—is made up of beads synthesized by the use of 90% by weight of styrene and 10% by weight of divinylbenzene. The extent to which a resin swells or shrinks depends on the salt concentration of the surrounding solution—the higher the concentration the less the swelling.

Ion exchange resins must have a crosslinked structure because the ionizable groups enhance the solubility and thus promote swelling. Too few crosslinks result in excessive swelling and reduced selectivity toward ions; while too many crosslinks so tighten the structure that the rate of the ion exchange reaction is too slow, since it depends on ionic diffusion. In practice a compromise must be effected in order to obtain a useful exchange resin. However, in special applications the ability to utilize resins of different crosslinkage is highly useful and sometimes indispensable. For example, when very large ions are to be taken up it is often desirable to use a low crosslinked resin so as to facilitate the entrance of the large ions into the "pores" of the resin.

Special resins are synthesized so as to contain functional groupings which have a specific or marked affinity for certain ions. Other special resins include types which undergo oxidation-reduction reactions. Instead of exchanging ions, these electron exchange polymers exchange electrons.

Ion exchangers are available which contain both acidic and basic groups. Such materials, containing the functional groupings attached to the organic matrix, are to be contrasted with a more widely used type of amphoteric resin called snake-cage polyelectrolytes. The latter are conventional cation or anion exchange resins in which are produced linear, (*i.e.*, non-crosslinked) polyions of opposite charge to the fixed groups. The linear chains of the counter-polyions are intertwined, in snakelike fashion, with the resin matrix so that they cannot escape or be displaced by other counter-ions. These resins are used for the so-called ion retardation separations mentioned later.

Extremely porous resins are prepared by a process in which the conventional polymerization technique is carried out in the presence of a substance that is a good solvent for the monomer but a poor swelling agent for the polymer. As a result, the solvent is squeezed out and beads are obtained with large pores. These macroreticular ion exchange resins are particularly useful for certain applications since the pore structure does not collapse on drying. The rates of acid-catalyzed reactions are much faster with macroreticular resins than with the conventional types.

In the table a summary is given of some of the major types of available ion exchange resins, together with other pertinent information.

When the acid or hydrogen form of a cation exchanger is neutralized with sodium hydroxide, a plot of the cubic centimetres of base added against the pH yields a titration curve. Such curves are an important and convenient method of characterizing ion exchange resins, because they give information on the number of kinds of functional groups present, their acid or base strength

Principal Types of Ion Exchange Resins Available Commercially

Resin	Total capacity (Milliequivalents 1 g.)	Total capacity (Milliequivalents 1 c.c.)
Cation exchangers		
Strong acid (sulfonated polystyrene)	4.2	2.2
Carboxylic	4–10	1–4
Phenolic methylene sulfonic	1.3–2.5	0.5–1
Sulfonated coal	1.6	0.6
Aluminum silicate	1	—
Anion exchangers		
Strong base	2.3–2.5	1.0
Weak base	6–10	2–2.5

and the capacity of the resin. The behaviour of a carboxylic acid resin of the type (R—COOH) closely parallels that of moderately weak acetic acid (CH_3—COOH), while the behaviour of monofunctional sulfonic acid resins resembles that of the strongly acid hydrochloric acid. On the other hand, the quaternary-ammonium-type anion exchange resins are nearly as basic as sodium hydroxide.

Techniques.—Contact between a solution and an ion exchanger involves either a batch or column process. In the batch process the resin is simply mixed with solution and agitated continuously or intermittently until equilibrium is reached—a period of a few minutes or several days depending on the resin and type of ions being exchanged. After equilibration the resin is removed by filtration. Batch techniques are infrequently employed for industrial purposes, but are often used in the laboratory for fundamental studies of the mechanism of ion exchange reactions.

Column methods generally involve fixed-bed operation, which refers to the use of a packed column of resin through which is passed the feed or regenerant solution. The resin is supported on a porous support while solution flows through by gravity or under pressure. The solutions are usually passed down through the resin, though up-flow operation is not uncommonly employed, especially when it is desired to remove suspended particles from the resin bed during regeneration.

A fixed-bed cycle generally consists of the following steps: (1) saturation of the bed with solution until the desired or undesired ions break through to a predetermined level; (2) removal or elution of the retained ions by regenerant solutions; (3) rinsing of the bed free of regenerant so that the cycle can be repeated. Between cycles the bed may be backwashed by up-flow passage of water.

A less used but potentially important variation of column operation is the so-called moving bed or continuous countercurrent system. Here both the resin and solution are made to flow through the system.

An effective method for separating difficultly resolvable mixtures on the laboratory scale is by the technique of chromatographic elution. The ions to be separated are placed on the top of the resin bed and subsequently eluted stepwise with a solution containing ions capable of displacing the absorbed ions. The displaced ions move down the column as bands or zones at different velocities. If the column is long enough the bands may completely separate from one another, and the substance confined to each band is recovered in the outgoing solution, called the effluent.

Most applications of ion exchange involve column operation, because of the completeness of separation which can be obtained and the ease with which automatic instrumentation can be employed. Column techniques correspond to the use of a large number of batch operations in series, an analogy closely akin to fractional distillation processes.

Mechanism of Ion Exchange Reactions.—The equilibrium between monovalent exchanging ions, A^+ and B^+, for a cation exchanger can be written as a simple chemical reaction:

$$A^+ + BR \rightleftarrows B^+ + AR$$

where R represents the immobile resin anion with an assumed charge of −1. Ion exchange reactions in dilute solutions exhibit (1) exchange of equivalent amounts of ions; and (2) preferential uptake by the exchanger of one ion over another. These properties are defined by the selectivity quotient, Q:

$$Q = \frac{[AR][B^+]}{[BR][A^+]}$$

where [AR/BR] is the molar ratio of the ions A^+ and B^+ in the resin phase in equilibrium with concentrations $[A^+]$ and $[B^+]$ in the solution phase. When $Q=1$ the resin shows no preference for A^+ over B^+. For easy separation it is important that Q be as far as possible from unity. When $Q>1$ then the resin shows preference for A^+ over B^+ and vice versa.

The selectivity quotient is not constant under varying conditions; it depends, for example, on the nature of the resin, the total concentration of the solution and the ratio of ions in the resin phase, and the nature of the ions. Inasmuch as the efficiency and hence the design of a column operation depend on the values of Q, it is apparent that the determination of Q is important. The greater Q differs from unity, then the shorter can be the column, the faster the flow rate and the sharper the separations.

In general terms and for dilute solutions, the affinity of an ion for an ion exchanger is governed largely by electrostatic forces and depends mainly on two factors—ionic charge and ionic size. Ions of higher charge are generally held more tightly, as in the series $Th^{4+} > La^{3+} > Sr^{2+} > Na^+$. For ions of the same charge the ion with the smallest radius in solution is held the strongest. Thus for the alkali metals the order is: $Cs^+ > Rb^+ > K^+ > Na^+$; which reflects the fact that while Cs^+ has the largest crystal radius its hydrated radius is the smallest. That the hydrated radius is the important parameter is shown by the fact that in alcoholic solution where the ions become dehydrated, the affinity of the alkali metal ions for the ion exchanger is in the reverse order. The affinity of a cation exchanger for H^+ depends on the acid strength of the functional group.

A related and much-used quantity for evaluating separability is the distribution coefficient K_d, defined for a given ion in any ion exchange system, as for A^+, for example:

$$K_d^A = \frac{[AR]}{[A]} = \frac{\text{concentration } A^+ \text{ per unit weight resin}}{\text{concentration of } A^+ \text{ per c.c. of solution}}$$

The ratio $K_d^A/K_d^B = Q$ is called a separation factor.

Inasmuch as the functional groups of a resin are fixed, it is possible to formulate ion exchange reactions as a Donnan equilibrium (unequal concentration of diffusible ions in the solution relative to fraction bound by the polyelectrolyte). Consequently, for a reaction involving H^+ and Na^+:

$$Na^+ + HR \rightleftarrows NaR + H^+$$

and omitting activity coefficients (*see* SOLUTIONS: *Solutions of Electrolytes*), the equilibrium quotient, K, is

$$K = \frac{[NaR][H^+]}{[HR][Na^+]}$$

This equation is identical in form with one based on the law of mass action.

When the resin phase is treated as an ordinary aqueous solution, and the standard state is taken to be the same in both phases, then the value of K becomes unity when both phases are dilute. However, in the ordinary 10% DVB resin the internal concentration is about 6 molal; hence it is necessary to insert activity coefficients into the equation to take into account the marked effects of concentration changes on equilibrium. When resins of very low crosslink are used, the internal resin phase becomes more dilute; *i.e.*, the resin takes up more water. This serves to reduce the selectivity of the resin for one ion over another because the differences in activity become less.

When ions of unequal valences are exchanging, such as Ca^{2+} and Na^+, the ion exchange reaction is

$$Ca^{2+} + 2NaR \rightleftarrows CaR_2 + 2Na^+$$

and

$$K = \frac{[CaR_2][Na^+]^2}{[Ca^{2+}][NaR]^2} = Q\left[\frac{Na^+}{NaR}\right]$$

From the definition of Q it is found that the selectivity of the resin for Ca^{2+} relative to Na^+ is given by the expression

$$Q(Ca/Na) = \frac{K[NaR]}{[Na^+]}$$

When the concentration of Ca^{2+} is very small relative to Na^+, then [NaR] remains nearly constant; and it is seen that the selectivity of the resin for the divalent cation is inversely proportional to the sodium concentration in solution. Thus in water softening, where a dilute solution of Ca^{2+} and Na^+ salts is dealt with, the resin is very efficient in removing the Ca^{2+}. However, in regeneration the use of a strong solution of sodium chloride is effective in eluting calcium. The use of greater concentrations of the ion of lower valence tends to reduce its relative affinity for the resin.

The resin phase must maintain electrical neutrality at all times. Because of the presence of a preponderance of nondiffusible "resinate" ions (R^- in the case of a cation exchange, and R^+ in the case of anion exchange) the penetration of ions of the same charge into the resin phase is hindered—a manifestation of the Donnan effect. Consider the case of the hydrogen form of a cation exchanger immersed in a solution of hydrochloric acid. In dilute solutions the concentration of Cl^- in the resin phases is nearly nil. However, as the external concentration of HCl increases, the concentration of Cl^- in the resin phase in the form of HCl increases and approaches that of the outside solution. Neglecting activity coefficients, the expression for the diffusion of HCl into the resin phase is:

$$\frac{[Cl^-]\text{resin}}{[Cl^-]\text{solution}} = \sqrt{\frac{1}{1+\frac{[R^-]}{[Cl^-]\text{resin}}}}$$

One gram of a 10% DVB resin, HR, contains about 5 millimoles of H^+ and R^- in roughly 1 c.c. volume; *i.e.*, it is roughly 5 M in H^+ and R^-. When immersed in a 0.1 M solution of HCl, the equation illustrates the fact that the ratio $[R^-]/[Cl^-]$ resin $= \frac{5}{0.1} = 50$, so that the concentration of Cl^- in the resin is very small; namely, about 0.014 M. When the concentration of HCl in solution is 10 M, the concentration of Cl^- in the resin is calculated to be about 8.1 M. This example shows that while the total exchange capacity of the resin was only 5 millimoles, the actual concentration of H^+ in the resin was 8.1 M, 3.1 millimoles greater than the total exchange capacity.

Those ions which enter the resin as a result of Donnan effects can be leached out with water, while those ions needed to neutralize the functional groups remain. In the case of uncharged substances, their concentration in the resin phase may actually exceed the external solution concentration because there exist no charge factors to exclude them and, in addition, the resin phase often acts to hold them selectively. This is the basis for the ion exclusion process described in the section *Historical Development*.

The presence of complexing anions in a solution of metal cations produces a radical change in the exchange properties of the metal ion. The affinity of the metal ion for a cation or anion exchanger may be varied by factors of a million or more. Consequently, most remarkable separations of metal ions are possible. In order to evaluate or predict semiquantitatively the separabilities, it suffices in most instances to know the distribution coefficients of the metal ions and the stability constants of the metal ion for a given number of ligand, or complexing, anions, *e.g.*, MA^+, $MA^0{}_2$, $MA^-{}_3$, etc. where M represents a cation with two positive charges and A an anion with a simple negative charge.

When a cation is complexed, its positive charge is lowered or it may become converted to an anion and therefore its absorption by a cation exchanger will decrease. When the complexed cation is negatively charged it is excluded even more efficiently by Donnan exclusion. However, the absorption of certain ions such as gold, iron, and gallium actually increases with increasing concentration of the supporting electrolyte up to 12 molal in some cases, with distribution coefficients reaching values of the order of 10^8. This behaviour appears to be related to the loss of water in the hydration sheath of the cation in the very concentrated interior of the ion exchanger and to unexplained interaction of the complexed ions with the resin matrix and functional groupings.

In the case of anion exchange resins, the formation of complex ions serves to enhance the absorbability because the Donnan exclusion becomes reduced or nil when the positively charged cation is converted to an anionic complex. When the concentration of supporting electrolyte increases, the absorption of a cationic complex by the anion exchanger increases because the Donnan exclusion becomes less effective. In the case of an anionic complex, the absorption may decrease under the same conditions because of competition from free anions. However, the Donnan effects do not apply when the concentration of the supporting electrolyte becomes very high, *i.e.*, comparable to or higher than that of the fixed ionic groups. In this range, invasion of the resin takes place. It happens that many complexed ions possess an extremely high affinity for an anion exchanger which is generally much higher than that observed by cation exchangers, reaching values of 10^8 or more. An important rule states that the maximum uptake of the metal ion recurs when the number of complexing anions combined with the metal ion results in the formation of a neutral (*i.e.*, uncharged) complex. By means of this rule, and utilizing the known stability constants for complex formation, one can calculate the concentration of the complexing anion at which the absorption of the complexed metal will be at a maximum.

An interesting phenomenon called site sharing is observed when anion exchangers are combined with polyvalent anions. In these cases, the anion exchanger can be considered a base which can absorb acids without exchange of anions. For example, consider a strong base anion exchanger in the sulfate form:

$$R_2SO_4 + H_2SO_4 = R_2(HSO_4)_2$$

Thus, when sulfuric acid is passed through the column of the sulfate form of the anion exchanger, the effluent is free of acid. The absorbed acid can be eluted with water or dilute sodium hydroxide without removing the originally absorbed sulfate ions. As long as the added acid is not too weak (*i.e.*, can donate a proton to the counter ion), it permits the removal and separation of acids from solutions. Inasmuch as the exchanger can be regenerated with water or dilute bases such as calcium hydroxide, commercial processes utilizing these facts have been developed for desalting brackish waters. In such a process the brackish water passes through the hydrogen form of a cation exchanger, releasing acid which is passed through the sulfate form of an anion exchanger; the product is an effluent of acid and salt-free water.

The phenomenon of site sharing permits the separation of many dissociated metal salts from acids, since they do not have H^+ ions to associate with the resin anion. Hence, salts such as Na_2SO_4 and $CuSO_4$ can be freed of acid.

The rate with which an ion exchange reaction reaches equilibrium does not depend on the chemical exchange reaction but rather on the rates of diffusion of the exchanging ions into and away from the ion exchanger. In a well-stirred solution, ion exchange kinetics is governed by one of two diffusion mechanisms: (1) diffusion of the ions through a hypothetical film of solution surrounding each ion exchange particle (F mechanism); or (2) diffusion of the ions through the exchanger particle itself (P mechanism). When both mechanisms are significant in an ion exchange reaction, the condition is said to be "intermediate" (I mechanism). It is helpful to know which diffusion mechanism is operative because it gives both qualitative and quantitative information on how the rate varies with changes in the particle size of the exchanger, concentration of the solutions, charge of the ions and many other parameters, including the internal structure of the resin. Since column methods are usually operated under nonequilibrium conditions, kinetic information helps to predict the performance of a given column process and hence the design.

The differences between ion exchange reactions governed by F or P rate mechanisms may be summarized in general as follows: (1) a P mechanism is independent of stirring or flow rates while the reaction rate of an F-mechanism-controlled reaction increases with increasing stirring or flow rates; (2) in the early stages a plot of the amount of exchange which has taken place against the

square root of time gives a linear plot for a P mechanism; while an F mechanism gives a linear plot when the log of the amount of exchange is plotted against the first power of time; (3) at high concentrations in the surrounding solutions the rates tend to be governed by a P mechanism, and at low concentrations by an F mechanism; and (4) the rate constant varies inversely as the first power of the radius of the exchanger particle for an F mechanism, and as the square of the particle radius for a P mechanism.

Applications.—Since the discovery in 1935 of synthetic ion exchange resins, technical application has increased to the point where it is regarded as a unit operation along with processes such as distillation, adsorption, filtration, and solvent extraction. The major use of ion exchange has been in water softening, in which calcium and magnesium ions, largely responsible for the hardness of water because they form insoluble compounds (*see* WATER: *Hard Water*), are removed by a granular bed of cation exchanger and replaced by sodium ions from the cation exchanger. When the cation exchanger becomes exhausted, by no longer having sufficient amounts of exchangeable sodium left, it is regenerated by passage of an excess of a strong solution of sodium chloride through the bed, thus removing the calcium and magnesium, which are usually discarded.

Water-softening units in individual homes find widespread use in the U.S.; home uses are being developed in Great Britain and in Europe (*see* HOME EQUIPMENT: *Water Softeners*). Some communities soften water before it reaches the home. Numerous industries soften water or provide deionized water in order to improve the quality of various products, such as television tubes, storage batteries, drugs, sugar and paper. A technique increasingly used in water conditioning includes the use of mixed-bed units. The cation and anion exchange resins are mixed so that complete demineralization occurs in the passage of water directly, instead of the usual technique in which water runs through a series of alternate anion-resin-containing tanks. In a mixed bed the resins are regenerated separately by separation of the lighter anion resin by hydraulic classification. After regeneration the resins are mixed, compressed air being used for agitation.

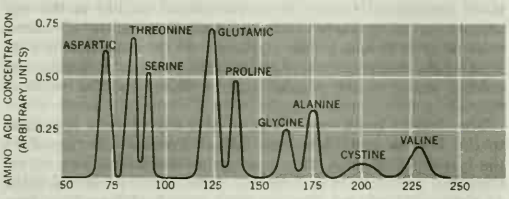

FIG. 2.—ION EXCHANGE SEPARATION OF AMINO ACIDS BY ELUTION WITH BUFFERS OF INCREASING pH FROM A STRONGLY ACID CATION EXCHANGE RESIN. THE SHAPES OF THE CURVES VARY DEPENDING ON FLOW RATE, CONCENTRATION OF SUBSTANCES BEING SEPARATED, TEMPERATURE, LENGTH OF COLUMN AND OTHER FACTORS

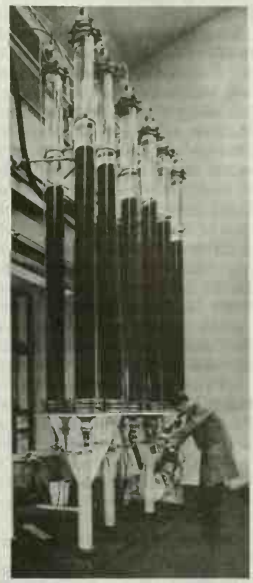
The recovery of metals from industrial wastes and the purification of solutions for re-use are important applications of fixed-bed exchange. However, for such processes to be worthwhile, the recovered metal must have a relatively high economic value, or the savings resulting from the re-use of the solution must be high. The first large-scale use of ion exchange for metal recovery (copper from rayon spinning wastes) took place in Germany beginning about 1940. Deionization of many organic chemicals such as gelatin, sorbitol and glycerol is achieved by ion exchange. Anion exchange resins are used successfully to remove formic acid from formaldehyde.

The isolation of materials present in small amounts is another major use of ion exchange. Streptomycin is a large organic molecule which behaves as a cation. It is concentrated from fermentation broths by absorption on a cation exchange resin, and is recovered in high concentration by displacement with dilute acid.

Rare earths are trivalent cations so similar in properties that ordinary ion exchange separation methods do not work with them. However, it is possible to convert the rare-earth cations into complexes by the use of complexing agents such as citric, lactic and other organic acids. These complexes are usually anions and as such are not absorbed by a cation exchange resin. The rare-earth cations are placed on the top of a bed of a cation exchanger, and elution is facilitated by the use of complexing solutions of suitable pH and concentration. Since the stability of the complex ions varies, the over-all differences in affinity of the individual rare earths for the resin are enhanced. Of further interest is the fact that under given conditions the rare earths are eluted in an orderly sequence based on atomic number. This behaviour led to the first positive identification and subsequent solution of element 61, named promethium. Similarly, the same complex or chromatographic elution technique led directly to the discovery of the elements curium, berkelium, californium, einsteinium and fermium. (*See* CHROMATOGRAPHY: *Ion Exchange Chromatography;* HYDROMETALLURGY: *Ion Exchange.*)



JOHNSON, MATTHEY & CO., LIMITED

FIG. 3.—ION EXCHANGE RESIN COLUMNS EMPLOYED IN THE LARGE-SCALE SEPARATION OF RARE EARTHS

The unusual absorption of complexed ions by anion exchangers has led to numerous commercial and laboratory applications. For example, concentrated hydrochloric acid can be freed from traces of iron impurity by an anion exchanger. The iron is absorbed as the chloride complex and can eventually be removed by elution with water or dilute hydrochloric acid.

Amino acids possess both acidic and basic groups so that they can be absorbed on either cation or anion exchange resins. By suitable variations in pH of an eluting solution, it is possible to obtain separations of individual amino acids, as is shown in fig. 2.

In medicine, weak base anion resins are useful in the treatment of ulcers. When taken orally in the form of a powder or in a capsule, they act to neutralize excess hydrochloric acid in the stomach. Cation exchange resins in the form of mixed potassium-ammonium forms are capable of removing excess sodium from the body, and thus reducing water retention believed to result from the water held by sodium ions.

It is possible only to mention the myriad of other uses of ion exchangers. These include the separations of peptides, nucleic acids, sugars, aldehydes and ketones, and the removal of calcium from blood to prevent coagulation. Since ion exchange resins are essentially acids or bases, they find considerable use as catalysts in hydrolysis and esterification reactions. They have the advantage that as catalysts they can be removed from the reaction mixture by simple filtration and re-used after regeneration.

The technique called ligand exchange has been applied for separations of nonionic molecules such as ammonia, amines, and alcohols. In this process the cation exchanger acts as a carrier in the presence of cations such as Cu^{++}, Ni^{++} or Ag^{+}, which can form complexes with anions or neutral molecules. The complexes are formed in the resin; no ion exchange takes place. Ligand exchange serves as a means of separating molecules which can form complexes with the complexing cation from those which do not.

Similar techniques were employed on the Manhattan Project in 1942 for the separation of plutonium and fission products from uranium by the use of anion exchangers containing complexing

anions such as oxalate, citrate or fluoride. Among many applications is the separation of carbohydrates and related compounds by the use of anion exchangers in the borate or bisulfite form, since the latter anions form complexes with compounds containing hydroxyl groupings.

Many studies of a fundamental nature are carried out with ion exchange resins, since they serve as tools for measuring the stability of complex ions, determination of the state of an element in solution and measurement of activity coefficients. Ion exchangers are widely used in analytical chemistry and other branches of chemistry for the purification of reagents and the preparation of different salt forms of compounds. Salts of acids, when passed through the hydrogen form of a cation exchanger, liberate H^+ which can be titrated, thus yielding the concentration of the original salt. Electrochemical methods of utilizing ion exchange resins, particularly in the form of membranes, are used for demineralization of water and chemicals. In a simple three-compartment cell a cation and an anion exchange membrane divide a container into three regions. Upon application of a current, the cations present in the middle compartment move through the cation membrane, while the anions move into the anion compartment. Thus the middle compartment is demineralized. A series of such cells can be used in which water or other liquids passing continuously through the middle compartment are demineralized. Electrochemical operations become less economical as the salt concentration in solution increases; *i.e.*, current consumption becomes higher. It is impractical to demineralize salt water completely, but it appears practical for reducing the salt concentration of brackish and sea waters to render them fit for drinking or irrigation.

Other methods of desalting brackish water make use of the site-sharing phenomenon (*see* above, *Mechanism of Ion Exchange Reactions*).

IONIA, the ancient name of a region comprising the central sector of the west coast of Asia Minor, bounded by Aeolis on the north and Caria on the south and including the adjacent islands. It extended from Phocaea (*q.v.*) by the mouth of the Hermus (mod. Gediz) river in the north to the territory of Miletus (*q.v.*) south of the Maeander (Buyukmenderes) river (100 mi.). Three flat river valleys, Hermus, Cayster (Kucukmenderes) and Maeander, led down between mountain ranges of 5,000–6,000 ft. to deeply recessed gulfs of the Aegean coast.

Before 1200 B.C. this land bordered on the Hittite empire. In early Greek times the name Asia seems to have belonged to this particular stretch of coast; and it is tempting to assume that it is the same as the Assuwa of the Hittite records. The coastal city of Milawata, named in these records as belonging to Ahhiyawa (perhaps Achaean Greece), is probably Miletus. The name Ionia does not appear in any records of this time, and Homer does not recognize any Ionic settlement of the Asiatic coast in Achaean times. The name Ionia must therefore have been first applied to this coast at a time subsequent to the collapse of the Achaean kingdoms in Greece when Ionic Greek refugees migrated eastward across the Aegean. It must be emphasized that though they formed their own distinctive civilization and dialects, the Greeks of Ionia were only one wing of the Ionic race, which, properly speaking, included the Athenians and many islanders (*see* IONIANS).

On archaeological data the Greek emigration to Ionia may be dated *c.* 1000–900 B.C. In ancient tradition it proceeded mainly from Athens and was led by sons of King Codrus. Modern research shows that the original settlements were numerous and small; but at an early date (8th century or earlier) the leading Ionic cities had consolidated their ownership of the whole coast line and formed an exclusive religious league, the Panionion, with its sanctuary under Mt. Mycale (Samsun Dagi). The cities of Ionia now numbered only 12: Phocaea, Erythrae, Clazomenae, Teos, Lebedos, Colophon, Ephesus, Priene, Myus and Miletus on the mainland, with the islands Chios and Samos. The cities of Ionia were pioneers of civic (and probably constitutional) development in the 8th–7th centuries; these eastern Ionians were individualists by nature and were the founders of Greek poetry and humanism. They seem to have played little part in Greek maritime enterprise of the 8th century in the Mediterranean. But after 700 B.C. Ionic seamen of Miletus and Phocaea were active in northeastern waters (especially the Black sea) and on the Mediterranean coasts of France and Spain, and planted numerous colonies; Miletus alone is said to have been the mother of 90 cities.

The overseas expansion of Ionia was in part due to the need of a new outlet after the deep Ionic penetration inland had provoked opposition and involved a conflict with the rising power of Lydia under the Mermnads. Gyges and succeeding Lydian kings periodically invaded Ionia, and Priene and Smyrna fell. But it was not till the reign of Croesus (*c.* 560–546) that the bulk of the Ionians came under Lydian sway. In this period, and down to 500 B.C., Ionic rational thought dominated the intellectual life of Greece. While the study of geography and nature was based on intelligent observation, research into matter and the universe proceeded on a more theoretical basis, especially in the academic atmosphere of Miletus (*see* THALES; ANAXIMANDER), and Ionians at home and overseas laid the foundations of Greek philosophy (*e.g.*, Heraclitus, Pythagoras, Parmenides). Ionic had necessarily become the language of literature and learning. The colossal temples of Ephesus and Samos were not only masterpieces of Ionic architecture but also bold engineering feats. Ionic sculpture combined geometrical form with an exceptional facility in the representation of textures, and the applied scientists of Samos were pioneers of cast bronze statuary. At the same time not the least of the achievements of the Ionians was the propagation of culture among native peoples in Asia Minor and the south of France.

The cities of Ionia were unable to offer any effective opposition to the Persian army after the fall of Croesus. Instigated by the tyrants of Miletus, they rose against Persia *c.* 499 B.C., but their fleet was crushed at Lade five years later. After the battle of Salamis (480 B.C.) they revolted again and helped to form the Delian league, which degenerated into an Athenian empire. Holding a precarious balance between Persian grandees and Athenian democracy, the cities of Ionia suffered from faction and disillusionment, which were not dispelled by the advent of Spartan forces after the Athenian disaster in Sicily in 413. In the 5th century they acquired a reputation for easy living, and their prosperity seems to have declined under Athenian rule. Traded to the Persian king by the Spartans in 387 B.C., the cities of Asia reverted to the uneventful routine of Persian rule punctuated by occasional local despotisms and the maneuvers of warring satraps.

In 334 B.C. the cities (save Miletus) transferred their loyalty to Alexander III the Great and were rewarded with freedom and democracy. With their experience of imperial affairs individual Ionians were particularly well qualified to assume important positions in the newly conquered lands of the east. After Alexander's death (323 B.C.) the Ionic cities were nominally independent under the sovereignty of Antigonus I (until 301), then subject to Lysimachus (till 281). Until the opening years of the 2nd century they were poised between the Seleucid (Syrian) alliance by land and Ptolemaic (Egyptian) supremacy along the coast; but even before this time some of the cities had embraced the alliance of the ambitious new dynasts of Pergamum. By the will of Attalus III of Pergamum (d. 133 B.C.) Ionia passed into the hands of the Romans. Thanks to Alexander's victories and the shifting east-

ward from the Greek mainland of the focuses of power and culture, the Ionic cities had enjoyed two centuries of renewed prosperity. But in the new Roman province of Asia honest administration was sacrificed to considerations of profit and political advantage in Rome, and the cities suffered without redress from the extortions of Roman tax-farming corporations and governors; and after the great rising when Mithradates VI overran Asia Minor they were crippled by the immediate levying of five years' tribute in 84 B.C. Thereafter they suffered from depredations of pirates and the exactions of the leaders in the Roman civil wars.

The establishment of universal peace by Augustus after the battle of Actium (31 B.C.) terminated 100 years of distress in Ionia. Under the empire the principal cities experienced a revival of prosperity and civic amenities, and many of the spectacular ruins on their sites date from that time. Ephesus, Miletus, Smyrna and Chios were among the most splendid cities of the Roman world and continued to flourish in Byzantine times.

IONIAN ISLANDS (IONIOI NISOI), the collective name for the Greek islands of Corfu (Kerkyra), Cephalonia (Kephallenia), Zante (Zakynthos), Leukas, Ithaca (Ithaki), Cythera (Kythera) and Paxos (Paxoi), with their minor dependencies. These islands, though often described as the Heptanesos ("Seven Islands"), have no geographic unity. The name is derived from *Ionios,* the ancient name for the sea in which the islands (except Cythera) stand, itself of uncertain origin. The political unity of the islands is comparatively modern. Pop. (1961) 212,573. Total area 873 sq.mi. (2,260 sq.km.).

The Ionian Islands consist almost entirely of Cretaceous and Tertiary beds, but in Corfu Jurassic deposits have been found. The oldest beds which have yet been recognized are shales and hornstones with Liassic fossils. These are overlaid conformably by a thick series of platy Viglàs limestone, representing the rest of the Jurassic and the lower Cretaceous. Then follow dolomites and unbedded *Hippurites* limestones, evidently of Upper Cretaceous age. The Eocene beds are folded with the Cretaceous. Both occasionally assume the form of Flysch. Miocene beds are found in Corfu and Zante, and Pliocene deposits cover much of the low ground.

For physical description and classical history, *see* the articles on the individual islands.

Medieval and Venetian Periods.—The beginning of Heptanesian history dates from the 9th century. Leo the Philosopher (*c.* A.D. 890) formed all or most of the islands into a distinct province of the eastern empire under the title of the Thema of Cephallenia. Robert Guiscard captured Corfu (1081) and Cephalonia, but his early death prevented the establishment of a Norman dynasty. When the Latin empire was established at Constantinople in 1204 the Venetians received Corfu. After defeating the Genoese corsair Leon Vetrano, the senate granted fiefs in Corfu to ten noble families in order that they might colonize it (1206). The Greek "despot" of Epirus, however, captured the first Venetian colony in 1214, and a long period of Epirote, Sicilian and Neapolitan-Angevin rule followed, till in 1386 the people of Corfu made voluntary submission to the Venetian republic. Paxos, created a barony, was treated as part of Corfu.

The county palatine of Cephalonia (with Zante), seized by Matteo Orsini in 1194, owned the suzerainty first of Venice, then of Achaia, to which it was annexed in 1324. In 1357 it was bestowed upon the Tocco family of Benevento, and was united with Leukas (Italian Santa Maura) and Ithaca (called Val di Compare) in the duchy of Leucadia. In 1479 the Turks annexed these four islands. Over a period of time, however, they became Venetian; Cephalonia and Ithaca in 1483–85 and from 1500 onward; Zante in 1482 and from 1485 and Leukas in 1502–03 and from 1684. Cythera (Italian Cerigo), a Venetian marquisate of the Venier family from 1207, became a Venetian colony in 1363, but was parceled out between Venice and the Venier in 1393.

The Venetians, who exacted heavy contributions from the islands, won the adherence of the principal local families by the bestowal of titles and appointments; the Roman Catholic Church was established and the Italians and Greeks intermarried. Greek ceased to be spoken except by the peasantry who remained faithful to the Orthodox communion. On the fall of the Venetian republic in 1797 the treaty of Campo Formio annexed the Ionian Islands to France, but a Russo-Turkish force drove out the French at the close of 1798 and in the spring of 1799 Corfu capitulated. By treaty with the Porte in 1800 the emperor Paul erected the "Septinsular republic," but the treaty of Tilsit (1807) declared the islands an integral part of the French empire and they were incorporated with the province of Illyria (*q.v.*). British forces under Gen. John Oswald took Zante, Cephalonia and Cythera in 1809, and Leukas in 1810; Colonel (afterward Sir Richard) Church (*q.v.*) reduced Paxos in 1814; and after the abdication of Napoleon, Corfu was, by order of Louis XVIII, surrendered to Sir James Campbell. By the treaty of Paris (Nov. 9, 1815) the contracting powers (Great Britain, Russia, Austria and Prussia) agreed to place the "United States of the Ionian Islands" under the exclusive protection of Great Britain.

British Protectorate.—The constitutions, voted by a constituent assembly in 1817 and applied in the following year, placed the administration in the hands of a senate of six members and a legislative assembly of 40 members; but the real authority was vested in the high commissioner, Sir Thomas Maitland ("King Tom"). The successive British commissioners, Gen. Sir Frederick Adam (1823), Lord Nugent (1832) and Sir Howard Douglas (1835–41), did much for the administration, justice, education and communications of the islands, but their firm, often despotic rule was resented by the inhabitants, the principal opponent being the historian Andreas Mustoxidi (d. 1861). A complete change of policy was inaugurated in 1841–43, and Lord Seaton (1843–49) was induced by the European disturbances of 1848 to initiate a number of important reforms. But the party in favour of union with Greece was rapidly growing. Serious insurrections of the peasantry, especially in Cephalonia, had to be put down by military force, and the parliament passed a resolution in favour of immediate union with Greece.

Cession to Greece.—Contrary to the expectations of the Greeks, W. E. Gladstone, who toured the islands as high commissioner extraordinary, did not propose the abolition of the protectorate, and his successor, Sir Henry Storks, seemed indifferent or blind to the popular feeling. However, on the abdication of King Otho of Greece in 1862 the British government declared to the provisional government of Greece that the selection of Prince William George of Glücksburg would be followed by the cession of the Ionian Islands. After the prince's election by the national assembly in 1863 the high commissioner laid before the Ionian parliament the conditions of the cession. The rejection of one condition, the demolition of the fortifications of Corfu, led to a new prorogation, but on March 29, 1864, the plenipotentiaries of the five great powers signed the treaty by which the protectorate was ended. Neutrality was confined to Corfu and Paxos. On May 3, 1864, Sir Henry Storks left Corfu with the British troops and men-of-war. King George made his entry into Corfu on June 6.

After their annexation to Greece the history of the Ionian Islands was uneventful. Their prosperity somewhat declined. Corfu with Paxos; Cephalonia with Ithaca; Leukas and Zante form four separate *nomoi* or departments; Cythera is attached to the *nomos* of Attica. The islands retained the exemption from direct taxation which they enjoyed under the British protectorate; in lieu of this an ad valorem tax was imposed of 20½% on exported oil and a tax of 6% on wine exported to Greek ports; these commodities were further liable to an export duty of 1½% levied on all agricultural produce and articles of local manufacture. Many of the islands are subject to earthquakes, and the towns of Ithaca, Cephalonia and Zante were virtually destroyed in the disaster of 1953. A large-scale program of reconstruction was undertaken.

IONIANS, an important eastern division of the classical Greek people, distinguished by a well-marked dialect (*see* below), who gave their name to the district called Ionia (*q.v.*).

The Ionians as a people are mentioned only once in the Homeric epics, as an apparently unimportant contingent fighting alongside the Athenians; the (later Ionian) city of Miletus was still occupied by non-Greek Carians. In the Homeric *Hymn to Apollo*, however, composed by the "blind man of Chios" whom the Greeks supposed to be Homer himself, the Ionians are already the great and wealthy people who frequent the festival of Apollo at Delos. The date of the *Hymn* is probably not far from that of the first certain mention of Ionians in an oriental document, when Sennacherib, in 696, claims to have rounded up Ionian pirates or settlers near Tarsus and "given peace to Cilicia and Tyre." It was the generation of the first great outpouring of Greek colonization since the occupation of Ionia itself, a movement which brought Ionians of Euboea to eastern Sicily and to Cumae near Naples, and Samians to Nagidus and Celenderis in Pamphylia. Eastern expansion was checked only by the resistance of the eastern peoples. "Ionians" (Persian *Yauna*, Semitic *Yawani*; *cf.* Homeric *Iawones*) became and remained the oriental term for all Greeks. "Javan" figures in Hebrew lists of the descendants of Noah as a son of Japheth and "father" of the western sea peoples (Gen. x. 2–5; I Chron. i, 5–7; compare Iapetus [*q.v.*], husband of the nymph Asia, in Greek mythology). *Yunani*, moreover, remains the term for Greek in Turkish and Arabic.

Ionia was said to have been colonized from Attica, though also from other regions of central Greece, by people displaced by Dorian and Boeotian invaders from the northwest; this is confirmed by the fact that the four subdivisions of the people called *phulai* ("tribes"), found in Attica, reappear in Miletus and other Ionian cities. Another similar (but triple) tribal system, as well as their dialect, distinguished the Dorians (*q.v.*). Solon of Athens (*c.* 600) already calls his country "the senior land of Ionia." The eponymous hero Ion, however, did not figure among the traditional names of ancient kings of Athens, and he had therefore to be fitted into the mythical history as a war leader and ally; as a grandson he was also fitted into the heraldic genealogy of the "children of Hellen," said to have appeared already in a lost poem of Hesiod. By the time of Herodotus (*c.* 450) Greek thinkers had worked out a detailed ethnological theory which identified the Ionians with the aboriginal element in Greece (also called *Pelasgoi*, originally the name of a real, perhaps north Aegean people; *see* Pelasgians) and the Dorians with the immigrant northern Hellenes proper, "a very migrant people." Both in their way might therefore claim to be the "true" Greeks, and an element of racialism was introduced into Greek interstate polemics. Peloponnesian Dorians affected to despise as "soft" the Ionians of Asia, who (thanks to their exposed position) had been subjected by Persia, and Thucydides (viii, 25) finds it worthy of a passing comment when, in a battle between two allied forces, an Ionian wing on each side defeats a Dorian wing. This feeling, much exploited by city-state patriots, is even reflected in some modern writings on Greece, influenced especially by K. O. Müller's *Die Dorier* (1824). In actual fact, the culture and way of life of maritime Dorian cities, such as those of Rhodes or the colonies in Sicily, resemble those of Ionia rather than of inland and militarist Sparta; and when the Athenians made war on democratic (Dorian) Syracuse, Thucydides comments that they found their toughest antagonists in a people so like themselves.

In the dialect the *w*-sound represented in Greek by the digamma (*see* F) was lost early, and initial aspirates tended to be dropped. The broad *ā* (as in "father") was modified into *ē*, not far from English *-ay* in "say" (so, *mētēr*, "mother," for Doric *mātēr*; *cf.* Latin *mater*). Some short vowels were lengthened before a nasal or liquid that preceded a lost digamma; *e.g.*, *xeinos*, *kourē*, for Attic *xenos*, *korē*. In the Ionic of the Homeric poems in their present form a few non-Ionic forms survive, mostly, but not all, where the Ionic equivalents were unmetrical; even where the manuscripts have Ionic, it is sometimes necessary for metrical reasons to substitute a non-Ionic form. These non-Ionic forms are called "Aeolic," a term properly applicable to the dialect of the Greeks north of Ionia proper on the Asian coast and in the adjacent island of Lesbos and parts of the northern Greek peninsula, but loosely used by ancient scholars to describe a wide range of dialects, from the archaic (Mycenaean?) Arcado-Cypriot to some northwestern dialects akin to Doric. It seems clear, however, that the poems, or at least some traditional material used by Homer, existed in a somewhat different, perhaps less specialized dialect, before being reduced to literary Ionic. The development of literary Ionic may therefore have been completed only in the latest prehistoric times (*c.* 9th–8th centuries B.C.?) among the Greeks who had colonized the central part of the eastern Aegean coast since the end of the Bronze Age, and the islanders of the central Aegean, who met for worship and festivities at the holy islet of Delos. In Attica, alone on the Greek mainland, a kindred dialect was spoken, but one in which the characteristic features of Ionic were less pronounced.

The contribution of Ionians to the Greek achievement was of major importance, including the Homeric epic, elegiac and iambic poetry, the work of the first philosophers and the first histories and geographical works (the first European prose), as well as a major part in the opening up of the Black sea, especially by Miletus, and the western Mediterranean by Phocaea with its colony of Massilia (Marseilles). In the age after Alexander the Great the Athenian (Attic) form of Ionic, as the literary language par excellence, eclipsed other dialects and became the basis of the koine or "common speech," the language of practically all later Greek writing (including the New Testament) to the present day.

IONIAN SCHOOL OF PHILOSOPHY, an expression sometimes used to designate collectively a number of Greek scientific philosophers of the 6th–5th centuries B.C., including Thales, Anaximander, Anaximenes, Heraclitus, Anaxagoras, Diogenes Apolloniates, Archelaus and Hippo (*qq.v.*). While Ionia was the original centre of their activity, they differed from one another so much in their conclusions that it is scarcely exact to call them a school, though their common concern to explain phenomena in terms of matter or of physical forces distinguishes them from later thinkers.

IONIC METRE, a variety of classical metre found especially in Greek lyric and drama. The rhythm was considered to have oriental associations. The metron is ⏑⏑––. It is repeated to form dimeters, trimeters and even longer verses. Ionic verses may be varied by the omission of the second long of the first metron (syncopation): ⏑⏑–|⏑⏑––, or of the last (catalexis): ⏑⏑––|⏑⏑–. Occasionally, the second long of the metron is resolved into two shorts or even replaced by a single short. Horace uses pure ionics in one ode, iii, 12:

⏑⏑– ––| ⏑ ⏑––| ⏑⏑ – –| ⏑ ⏑ ––|

miserar(um) est nequ(e) amori dare ludum neque dulci.

The anacreontic, or "anaclomenon," is a variation of the ionic dimeter said to be produced by anaclasis; *i.e.*, the reversal of the fourth and fifth elements to produce ⏑⏑–⏑–⏑– –. This verse is found in Anacreon, Attic drama and the *Anacreontea*. The galliambic, the metre of Catullus lxiii, is basically a compound of anacreontic and catalectic ionic dimeter, with the second long of the first metron resolved:

⏑ ⏑ –⏑ –⏑ – –‖⏑⏑– ⏑⏑| ⏑⏑–

super alta vectus Attis celeri rate maria.

Ancient metricians posited the existence of an ionic metron *e maiore*— — ∪∪, but passages said to be in this metre can always be scanned in other ways. *See* further PROSODY, CLASSICAL.

(L. P. E. P.)

IONIC ORDER: *see* ORDER.

IONIC THEORY: *see* ELECTRICITY, CONDUCTION OF: *Conduction in Gases;* ELECTRICITY: *Ions.*

IONOSPHERE, an electrically conducting sphere completely surrounding the earth. The name is derived from the presence of ions and free electrons produced by the sun's ultraviolet radiation. The ionosphere exists in the earth's outer atmosphere, above the stratosphere and mesosphere and extends from heights of approximately 80 to 300 km. (50 to 200 mi.). (*See* ATMOSPHERE.) It was more commonly known as the "Kennelly-Heaviside layer" in the period 1901–30. The ionosphere makes possible all long-distance radio communications using high-frequency waves, since it reflects the signals back to earth, keeping them from being lost in space.

Before 1901 it was thought that wireless (radio) waves were useful only for short-distance communications, since they were known to travel in straight lines, like light. However, the success of Marconi's transatlantic tests in 1901 led to theories developed independently by A. E. Kennelly and O. Heaviside that radio signals were reflected back to earth from an electrically conducting region in the earth's outer atmosphere. A similar region had also been proposed by Balfour Stewart about 1882, to explain systematic changes observed in the earth's magnetic field. (*See* GEOMAGNETISM.)

Direct measurements of the ionosphere were not made until 1925, when, in England, E. V. Appleton and M. A. F. Barnett reported an experiment based on a wave-interference technique, and, in the United States, G. Breit and M. A. Tuve recorded radio echoes using a new system of transmitting short pulses of radio waves and receiving their echoes. In the latter experiment it was noted that pulses transmitted vertically with frequencies below 1 or 2 mc. per second were either reflected or absorbed by the ionized layers, whereas frequencies above 15 or 20 mc. usually passed completely through the atmosphere and were lost to space. This is because the higher frequency radio waves required a greater electron density for reflection. The time required for a pulse to travel to the ionosphere and back was a measure of the height of the reflecting layer.

This pulse technique has been developed to the point where equipment to record automatically the effective height of reflection for each frequency from 0.5 to 20 mc. is in wide use throughout the world. As a result, knowledge of how the distribution of free electrons changes with place, time of day, solar activity, etc., is quite complete.

The ionosphere contains two principal regions of free electrons. The lower (E-region) normally occurs at heights of 90 to 120 km. (55 to 75 mi.), while the upper (F-region) is usually found from 150 to 300 km. (100 to 200 mi.) above the earth. Rocket observations and theoretical calculations have indicated that the so-called layers of free electrons are, in fact, broad maxima of electron density, and that the ionosphere is highly ionized throughout.

The daylight value for the E-region maximum is roughly 10^5 free electrons per cm.^{3}, while in the daytime the F-region often has two maxima, known as the F_1- and F_2-layers. The F_2-layer, which is above the F_1-layer and is more persistent, may have about 10^6 electrons per cm.^{3}, though this is highly variable.

Characteristics of ionospheric layers change with time of day, season of year and geographical location. Variations in the normal E- and F_1-layers are generally small, but abnormal or sporadic ionization in the E-region is rather common in summer. Fluctuations in the F_2-layer are often relatively large and irregular, and such fluctuations are particularly pronounced during magnetic storms. The 11-year sunspot cycle and other forms of solar activity also influence ionospheric characteristics.

The ionosphere controls long-distance radio communication by establishing upper and lower limits of usable wave frequencies. The upper limit is determined by its reflecting properties and the lower limit by absorption in the lowest part of the ionosphere, called the D-region. During periods of solar activity the enhanced ultraviolet and X-radiation from the sun increases the ionization in the D-region, causing an increase in the absorption of radio waves, and this results in poor radio communication on those channels that depend on ionospheric reflections.

IOWA, popularly known as the "Hawkeye state," a north central state of the United States, is bounded north by Minnesota, east by the Mississippi river, which separates it from Wisconsin and Illinois, south by Missouri and west by the Missouri and Big Sioux rivers, which separate it from Nebraska and South Dakota. The state's total area is 56,032 sq.mi., of which 258 sq.mi. are water surface.

Various meanings have been ascribed to the word "Iowa": among the most common are "beautiful land" and "this is the place." It is commonly supposed that the name "Hawkeye" was that of an early Indian chief. The state is the 25th in size of the states of the union. The state capital is Des Moines, and the state entered the union, Dec. 28, 1846, as the 29th state. The oak tree was designated the state's official tree in 1961. The wild rose is the state flower, and the eastern goldfinch is the state bird. The state flag consists of three vertical stripes of blue, white and red. In the centre of the white stripe is depicted a spreading eagle which bears in its beak blue streamers. Inscribed upon the streamers is the state motto: "Our liberties we prize and our rights we will maintain" and the word "Iowa" is in red letters below the streamers.

PHYSICAL GEOGRAPHY

Physical Features.—Iowa lies wholly in the prairie plains region between the extremes of approximately 40° 22′ and 43° 30′ N. and 90° 08′ and 96° 38′ W. Since its surface was overrun by one or more of the great ice sheets of the glacial epoch, the largest portion of the state is prairie tableland. The lowest elevation, 480 ft. above sea level, is at Keokuk in the southeastern part of the state. From this point the land rises in gentle swells to the point of highest elevation (1,675 ft.) in Osceola county in the northwestern part of the state. The greatest departures from the prairie surface are in the northeast and southwest. In the northeast—the so-called driftless area of Iowa—cliffs rise almost vertically from the banks of rivers to heights of from 300 to 400 ft. From the summit of such cliffs to the crest of a divide, usually a few miles distant, is another ascent of 300 ft. or more, which terminates occasionally in knob-topped hills crowned with small cedar trees. In the west, southward from the mouth of the Big Sioux river, a line of moundlike bluffs rises abruptly to a height of from 100 to 300 ft. from the flood plain of the Missouri river. Because of glaciation, the northern half of the state is more broken and irregular and has more shallow lakes and ponds than the southern half.

A broad watershed, extending in a southerly direction from Spirit lake on the northern border, divides the state into two drainage systems. That to the east, comprising about two-thirds of the whole area, is drained by tributaries of the Mississippi, of which the Des Moines, the Skunk, the Iowa (and its tributary the Cedar) and the Wapsipinicon are the largest. These streams have long courses and moderate slopes. The region to the west of the watershed is drained by tributaries of the Missouri, such as the Big Sioux, the Little Sioux, the Boyer and the Nishnabotna.

Climate.—Iowa has a climate of great extremes. The mean annual temperature is 49° F. (about 10° C.); the average range of extremes per year is about 135° F. The average mean annual temperature at Sibley in the northwest is 44°, while at Keokuk in the southeast it is 52.4°. Des Moines, located nearer the centre of the state, has an average mean annual temperature of 50.9°.

Rainfall is very unequal in its distribution throughout the year, as between the same periods of different years and as be-

tween the different parts of the state. While the mean annual precipitation is 31.44 in., about 71% of this falls during the six months from April 1 to Oct. 1. May, June and September are generally the wettest months. Within any one year the precipitation is usually less in the western part of the state than it is in the eastern part; the western part also has a greater percentage of its rain in the spring and summer than has the eastern part. Though the average frost-free growing season is from May 2 to Oct. 7, killing frosts may occur later or earlier. Injury to crops from drought and hot winds occurs infrequently, but harmful effects from excessive rainfall, hailstorms and prolonged excessive heat are more common.

Soil.—The fertile soil of Iowa, because of its depth and porous nature, is capable of withstanding the extremes of wetness and dryness remarkably well. Perhaps no other state in the union has such superior soil for agriculture; no other state has so many acres of grade A land or so large a proportion—from 85%–90%—of its land suitable for cultivation.

The soil is of four kinds: till (or drift), alluvial, loess (or bluff) and geest (or gravelly earth). Dark drift, composed chiefly of clay, sand, gravel, boulders and lime, is both the soil and subsoil of the greater part (about 66%) of the state and is especially predominant in the north and northwest. Alluvial soil, composed of material washed from other soils and decayed vegetable matter, covers about 6% of the surface of the state. This type of soil is found in the river bottoms, particularly in the valley of the Missouri, and varies much in fertility. Loess soil, chiefly a mixture of porous clay and carbonate of lime, forms the bluffs bordering the bottom lands of the Missouri and is common in the northeast. In fertility loess is not inferior to the better drift. Geest is found particularly in the northeast, but it covers less than 1% of the area of the state.

Vegetation and Animal Life.—When the first settlers came to Iowa they found the rolling prairies covered with deep, coarse grasses, berries and wild flowers. Forests of birch, maple, hickory, oak, elm, walnut, ash and cottonwood trees grew in the river valleys and in scattered areas. The Cedar river derives its name from the red cedar, the only evergreen native to the area. Native grasses and the original timber, except in a few places, have been destroyed; yet, trees and plants, some native and some immigrant, grow in profuse variety. The prairie rose, aster, honeysuckle, primrose, shooting star, violet, blue phlox, trillium, bloodroot and many types of ferns are common.

Situated along the Mississippi and Missouri flyways, Iowa is a haven for birds of many types. The robin, eastern goldfinch, starling, junco, blue jay, chickadee, red-winged blackbird, woodpecker, crow and meadow lark are frequently seen. The wild turkey, once plentiful, is almost extinct; the ring-necked pheasant, imported into the state, is now a major game bird. Owls and hawks are the principal birds of prey.

Wolves were once numerous in the region, but they have since disappeared. Except for the white-tailed deer, large game animals are rare. Among the small wild animals found are the beaver, muskrat, raccoon, skunk, jack rabbit, cottontail rabbit, ground hog, gopher and chipmunk. Although more than 100 kinds of fish have been seen in the area, the most common are the catfish, bullhead, carp, buffalo, sucker, walleyed pike, smallmouthed bass, rainbow, brook and brown trout, crappie and bluegill. There are about 25 varieties of reptiles, of which three (all rattlesnakes) are poisonous.

State Parks and Historical Sites.—The state conservation commission has jurisdiction over state parks, reserves and monuments; state forests and forestry; and state waters. Providing for the protection, propagation and preservation of fish, game and fur-bearing animals is an important function of the conservation commission. It maintains more than 120 wildlife refuges comprising about 35,000 ac. and more than 160 public hunting grounds totaling approximately 91,000 ac. Nearly 100 lakes, artificial and natural, are also the responsibility of the commission.

State parks include Backbone (near Strawberry Point); Dolliver Memorial (near Fort Dodge); Geode (near Burlington); Lacey-Keosauqua (near Keosauqua); Lake Ahquabi (near Indianola); Lake Darling (near Fairfield); Lake Macbride and Palisades-Kepler (both near Cedar Rapids); Lake Wapello (near Ottumwa); Ledges (near Boone); Nine Eagles (near Leon); Pike's Peak (near McGregor); Pilot Knob (near Forest City); Rock Creek Lake (near Kellogg); Springbrook (near Guthrie Center); Stone (near Sioux City); Waubonsie (near Sidney); and Wild Cat Den (near Muscatine).

Various historical sites attract thousands of visitors annually. Among these are the Amana colonies, which were established in 1855 as experimental religious communities; the Old Capitol, which is now the administrative office of the University of Iowa; Plum Grove farm, at Iowa City, the home of Robert Lucas, Iowa's first territorial governor; Effigy Mounds National monument, at Marquette (established 1949), which contains burial mounds of prehistoric Indians; Fort Atkinson State park; former Pres. Herbert Hoover's birthplace and the Herbert Hoover Library-Museum (dedicated 1961) at West Branch; the grave of Julien Dubuque at Dubuque; and the Anton Dvorak monument at Spillville.

HISTORY

Early Inhabitants.—The name "Iowa" was taken from the tribal name of a group of Siouan Indians who occupied the area when it was first seen by white men—the Frenchmen, Father Jacques Marquette and Louis Jolliet, in 1673, and Father Louis Hennepin, in 1680. In the century following the visits of these early travelers, explorers and missionaries did little to disturb the Indians of the region. During those years, however, the Ioway tribe was pushed westward and largely supplanted by the tribes of Sauk and Fox, who had previously been driven from Michigan by the French.

First White Settlements.—No permanent white settlement had been established in Iowa when the French, who had held it since 1682, relinquished control to the Spanish in 1762. During the period of Spanish control, there was some penetration and exploitation of the area. The lead mines near the Mississippi river were a major attraction, and to these mines came a French Canadian, Julien Dubuque, who in 1788 obtained an Indian grant giving him the right to carry on mining operations near the present site of the city which today bears his name. Although Dubuque received confirmation of his grant from the Spanish governor, the wealth he sought eluded him and he died bankrupt in 1810. Louis H. Tesson in 1799 and Basil Giard in 1800 also received Spanish grants in Iowa, but were similarly disappointed.

Iowa was retroceded to France in 1800 and, as part of the Louisiana Purchase in 1803, became United States territory. During 1804–05 it was a part of Indiana territory; it was made a part of Louisiana territory from 1805 to 1812. Indian hostility forced the abandonment of the first American post in Iowa, Ft. Madison, near the mouth of the Des Moines river, during the War of 1812. After the conclusion of peace in 1815 the Sauk chief, Black Hawk, nourished a bitter hatred toward settlers, and in a final attempt to recover lands in Illinois, he instigated a war against the United States in 1832. Black Hawk's defeat resulted in the cession of nearly 9,000 sq.mi., the first of many Indian land cessions between 1832 and 1851. From 1812 to 1821 Iowa was a part of Missouri territory; from 1821 to 1834 it was a part of the unorganized territory of the U.S. After Black Hawk's war, settlers began to pour into Iowa. In 1834 it was a part of Michigan territory; in 1836 it was a part of Wisconsin territory. Government land surveys were not begun until 1836, making the first settlers technical trespassers on the public domain. Ostensibly to protect their holdings, the settlers formed voluntary associations or "claim clubs." Although proceedings of the associations relating to land claims were later recognized by U.S. authorities, they were often dominated by speculators rather than farmers.

Statehood and Early Problems.—Iowa was separated from Wisconsin in 1838 and the question of applying for admission into the union as a state was voted on as early as 1840. The measure was defeated then and again in 1842 by those who wished to avoid an increase in taxes. Finally, in 1844, a convention was held at Iowa City, a constitution framed and application for admission to the union made. Congress, however, rejected the application

Bottom right: Iowans watching a horse-pulling contest at the state fair

because it disagreed with the proposed boundaries of the new state. A second constitutional convention was called at Iowa City in 1846; it drew up the present boundaries of the state and prohibited the organization of banks of issue. Congress approved the second constitution and Iowa was admitted to the union in 1846.

Burlington had served as temporary capital of the territory until 1839. In that year, Iowa City was designated as the capital city but was replaced by the present capital, Des Moines, in 1857.

Statehood by no means solved all problems faced by Iowa pioneers. The Spirit lake massacre of 1857, in which about 40 settlers were killed, provided grisly proof that Indians were still a danger to isolated settlements. Elsewhere, lawless elements defied regularly established authorities, and as a result vigilance committees were formed. From 1846 to 1860 there were approximately 45 lynchings in which 70 victims were summarily put to death. Sectional feeling, running rampant over the nation, also created problems in Iowa, resulting in a shifting of political allegiances. Although the Democratic party had been in power since statehood, the state supported the Republican party after the latter's formation in 1854. The American Civil War claimed the lives of more than 12,000 Iowans.

Issues and Reforms.—Economic expansion characterized the years following the American Civil War. From 1860 to 1910, for example, more than 9,000 mi. of railroads were constructed in Iowa. Yet there was considerable agrarian discontent during this period, as some of the farmers felt that they did not share adequately in the general prosperity. Thus, farmers' organizations and third parties, such as the Patrons of Husbandry (the Grange), the Greenback party and the Populist party, developed significant followings. Though not markedly successful in electing candidates, such movements forced the major parties to adopt reform programs and to enact progressive legislation.

Particularly important issues in Iowa were tariff reform, railroad-rate regulation and the prohibition of the manufacture and sale of intoxicating liquors; but the reformers in these areas had indifferent success. The tariff question split the Republican party when its more progressive members supported the "Iowa Idea"; *i.e.*, the expansion of trade through tariff reciprocity and downward revision of rates. Advocates of railroad-rate regulation were never able to accomplish all their aims, although a railroad commission was established as a result of their efforts. Prohibition was steadily debated from 1882, when it was attempted unsuccessfully, until the repeal of the prohibition (18th) amendment to the U.S. constitution in 1933. In that year the general assembly passed laws legalizing the sale of beer with 3.2% alcoholic content and established a state monopoly for the sale of intoxicating liquors, with a state liquor control commission in charge.

Reformers in Iowa achieved their most important victories in the field of welfare legislation. In 1913 the general assembly passed an employers' liability and workmen's compensation act and a mothers' pension act. The Perkins law of 1915 provided free treatment for crippled children of indigent parents. In 1917 a child welfare station for the study of children's problems was established at Iowa City.

The depression of the 1930s had the same effects in Iowa that it had in other areas, and the demand for relief legislation was met on both a state and national level. Concern for the aged found expression in a system of old-age pensions begun in 1935. In 1936 the Iowa employment security commission was created to encourage industry to provide more stable employment, maintain a free public employment service and grant benefit payments to those unemployed. A large-scale construction project to provide a system of dams for the upper Mississippi river was begun in 1931 and continued throughout the following decade. The agricultural program of the New Deal was a response to distress in the farm belt of which Iowa is such a significant part. The Iowa state planning board was created in 1937 to deal with various problem areas, and it continued in service until 1939.

The first women's army corps training camp was established at Ft. Des Moines, during World War II, and navy fliers were given training at Ottumwa and Iowa City.

In state and national politics Iowa has been predominantly Republican since before the Civil War. In presidential elections since 1900 only Woodrow Wilson (1912), Franklin D. Roosevelt (1932 and 1936) and Harry S. Truman (1948) carried the state for the Democrats. Iowa has elected only five Democratic governors since the Civil War: Horace Boies in 1889 and 1891, Clyde L. Herring in 1932 and 1934, Nelson G. Kraschel in 1936, Herschel C. Loveless in 1956 and 1958 and Harold E. Hughes in 1962.

GOVERNMENT

Iowa's present constitution was adopted in 1857, the constitution of 1846 having been superseded chiefly because it prohibited banking corporations. The constitution may be amended by an affirmative vote of both houses of two successive legislatures, followed by a majority vote of the electors of the state voting on the proposed amendment. Suffrage is granted to all citizens of the United States (except idiots, insane persons and those convicted of an infamous crime) who are at least 21 years of age, have resided in the state for six months and in one county for 60 days preceding an election. The franchise was conferred on Negroes by an amendment adopted in 1868. Women did not vote until passage of the federal amendment in 1920.

The supreme executive authority in Iowa is the governor. Other elective executive officials are: the lieutenant governor, secretary of state, treasurer, auditor, attorney general and secretary of agriculture. All officers must be citizens of the United States and have the age and residence qualifications of voters. The governor and lieutenant governor must, in addition, be at least 30 years of age and must have resided in Iowa for at least two years preceding election. All are elected for two-year periods.

The governor has extensive appointive power, oversees the making of the budget and may veto acts of the general assembly, although such acts may be passed over his veto by a two-thirds majority of both houses. The lieutenant governor is ex-officio president of the senate and takes the office of governor in case of the death, resignation or removal from office of the chief executive. The governor, secretary of state, auditor, treasurer and secretary of agriculture make up the executive council. This ex-officio board canvasses state election returns, supervises the incorporation of building and loan associations, appoints the board of mine inspectors, allocates space in the capitol and other buildings used by the state government to the various offices and departments and has other supervisory duties.

In addition to the elective offices a number of subordinate administrative offices have been created by the legislature. These offices, filled by appointment, include those of the adjutant general, the commissioner of public health, the superintendent of public instruction, the commissioner of insurance, the industrial commissioner, the labour commissioner, the commissioner of public safety, the superintendent of banking and the comptroller.

Much of the administrative work of the state government is performed by boards or commissions, usually bipartisan. Except for the commerce commission and the state board of public instruction, to which members are elected, membership on these boards is appointive. Among the other administrative boards are the state highway commission, the board of parole, the conservation commission, the board of control of state institutions, the Iowa development commission, the liquor control commission, the employment security commission, the real estate commission, the board of regents, the state tax commission and the department of social welfare.

The state legislature, called the general assembly, is composed of a senate and house of representatives which meets in odd-numbered years. Senators, who must be at least 25 years of age, are elected for a term of four years, one from each of the 50 senatorial districts, the terms of half of the members expiring every two years. Representatives are elected for a term of two years, one from each of the 99 counties, with an additional one from each of the counties (not exceeding nine) having the largest population. The ratio of representation and the apportionment of the additional representatives from the larger counties are fixed by the general assembly.

A judicial reform amendment providing for the first major reorganization of one of the three branches of the state's government since Iowa was admitted to the union in 1846 was approved by the voters in 1962 and went into effect in 1963. Following the so-called Missouri plan designed to remove judges from party politics (*see* MISSOURI: *Government*) the nine judges of the supreme court and the 71 members of the district court are appointed by the governor from a list of candidates prepared by nominating commissions. Supreme court members serve for terms of eight years (formerly six) but must be approved by popular vote after serving one year and, within one year of the expiration of their first term, must again be voted on for continuance in office; they do not run against other candidates. The same provisions apply to the members of the district court except that their terms are six years.

The supreme court has original jurisdiction in certiorari and mandamus cases, and appellate jurisdiction in cases sent to it from the lower courts. It also has the power to pass on the constitutionality of state laws. The district court has general, original and exclusive jurisdiction in all civil, criminal and probate matters not expressly conferred on an inferior court, and may hear appeals from inferior courts, boards or officers.

Each of the 99 counties has its own administrative boards and officers. The boards of supervisors consist of not more than seven members who are elected for three-year terms and have the care of county properties and the management of county business, including highways and bridges. The boards also fix the rate of county taxes within prescribed limits and levy the taxes for state and county purposes. Other county officers are: auditor, treasurer, clerk, recorder, sheriff, attorney, engineer, coroner, assessor and superintendent of schools.

Four cities, Camanche, Davenport, Muscatine and Wapello, were given special charters prior to 1857. Cities are of two types: those with a population of more than 15,000 and those with a population of from 2,000 to 15,000. All other incorporated places, except the special-charter cities, are classified as towns. Local adoption of the commission-manager plan of municipal government was authorized by the general assembly in 1915. Home rule legislation adopted in 1963 conferred on municipalities authority to act on local matters and powers of self-determination respecting internal affairs. Up to that time, the municipal governments were limited to those powers specifically granted to them by statute.

Finance and Taxation.—In 1929 a state tax commission was established for the purpose of centralizing the tax structure. Although the commission worked toward an integrated system, taxation has remained, in large part, a series of semi-independent levies. The tax sources for the state, with the percentage of total revenue in the second half of the 20th century, were: motor vehicle license, motor carrier and gasoline tax (38%); sales and use tax (34%); income tax: individual and corporation (13%); liquor profits and beer tax (5%); cigarette tax (3%); insurance premiums (2%); inheritance tax (2%); and miscellaneous taxes (2%). The state's revenue from all sources was about $350,000,000 annually. Of this amount, about one-sixth was derived from the federal government and about 70% from state tax sources. The state's expenditures totaled approximately $355,000,000, but there was no state debt. In the second half of the 20th century approximately 25% of the state's revenues was appropriated for education, nearly 38% was allocated to highways, more than 13% to public welfare and slightly more than 5% to health and hospitals. The state's income at this time was about three and one-half times as great as it had been prior to World War II; expenditures had increased at about the same rate. Iowa's per capita income ranked it 24th among the states in 1950 but it fell to 27th place toward the end of the next decade. It was only slightly below the national average, however.

Iowa has not levied a general property tax for the financing of the state government since 1941. There are, however, property taxes levied on a local level. This revenue is used primarily for schools, roads, municipal and county government and various local projects.

POPULATION

The population of Iowa in 1850, four years after it had obtained statehood, was 192,214. Its population ranked 27th among the 37 states and territories that then composed the union, and was classified as nearly 95% rural. The previous decade had been the period of the most rapid growth in Iowa's history—the population increased almost 346% from 1840 to 1850. At the beginning of the 20th century, the state had advanced to 10th in rank of population with a total of 2,231,853 persons by the 1900 census. The state was still largely rural in character: about three-fourths of the people were classified as nonurban dwellers. The next ten years saw an actual decline in the state's population—the 1910 census showed a drop of 0.3% from the census of 1900. The 1950 population indicated a total of 2,621,073 persons lived within the state, making it the 22nd in size of population among the states. The rural population was slightly more than 52% of the total at that time. Of the 1960 population, 1,462,512 or 53% lived in incorporated places of 2,500 or more, as compared with 46.9% in 1950, when these places constituted the urban area. The urban population, under a new definition set up in 1950, included also the thickly settled suburban area, or "urban fringe," adjacent to Des Moines, Sioux City, Davenport, Cedar Rapids, Dubuque, Waterloo and Omaha, Neb. (standard metropolitan statistical areas). By 1960 these areas housed 33.2% (915,762) of the total population. In 1960 Iowa had a population of 2,757,537, an increase of 136,464 or 5.2% over 1950, and ranked 24th in population.

The population per square mile in 1960 was 49, as compared

*Populations are reported as constituted at date of each census. †Name changed from Valley Junction in 1938.

Note: Dash indicates place did not exist during reported census, or data not available.

with 49.6 for the U.S. as a whole. By 1960 the urban population was increasing. Distribution by colour and nativity, according to the 1960 census, was as follows: 96.9% native white; 2% foreign-born white; and 1.1% nonwhite. Along with the rest of the U.S. the percentage of persons 65 years old or over was increasing, being 10.5% in 1960. The percentage of the population 14 years old and over that was in the labour force (54.3% in 1960) was steadily decreasing.

EDUCATION

History and Administration.—The first schools in Iowa were private. In 1830 a private school was opened in the Half-Breed tract, now Lee county. In 1834 free tax-supported schools were legally authorized for the area and by 1838 there were more than 40 schools established. When the Iowa territory was formed (1840) a law was passed defining the means of establishing free schools. The educational system has as its basis a law passed by the state legislature in 1858. Education was made compulsory by the general assembly in 1902. Since that time, legislation has extended the school year to at least 24 consecutive weeks for children between the ages of 7 and 16 unless they have completed the eighth grade or are over 14 and employed. In 1911 the legislature authorized large, centrally located, consolidated schools to replace small, scattered ones. Part-time schools for employed children between 14 and 16 were provided for in 1919. In the second half of the 20th century Iowa had the distinction of having the lowest percentage of illiteracy in the union. At that time, the state was spending $299 annually per pupil or slightly more than the U.S. average. This represented almost three times as much per pupil as had been spent prior to World War II.

At the head of the Iowa system of public schools is the state superintendent of public instruction, assisted by the state board of public instruction. The superintendent is, by law, the executive officer of both the board of educational examiners and the board of vocational education. The county administration is in the hands of a popularly elected board of five officers who, in turn, appoint a county superintendent of public instruction for a three-year term. Each school district has its separate board of education or trustees.

School revenue is derived from the state's permanent school fund, which grew out of land granted to the state by the federal government, and from local or district taxation.

Colleges and Universities.—Iowa has about 50 institutions of higher learning, which are governed by the state board of regents. This nine-member board is appointed for six-year terms by the governor with the approval of the senate. Schools supported by the state include the University of Iowa (Iowa City), Iowa State University of Science and Technology (Ames) and State College of Iowa (Cedar Falls).

The University of Iowa (formerly State University of Iowa) was established by an act of the legislature in 1847. Instruction was begun in the spring of 1855. The law department was added to the college of liberal arts in 1868, the medical department in 1870, the dental department in 1882 and the department of pharmacy in 1885. All these later became colleges. The graduate college was added in 1900 and the college of engineering in 1905. The school of education, created in 1907, became the college of education in 1913; and a school of commerce, established in 1914, became the college of business administration in 1959.

In addition to these nine colleges, a preparatory department was maintained from the founding date of the university until 1879; a homeopathic medical department, later a college, from 1876 to 1919; and a college of fine arts from 1911 to 1915. Within the college of liberal arts are the schools of fine arts, journalism, religion and social work. In 1949 the school of nursing became the college of nursing. The extension division was organized in 1913, the Iowa child welfare research station in 1917, the institute of hydraulic research in 1931, the institute of public affairs in 1949, the bureau of labour and management in 1950, the institute of gerontology in 1951, the institute of agricultural medicine in 1955 and the Iowa urban community research centre in 1958.

The central building of the university campus is the Old Capitol, which was turned over to the university when Des Moines became the state capital in 1857. The medical centre includes general, children's and psychopathic hospitals; the hospital-school for severely handicapped children; medical laboratories and the medical research centre.

Iowa State University of Science and Technology is the state land-grant college; the name was changed from Iowa State College of Agriculture and Mechanic Arts in 1959 at which time the following divisions became colleges: agriculture (established 1868), engineering (1868), sciences and humanities (1868), home economics (1872), veterinary medicine (1879) and graduate college (1919).

State College of Iowa at Cedar Falls was chartered as Iowa State Normal school in 1876 and was renamed Iowa State Teachers college in 1909.

Among the privately supported educational institutions in Iowa are: Briar Cliff college (Sioux City, Roman Catholic, 1930); Buena Vista college (Storm Lake, United Presbyterian Church in the U.S.A., 1891); Central college (Pella, affiliate of Reformed Church in America, 1853); Clarke college (Dubuque, Roman Catholic, 1843); Coe college (Cedar Rapids, affiliate of United Presbyterian Church, 1851); Cornell college (Mount Vernon, affiliate of the Methodist Church, 1853); Drake university (Des Moines, related to the Disciples of Christ, 1881); Grinnell college (Grinnell, nonsectarian, but related to Congregational Church, 1846); Iowa Wesleyan college (Mount Pleasant, affiliate of Methodist Church, 1842); Loras college (Dubuque, Roman Catholic, 1839); Luther college (Decorah, affiliate of Evangelical Lutheran Church, 1861); Marycrest college (Davenport, Roman Catholic, 1939); Morningside college (Sioux City, Methodist, 1889); Parsons college (Fairfield, affiliate of United Presbyterian Church, 1875); St. Ambrose college (Davenport, Roman Catholic, 1882); Simpson college (Indianola, affiliate of Methodist Church, 1860); University of Dubuque (Dubuque, affiliate of United Presbyterian Church, 1852); Upper Iowa university (Fayette, nonsectarian, 1857); Wartburg college (Waverly, American Lutheran Church, 1865); Westmar college (Le Mars, affiliate of Evangelical United Brethren Church, 1900); and William Penn college (Oskaloosa, Friends, 1873).

HEALTH AND WELFARE

The Iowa department of public health, established in 1924, is headed by a commissioner, who is required to be a physician with special training in public hygiene and sanitation. The department is concerned with the major causes of sickness and death, mental health and the prevention and control of communicable diseases. Major health programs are administered by the division of maternal and child health, the division of dental hygiene, the division of cancer control, the division of gerontology, heart and chronic diseases, the division of public health engineering and industrial hygiene, the division of public health nursing and the division of public health education.

The charitable, penal and reformatory institutions of the state are supervised by a board of control of state institutions which has three members appointed by the governor. The institutions include: a soldiers' home at Marshalltown; a school for feebleminded children at Glenwood; a hospital for epileptics and school for the feeble-minded at Woodward; four hospitals, or mental health institutes, at Clarinda, Independence, Mount Pleasant and Cherokee; a juvenile home for destitute, neglected or homeless children at Toledo; the Annie Wittenmyer home for children at Davenport; a training school for delinquent boys at Eldora; a similar institution for girls at Mitchellville; a men's reformatory at Anamosa; a women's reformatory at Rockwell City; and a state penitentiary at Fort Madison. The state also maintains a school for the deaf at Council Bluffs, one for the blind at Vinton and a combination school and hospital for handicapped children at Iowa City.

In 1907 the general assembly passed a law that established the indeterminate sentence for certain criminal offenders. The governor appoints a board of parole of three members, one of whom must be an attorney, and of which not more than two may be

members of the same political party. A bill calling for the sterilization of certain mental defectives was passed in 1929. The provisions of the bill are carried out by an ex-officio board of eugenics.

In 1937 a state department of social welfare was created to administer old-age assistance, aid to the needy blind, aid to the disabled (since 1950), child welfare and the care of dependent children and general relief in the state. The state board supervises the county boards of social welfare. The employment security commission manages a system of old-age and retirement insurance, which went into effect in 1946.

THE ECONOMY

Agriculture.—The superior quality of the soil and the warm, moist months of spring and summer make Iowa one of the foremost states of the union in the production of corn (maize), oats, hay and soybeans. Much of the produce is utilized in the further production of poultry, hogs, dairy cattle and sheep. Of the total farm acreage of approximately 35,000,000 ac., more than 60% was under actual cultivation in the second half of the 20th century. The average size of farms was about 185 ac., and the average value of farm land per acre was nearly $200. There was a pronounced trend toward larger holdings.

In the second half of the 20th century, cash receipts from farm marketings and government payments averaged more than $2,000,000,000 annually, more than $1,500,000,000 of which came from livestock and livestock products, and about $375,000,000 from crops of all kinds. Corn is the most important crop, and Iowa ranks first among the states in corn production with almost half the cultivated area of the state devoted to its culture. In the quarter-century after 1935 the total average annual yield was increased almost 400%. After corn, the most important Iowa crops are oats, barley, soybeans and hay.

By the second half of the 20th century the value of Iowa livestock was greater than that of any other state and twice as great as the valuation in 1920. Hogs, cattle, sheep and lambs are the principal types of stock raised. Dairy products and poultry are also vital parts of the state's agricultural program. The average egg production during 1950–60, for example, exceeded 4,000,000,000 eggs per year; Iowa farmers sold 1,500,000,000 lb. of whole milk annually in the same period and the state was first in the amount of cream sold.

Industry.—Although Iowa is famous for its agriculture, a considerable amount of industry has been attracted to the state by the Iowa development commission. During the second half of the 20th century Iowa industries employed more than 160,000 persons and paid more than $600,000,000 annually in salaries and wages. The estimated total value added by industry in a typical year of the 1950s was 3.81 times as great as that of 1929.

Most of Iowa's industrial plants are engaged in the processing of foods of various kinds. Meat-processing plants are the most important, the largest pork-processing plant in the United States being located in Iowa. Of secondary importance are dairy products-processing establishments and poultry-processing plants. Machinery manufactured in the state includes tractors, combines, corn-pickers and hay-balers. Printing and publishing are important industries. A large aluminum-rolling mill is located at Davenport and a leading manufacturer of fountain pens is at Fort Madison. Des Moines, Cedar Rapids and Waterloo are the state's leading industrial centres.

Mineral Production.—Iowa's first settlement was a mining camp, but this event proved to be no index to future mineral production. The early lead and zinc mines around Dubuque are little worked, and these products are of small significance in comparison with the state's total mineral output. During the second half of the 20th century, Iowa was among the first ten states in its production of gypsum and cement, but ranked 29th among the states in the value of all of its minerals.

Transportation.—From the close of the Civil War to 1920, the railroad was Iowa's most important means of transportation, although river traffic was of considerable importance during the 19th century. It was in those years that the "Big Four" railroads (the Chicago, Burlington and Quincy; the Chicago and North Western; the Chicago, Milwaukee, St. Paul and Pacific; and the Chicago, Rock Island and Pacific) established control over almost three-fourths of the railroad mileage (about 8,900 mi.) in the state. Since 1920, however, the railroads have steadily declined in favour of motor vehicles and airplanes.

Iowa has long had a state highway system, but it was not until 1919 that highways were classified as primary and secondary. In 1925 the state highway commission began its control of the primary road system. By the second half of the 20th century there were about 8,700 mi. of highway in the state primary system. Motor vehicle registrations increased from 437,000 in 1920 to more than 1,200,000 by 1960. Iowa was receiving about $35,000,000 in federal funds annually under the national highway program initiated in 1956.

The creation of the Iowa aeronautics commission by the general assembly in 1945 testified to the increasing importance of air travel. The number of licensed pilots increased from 1,882 in 1940 to more than 16,000 after World War II; more than 1,600 privately owned planes were registered with the aeronautics commission and there were more than 200 airports and five commercial airlines doing business in the state.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year,* American edition. (P. W. GL.)

IOWA, UNIVERSITY OF, an institution of higher learning, in Iowa City, Ia., was organized by an act of the legislature in 1847. *See* IOWA: *Education.*

IOWA CITY, a town on the Iowa river in east central Iowa, U.S., 57 mi. W. of the Mississippi river, the seat of Johnson county. Founded as the capital of Iowa territory in 1839 and incorporated as a town in 1853, Iowa City lost the state capital to Des Moines in 1857 but retained the state university and historical society. The university buildings, including the Old Capitol, now dominate the centre of the community. Iowa City was an important immigrant dispersal point during the late 1850s; from there in 1856 about 1,300 European Mormons proceeded to Utah, carrying their baggage in handcarts. Ohio, Pennsylvania and New York provided the largest number of early settlers, including Amish and Mennonite groups which in the mid-20th century still maintained their identities. By 1900 there were 2,622 Bohemians and Germans present and foreign born or their children made up 50% of the population; this proportion then declined. (For comparative population figures *see* table in Iowa: *Population.*)

Iowa City has a council-manager government, in effect since 1951. The residents mainly serve the needs of the state university, the university hospitals, a veterans hospital, Mercy hospital, Oakdale tuberculosis sanatorium and the hog, cattle and corn agriculture of the county. Aside from a toiletries plant and a brush factory there is little local industry. Lake Macbride State park and the Herbert Hoover birthplace lie to the north and east.

(A. G. Bo.)

IPECAC (IPECACUANHA), an expectorant and emetic, is obtained from the dried roots of *Cephaëlis ipecacuanha* (Rio or Brazil ipecac) or of *Cephaëlis acuminata* (Cartagena, Nicaragua or Panama ipecac). The former is indigenous to Brazil but also grows in Colombia, while the latter is obtained mainly from

Colombia and Nicaragua. Ipecac owes its emetic properties to the presence of the alkaloids emetine and cephaëline, which occur mainly in the cortical portion of the root. Ipecac is used in large doses as an emetic (it may be poisonous in excessively large doses) and in smaller doses as an expectorant and diaphoretic. The alkaloid emetine was formerly the mainstay in treating amoebic dysentery, but it has been largely replaced by synthetics and antibiotics.

IPHICRATES (*c.* 410–*c.* 353 B.C.), Athenian general, is chiefly known for the use he made of lightly armed troops (*peltastae*); he increased the length of their weapons and improved their mobility by reducing their defensive armour. He also paid special attention to discipline, drill and maneuvers. Iphicrates used his peltasts skilfully in the Corinthian War (394–386), and near Corinth he almost annihilated a battalion of Spartan hoplites in 390. Transferred to the Hellespont, he was equally successful. After the peace of Antalcidas (386) he assisted Seuthes, king of the Thracian Odrysae, to recover his kingdom and was sent with a force of mercenaries to assist the Persians to reconquer Egypt; but a dispute with the Persian commander Pharnabazus led to the failure of the expedition. On his return to Athens (373) he commanded an expedition for the relief of Corcyra, which was besieged by the Spartans. On the peace of 371, Iphicrates returned to Thrace and fought for the Thracian king Cotys in a war against Athens for the Chersonese. The Athenians, however, soon pardoned him and gave him a joint command in the Social War or "war of the allies" (357–355). He and two of his colleagues were impeached (perhaps in 354) by Chares, the fourth commander, because they had refused to give battle during a violent storm. Iphicrates was probably acquitted but died soon afterward.

IPHIGENIA, in Greek mythology the eldest daughter of Agamemnon, king of Mycenae, and of his wife Clytemnestra. Her father had to sacrifice her to the goddess Artemis in order that the Achaean fleet, of which he was leader, might be delivered from the calm (or contrary winds) by which Artemis was detaining it at Aulis and proceed on its way to the siege of Troy. Iphigenia is not mentioned in Homer.

As a member of the house of Atreus (*q.v.*) she shared in the unhappy fate of that family and is a key figure in certain Greek tragedies. In Aeschylus' *Agamemnon,* Clytemnestra uses her daughter's death as a pretext for murdering her husband. In Sophocles' *Electra* the reason for Artemis' detention of the Greek fleet is said to have been the shooting by Agamemnon of a deer belonging to her; she will not allow the fleet to move until Iphigenia has been sacrificed. Euripides' unfinished *Iphigeneia in Aulis* begins with Agamemnon's sending for his daughter on pretext of marrying her to Achilles but really in order to sacrifice her. Euripides' earlier play *Iphigeneia in Tauris* depicts Iphigenia in the land of the Tauri (the Crimean peninsula) as priestess of Artemis, having been rescued from sacrifice by the goddess, who substituted for her a deer. When her brother Orestes (*q.v.*) comes to carry away Artemis' image in order that he may be purified from the murder of his mother, Iphigenia saves him from having to be sacrificed and escapes with him to continue her service of the goddess in Attica. There, after her death, she is to be honoured (at Brauron) by offerings of garments of women who have died in childbirth. Variants of her story are found in later authors. In some localities she was identified with Artemis; Pausanias says that in Hermione (Argos) Artemis was worshiped under the name of Iphigenia. He also claims that Iphigenia was originally the goddess Hecate.

Iphigenia's story found favour with later European dramatists, providing the plot of Racine's *Iphigénie* and of Goethe's *Iphigenie auf Tauris.* Racine's play was the basis for the opera *Iphigénie en Aulide* by Gluck, who also composed *Iphigénie en Tauride.*

I-PIN (SUI-FU; SÜCHOW), a Chinese river port at the junction of the Min and Chin-sha (upper Yangtze) rivers in southwest Szechwan (Ssu-ch'uan) province and head of navigation to small steamers on the Yangtze. Pop. (1953) 177,500. It is the site of the Yangtze river crossing for the railroad to Yünnan in the south. A highway runs northward to the salt centre of Tzekung (Tzu-kung). With its transportation facilities, I-pin acts as the collection centre and export port for products of the Yünnan and Tibetan uplands, such as medicinal herbs and extracts, musk and metals, and as the dissemination point for salt, cotton and other manufactures to the surrounding mountain peoples. It is the nearest large city to the Liang-Shan Yi Autonomous district inhabited by Yi (Lolo) tribesmen (*see* also YI). Lac produced by the exudation of a species of insects feeding upon the twigs and young branches of trees is collected at I-pin from the Lo-shan (Chia-ting) region up the Min. (H. J. WS.)

IPIRANGA, GRITO DO, the "cry of Ipiranga" (Ypiranga), so-called because Brazil's independence was proclaimed at this place by Dom Pedro on Sept. 7, 1822. Sentiment for independence had been growing since the preceding year when King John VI returned to Lisbon, leaving his son Pedro as regent. When the Portuguese parliament limited the powers of the regency, the action was interpreted as an effort to reassert Portuguese rule in Brazil. A messenger sent to intercept the young regent returning to the capital from São Paulo met him on Ipiranga hill, where he vowed: "Independência ou morte!" (Independence or death!). He was proclaimed Pedro I (*q.v.*), emperor of Brazil, Oct. 12, 1822. (R. E. P.)

IPOH, capital of Perak state, Malaya, in the Federation of Malaysia, is on the Kinta river (*q.v.*), a tributary of the Perak, 110 mi. N.N.W. of Kuala Lumpur and 75 mi. S.E. of George Town. Pop. (1957) 125,770. Steep hills rise within a few miles on all sides except the south. The flat alluvial plain around Ipoh which has been repeatedly churned over by tin mines produces more than half of Malaya's output, making Ipoh effectively the mining capital of the country. The town dates from the end of the 19th century, when the smaller tin fields around Taiping lost significance and British companies, using immigrant Chinese labour, transferred to the rich Kinta ores. At that stage the tin concentrates were taken down the Kinta river but the railway was soon extended from Taiping to Ipoh linking with Penang. No smelting is done in or near Ipoh. Beneath the mines is a limestone structure riddled by solution, and east of the town limestone rocks rise through the alluvium with gigantic caves which are used as Chinese temples, and at times as hideouts for outlaws.

Ipoh has the spacious rectangular layout of a modern pioneer township. A high degree of electrification has been achieved in the town by the use of diesel generators and hydroelectricity from the Chenderoh dam on the Perak river. In addition to the tin, rubber from foothill plantations is also marketed. The town is dominated by Chinese of the Hokkien and Hakka communities, and its suburbs have spectacular residences of wealthy miners. Ipoh is the most important station on the Kuala Lumpur-Prai railway and is the focus of a series of main roads across the Kinta valley, north of Penang and south to Kuala Lumpur. Air services also operate to Penang, Kuala Lumpur and Singapore. *See* also PERAK. (E. H. G. D.)

IPOMOEA, a large genus of mainly climbing herbs or shrubs of the morning-glory family (Convolvulaceae; *q.v.*). It includes the sweet potato, morning-glory (*qq.v.*) and manroot.

IPPOLITOV-IVANOV, MIKHAIL MIKHAILOVICH (1859–1935), Russian composer of instrumental music, operas and songs, was born at Gatchina on Nov. 12, 1859. In 1875 he entered the St. Petersburg conservatory as a composition student, where he studied, during his last two years, under Rimski-Korsakov; on leaving the conservatory in 1882 he went to Tbilisi (Tiflis) where he founded and conducted regular symphony concerts and directed a music school. In 1893 he joined the staff of the Moscow conservatory, of which he was director from 1906 to 1922; until 1906 he had also been conductor of Mamontov's opera company in Moscow, giving some notable first performances. In 1924–25 he visited Tbilisi to reorganize the Georgian state conservatory, which had developed from his former music school, but returned to Moscow in 1925 as director of the Bolshoi theatre. He died there on Jan. 28, 1935. Ippolitov-Ivanov's 11 years in the Caucasus led to a lifelong interest in Georgian folk music and inspired some of his most successful orchestral compositions: an *Armenian Rhapsody,* the symphonic poem *Mtsyri,* and five suites, of which the first (*Caucasian Sketches,* op. 10) won widespread popularity.

None of his six operas has held the stage, nor has his completion of Mussorgsky's *Marriage*.

See S. Bugoslavsky, *M. M. Ippolitov-Ivanov* (1936). (G. Ab.)

IPSUS, BATTLE OF (301 B.C.), called "the battle of the kings," was the culmination of a decisive campaign in the struggle between Antigonus I Monophthalmus, king in Asia Minor, and the other "successors" (*Diadochi*) of Alexander the Great. The battle, which resulted in the defeat and death of Antigonus, is memorable above all for its political consequences: the irrevocable dismemberment of the empire of Alexander and the disappearance from it of the last traces of a central authority.

The campaign was precipitated by the onslaught launched in 302 in northern Greece against Cassander, king of Macedonia, by Antigonus' son Demetrius Poliorcetes. When Cassander sued for peace Antigonus demanded his unconditional surrender. Unwilling to comply with these terms, Cassander sent his ally Lysimachus, king of Thrace, to invade Asia Minor, and arranged for Ptolemy of Egypt and Seleucus of Babylon to invade the other parts of Antigonus' kingdom from the south and east. Demetrius was forced to evacuate Greece and sail to his father's aid. In the summer of 301 Seleucus and Lysimachus joined hands and their combined forces faced the army of Antigonus and Demetrius at Ipsus in central Phrygia (the site cannot be identified precisely). Antigonus had 70,000 foot, 10,000 horse and 75 elephants; the allies 64,000 foot, 10,500 horse and at least 400 elephants. The large number of elephants which Seleucus had brought from India proved invaluable. Demetrius routed the opposing cavalry but pursued too far and was separated from the main battle by the enemy's elephants. Antigonus' infantry made but a poor resistance, many deserting, and Antigonus was killed, crying vainly, "Demetrius will come and save me." (R. H. Si.)

IPSWICH, a city of Queensland, Austr., lies on the Bremer river 24 mi. W. of Brisbane by rail. Pop. (1961) 48,679. Ipswich is the centre of an extensive farming, mining and manufacturing district. Coal mines within the municipal area produce about 1,500,000 tons annually and employ about 2,000 men. Another 3,500 are employed in the state railway workshops. Other industries include woolen mills, sawmills, foundries, hardboard manufacture and a butter factory. The first settlement, known as Limestone, was established in 1829. Renamed in 1843, Ipswich was incorporated as a municipality in 1860 and proclaimed a city in 1904. (V. N. S.)

IPSWICH, a county and parliamentary borough and the county town of Suffolk, Eng., lies 72 mi. N.E. of London by road. Pop. (1961) 117,325. It is an ancient market town and port at the head of the Orwell estuary and a farming and industrial centre. A large Roman villa site and an extensive pagan-Saxon cemetery of the 6th century on the right bank of the river Gipping have been found. A big kiln site in the eastern part of the town where first Ipswich ware, and later Thetford ware, were manufactured continuously from the 7th to the 12th centuries shows that Ipswich remained an important trading centre throughout the period in spite of the Danish settlements of the late 9th century and the sack of the town by the Vikings in 991. It prospered as the export town for the East Anglian cloth industry from medieval times until the mid-17th century. In 1200 King John granted the town its first charter, and it was incorporated in 1446. With the decline in the cloth trade the town suffered a setback, but the manufacture of agricultural machinery in the late 18th century paved the way for an industrial expansion in the mid-19th century.

Christ Church mansion (16th century), standing in a park, is an art gallery and museum; Sparrowe's, or the Ancient house, dating in part from the 15th century, has a fine 17th-century pargetted façade; Wolsey's gateway (*c.* 1529) is the only remnant of the cardinal's foundation that once supplied scholars to his great college (Cardinal's college, now Christ Church) at Oxford. The older churches are all towered flintwork structures, wholly or mainly Perpendicular in style, except in St. Peter's which is principally Decorated, with a Norman font of Tournai marble. Ipswich was the birthplace of Cardinal Wolsey, and from 1747 to 1759 Thomas Gainsborough lived and painted there. Ipswich school, founded in the 15th century, was refounded by Queen Elizabeth I in 1566. There is an Anglican bishopric of St. Edmundsbury and Ipswich. Several old coaching inns survive, including the "Great White Horse" of *Pickwick Papers* fame. Ipswich harbour extends 11 mi. downstream to Shotley point, and the dock commissioners control about 6,000 ft. of quayage, including a wet dock and a deep-water quay. Principal imports are coal, petroleum, grain, chemicals (for fertilizers), timber, roadstone and general cargo. Exports are barley, coke-breeze, malt and fertilizers. Beside agricultural machinery, Ipswich is also well known for the manufacture of lifting, excavating and irrigation equipment, fertilizers and cigarettes. Other industries include milling, malting, printing, clothing and textiles.

Ipswich Ware.—A type of middle Saxon pottery turned on a slow wheel with simple everted rims, sagging bases and extensive knife trimming at the base, was manufactured between the 7th and 9th centuries in kilns found at Ipswich. Widely distributed along the coast of East Anglia from the Wash in the north to Bradwell-on-Sea in Essex, it is derived in part from local pagan-Saxon ware, but the sagging bases and knife trimming indicate Rhineland influences.

Thetford Ware.—A type of late Saxon pottery first identified at Thetford in Norfolk and found widely distributed in Lincolnshire, Cambridgeshire, Norfolk, Suffolk and Essex, was manufactured between the 10th and 12th centuries. It succeeded Ipswich ware, of which it is a more sophisticated type, and is turned on a fast wheel. Kilns have been found at Ipswich on the same site as Ipswich ware kilns.

See J. G. Hurst and S. E. West, "Saxo-Norman Pottery in East Anglia," *Proceedings of the Cambridge Antiquarian Society*, 2:29–60 (1957). (D. Cx.)

IPSWICH, a town of Essex county, eastern Massachusetts, U.S., 28 mi. N.N.E. of Boston, on both sides of the Ipswich river and fronting on Ipswich bay. (For comparative population figures *see* table in Massachusetts: *Population;* there are in addition about 2,000 summer residents.)

The town was settled under the name of Agawam in 1633 and was incorporated in 1634 as Ipswich, being named for the English town. During the early days of the colony it was little inferior to Boston in wealth and influence, and frequently took an opposing position on public questions. Ipswich was the home of several of the leading writers of the colonial period, including Nathaniel Ward (1578–1652) and Anne Bradstreet (1612–72). Nearly 40 houses built before 1725 are still standing. The John Whipple house (1640) contains the collection of the Ipswich Historical society. The Choate bridge, built in 1764, is the oldest stone arched bridge in the U.S.

Ipswich has a selectmen-executive-secretary form of government in effect since 1955. (K. S. T.)

IQBAL, MOHAMMED (1877–1938), Indian Muslim poet and philosopher who sought to arouse the Muslim peoples to a new sense of their destiny, was born at Sialkot on Nov. 9, 1877. He studied law and philosophy in the Punjab and in Europe, and taught for a time at Government college, Lahore. He was knighted by the British government for excellence in literature (1922), was elected by the Punjab legislative assembly (1927) and was president of the annual session of the Muslim league (1930). He died in Lahore on April 21, 1938.

The recurrent themes of Iqbal's Urdu and Persian poetry are a memory of the vanished glories of Islam, a complaint about its present decadence and a call to unity and reform. Reform can be achieved by strengthening the individual, through three successive stages: obedience to the law of Islam, self-control and acceptance of the role of the vicegerent of God (*na'ib* or *momin*). A life of action is preferred to ascetic resignation. Iqbal's thought was influenced by Jalal-ud-Din Rumi, J. M. E. McTaggart, Nietzsche and Bergson. He attempts to rescue Islam from the grip of fatalism (*qismat*) by safeguarding man's freedom. In his *Asrar-i Khudi* (Eng. trans., *Secrets of the Self*, by R. A. Nicholson, 2nd ed., 1940) he says that God is as the soul in the body of the universe; God knows the future as potentiality and not as a predetermined actuality, the universe being still in the course of formation with man sharing in God's creative activity. In *The Reconstruction of*

Religious Thought in Islam (1934) he urges that in social ethics Islam must free itself from worn-out tradition and revive the right to interpret the law (*ijtihad*), so that each generation may solve its own problems guided by the work of its predecessors. Iqbal tended to be progressive in adumbrating general principles of change but conservative in initiating actual change. Earlier a supporter of Pan-Islam, he later realized the impossibility of this ideal. He is considered by many as the author of the Pakistan concept. His other works include *Ramuz-i Bekhudi* (Eng. trans., *The Mysteries of Selflessness*, by A. J. Arberry, 1953) and *The Development of Metaphysics in Persia* (1908).

BIBLIOGRAPHY.—I. Singh, *The Ardent Pilgrim* (1951); S. A. Vahid, *Iqbal* (1944); A. Schimmel, *Gabriel's Wing* (1963). (H. J. S.)

IQUIQUE, a city and port of Chile, capital of the province of Tarapacá (*q.v.*), 75 mi. S. of Arica and 820 mi. N. of Valparaíso. Pop. (1960) 51,468 (mun.). The Pacific coast runs due north and south and the city is built on a narrow level plain between the sea and bluffs, the latter rising steeply 2,000 ft. to the level of the desert plain of Tarapacá, celebrated for its rich deposits of nitrate of soda, which gives way to the Atacama desert (*q.v.*). Facing the city is the low barren island of Serrano, which is connected with the mainland by a stone causeway 1,500 ft. long and shelters the anchorage from southerly storms. A mole extending from the northeastern end of the island affords further protection.

The city is laid out on the rectangular plan, with broad streets and large squares. Water is brought by pipes from the oasis-town of Pica, 50 mi. inland. Iquique is a city of commercial importance and is provided with banks, substantial business houses, newspapers, clubs, schools, railways, tramways, electric lights, telephone lines and steamship, air and cable communication with the outside world. It exports iodine and immense quantities of nitrate of soda obtained from the adjacent desert region.

A large number of vessels are engaged in the nitrate trade, and Iquique ranks as one of the two leading ports of Chile in the aggregate value of its foreign commerce. It is connected by rail with the inland town of Tarapacá and various mining centres, and through them with the ports of Pisagua on the north and Patillos on the south.

Iquique was an insignificant Peruvian fishing settlement until 1830 when the export of nitrate began. In 1868, the town was nearly destroyed by an earthquake, in 1875 by fire, and again, in 1877, by earthquakes, a fire and a tidal wave. It was occupied by the Chileans in 1879 in the war between Chile and Peru, and was ceded to Chile by the treaty of Oct. 20, 1883.

IQUITOS, Amazon river port in northeastern Peru, and capital of Loreto department, 2,300 mi. upstream from the Atlantic ocean, is 640 mi. N.N.E. of Lima. Pop. (1961) 55,696. Located 3° 45′ S. at an elevation of about 350 ft., the climate is equatorial with an average rainfall of 103 in., but temperatures are not so high as in the middle latitudes—the warmest month (February) averages 78.3° F., and the coldest month (July), averages 74.1° F. The humidity is high, especially in the early morning hours.

Iquitos was founded as a Peruvian settlement in 1863 at a place occupied previously by an Indian village. The Peruvians became interested in the region during the rubber boom of the late 19th century, and Iquitos became the chief shipping port for this part of the world. In spite of the great distance from the Atlantic, ships drawing 14 ft. can reach Iquitos even at low water. The most prosperous period of rubber production was between 1906 and 1912, after which production dropped to only a fraction of what it had been. Population declined and for a long time this remote jungle region and the city which was its commercial centre remained stagnant.

Since 1950 there has been a renewed interest in the economic development of eastern Peru. Highways from Lima, including the Lima-Pucallpa highway, reach navigable water east of the Andes, and airplanes make the trip over the mountains in a few hours. Iquitos has started to grow again in response to the increased settlement and production in its tributary area. The products, most of which continue to move out by steamer, include small amounts of rubber, balata, chicle, medicinal plants, tagua nuts, cabinet woods, cotton, rice, coffee, tobacco and hides. (P. E. J.)

IRAKLION (HERAKLEION or CANDIA), the largest city in the Greek island of Crete, lies on the north coast, northeast of the central Mt. Psiloriti (Ida), and derives its name from the ancient Heracleum which probably occupied the same site. Pop. (1961) 63,458. The town gained much importance as a trading centre after the construction of the new harbour, the airport and a number of motor roads. The chief exports are grapes, sultanas, olives and olive oil, wine, carobs, citrus fruit, almonds, soap and leather.

The Saracens, who captured Crete between 823 and 828, made the city their capital, but they were defeated and massacred in 961 by Nicephorus II Phocas. In 1204, after the capture of Constantinople by the crusaders, Crete was sold by Boniface, marquis of Montferrat, to Venice, but was occupied by the Genoese and only became Venetian territory in 1210. Most of the extensive Venetian walls of Iraklion still survive.

In 1669 the city was ceded to the Turks after a long siege. Francesco Morosini, later doge of Venice, commanded the defenders, and the finely sculptured fountain he erected still remains, though his loggia was pulled down and the surviving Venetian churches desecrated. There is a modern cathedral, Armenian and Roman Catholic churches and also the interesting old church of St. Menas. A modern museum contains the finest collection in the world of Minoan antiquities from Knossos, 3 mi. S.E., and from other Cretan sites, and there are interesting remains of later dates in the new historical museum. The Turkish mosques have been destroyed or converted to other uses. A monument commemorates Dhaskaloyannis, flayed alive there after the rebellion of 1770.

In a massacre that followed the Cretan rebellion (1897) 17 British sailors were killed there, and Adm. Sir Gerard Noel forced the Turks to surrender the city. With the rest of Crete, after a period as a protectorate, Iraklion passed to Greece in 1913. During the German invasion in 1941 the city suffered heavily from aerial bombardments.

Iraklion is the capital of a *nomos* (department) of the same name; this department consists of the hilly country round Mt. Iouktas on the east and the valley of the Kairatos on the west, opening out into a coastal plain, perhaps the most fertile land in Crete except that of Mesara. *See* also CRETE. (R. W. HU.)

IRAN (PERSIA), a kingdom of western Asia bounded north by the U.S.S.R. and the Caspian sea; east by Afghanistan and Pakistan; south by the Persian gulf and the Gulf of Oman; and west by Iraq and Turkey. The total area is 636,295 sq.mi. and the length of the frontiers about 2,750 mi. Teheran is the capital. In 1935 the Iranian government asked foreign governments to use "Iran" as the name of the state instead of "Persia" (*q.v.*). Although on Oct. 25, 1949, the Iranian government stated that it would no longer insist on this, "Iran" remained in common use.

Frontiers.—The frontier with the U.S.S.R. is that laid down in the treaty of Turkmanchai (1828), further defined in a convention of July 8, 1893, and modified in minor details in 1951. The Afghan frontier was defined in 1881 and in the convention of July 8, 1893. From the Siah Kuh river to Kuh-e Malek Siah (the junction of the Afghan, Pakistan and Iranian borders) it follows a line fixed by Sir Frederick Goldsmid in 1872 and by Sir (Arthur) Henry MacMahon in 1903–05. The southern boundary is the coast line from Gavater to the mouth of the Shatt al Arab. Iranian territory also includes the islands of Hormuz, Larak, Qeshm (Qishm), Hengam, Forur, Qais, Hendorabi, Sheykh Sa'd, Sheykh Sho'eyb, Khark and Kharku. There are also Iranian claims upon the territory of Bahrain. The frontier with Turkey extends from the Little Ararat to meet the Iraqi boundary at Kel-e-Shin. From that point the frontier line with Iraq extends about 550 mi. to the Shatt al Arab; it then follows the low water line to the mouth of the river and includes the anchorages of Khorramshahr (Mohammerah) and Abadan (*qq.v.*). This line was established by an international commission by the treaty of Erzurum (1847), demarcated in 1914 and reaffirmed by an agreement between Iraq and Iran in 1937.

I. PHYSICAL GEOGRAPHY

1. Geology.—What knowledge of the geology of Iran existed prior to the search for oil is contained in the work of A. F. Stahl (1911). Later, systematic exploration was carried out by the former Anglo-Iranian Oil company (A.I.O.C.) in the southwest and, after 1951, by the National Iranian Oil company (N.I.O.C.) over most of the country. In 1959 the N.I.O.C. published the first comprehensive geological map of Iran in which all existing knowledge appears to be synthesized.

The Iranian upland, of which Iran occupies the western two-thirds while the remaining part belongs to Afghanistan and Pakistan, is an important section of the Alpine-Himalayan fold mountain system. It forms a great loop, the border ranges converging in the northwest and northeast. Theories of a symmetric arrangement of folds and nappes on both sides, north and south, of a stable central (median) mass have proved to be wrong. The rocks, formerly mistaken for the base, were those metamorphosed during an early Cretaceous orogeny.

Thick red and green shales in the Kuh-e Dinar and elsewhere in the Zagros mountains are of Cambrian Age, and the rock salt with various components of the Hormuz and Ravar series in the south and east may be coeval or even older. Old Red Sandstone is widely found in northwestern, northern and eastern Iran. It turned into thick, black carboniferous limestone when the country was covered by the Tethys sea. Marine sedimentation went on in Triassic time but in two or three different facies. During the Lower Jurassic period about 10,000 ft. of detrital material with intercalated coal seams were deposited over most of Iran. This was largely metamorphosed in central Iran during a marked pre-Middle Cretaceous diastrophism. The resulting land surface was not covered until the Middle Cretaceous, while in the Elburz, Kopeh Dagh and Zagros geosyncline marine sedimentation continued, with various breaks, through Upper Jurassic and Cretaceous times through to the Eocene and Oligocene periods. The Eocene deposits are mainly limestone in the Zagros region, with a tuffaceous formation containing basic lava flows ("Green Series") in the Elburz, and a thick type of flysch in east and southeast Iran.

The existence of the Central Iranian basin is proved in the Oligocene period from the occurrence of the lagoonal Lower Red formation. It was again intruded by the southern sea during the deposition of the oil-bearing Asmari limestone, but was re-established as a closed basin in the Upper Miocene when up to 15,000 ft. of salty marls and clays (Upper Red formation) were deposited corresponding with the Fars formation of the southwest.

Irrespective of various older orogenic movements the main molding of the Iranian mountain ranges occurred during the Pliocene and even later, as tilted Bakhtiari conglomerates, raised gulf beaches and active fault lines demonstrate. Autochthonous folding is juxtaposed on thrusting. The prevailing strike is northwest–southeast or west–east, but strong meridional components are found in the east. Fracturing has also been a factor in determining the topography.

An additional element was brought in by the Plio-Pleistocene volcanism in Azerbaijan (Kuhha-ye Sabalan, Kuh-e Sahand), Elburz (Mt. Demavend), Kerman (Kuh-e Hazaran, Kuh-e Laleh Zar) and Baluchistan (Kuh-e Taftan, Kuh-e Bazman). Salt domes of different ages are widespread in the Persian gulf area and in central Iran.

2. Relief and Drainage.—Most of Iran is an upland which consists of a central plateau and a high mountainous fringe marking it off from surrounding lowlands. The fringing mountain chains are of considerable width in the west and southwest, called Zagros, and from an average elevation of 8,000–10,000 ft. rise to 12,000–13,000 ft. in several places. The northern fringe is narrow in its western part (Elburz mountains [*q.v.*]), but includes the highest elevations in Iran (Mt. Demavend [*q.v.*] 18,580 ft., Alam Kuh 15,865 ft.). The eastern, Khurasan, section is a double chain on both sides of a wide vale. The interior is an immense plateau made up of wide valleys and depressions separated by low ridges and protracted mountain ranges, mostly running in a northwest–southeast direction. In the east, a north–south direction interferes and thus separates the Iranian from the Afghan-Baluch plateau. Valleys and depressions generally lose in elevation from the northwest to the southeast, descending from about 4,000–6,000 ft. to 1,500 ft. and even less than 1,000 ft. The largest depressions are the Dasht-e Kavir, southern Dasht-e Lut, the Jaz Murian basin, and the Isfahan-Sirjan valley. The most important interior range runs from south of Qom past Yazd and Kerman into the Sarhad-e Bala.

The main contrast is between the dry, desert interior and the humid outward fringes which receive the bulk of all precipitation in Iran. The permanent rivers originate in the higher massifs of this outward fringe. They also bear, with some remarkable exceptions, the main divide between the closed interior basins and the outward drainage. Important rivers of the northern slopes are the Aras (*q.v.*), Safid Rud (*q.v.*; which, with its main branch, Qezel Owzan, completely separates the catchment basin of Lake Reza'iyeh, or Urmia [*q.v.*], from the main basin of Iran) and the Atrak; of the western and southwestern slopes the Karkheh, Dez, Karun and Mand; of the interior the Qareh Su of Saveh, Rud-e-Qom, Zayandeh Rud of Isfahan, Kor, Kalshur of Birjand, and Kalshur of Khurasan. There are a great number of seasonal and episodic streams. Any runoff within the interior basins which escapes infiltration and evaporation is gathered in salt lakes (like Urmia or Bakhtegan [Niriz]) or in salt marshes (*kavir*), the surface conditions of which change widely from season to season.

The lowlands possessed by Iran are insignificant in area in the north (the Caspian coast, the Moghan and Atrak steppes) but more extensive in the south (the Khuzistan plain, the gulf coast).

3. Climate.—The climate is subtropical and continental in character. The summer is long, hot and, except for the humid coastlands, extremely dry. Northern winds prevail. Teheran (4,000 ft.) has a July mean temperature of 29° C. (84° F.). Daily maxima reach 43°–46° C. (110–115° F.) in July and August, but nights are mostly cool. Above 6,000–7,000 ft. the summers are pleasant, and the Iranians call this zone *sardsir*, or the cool land; it attracts in summer not only the flocks but also many people from the hot regions, especially the southern lowlands (the *garmsir*,

or warm land), which suffer from fierce heat. Ahvaz in July and August has mean temperatures of 38° C. (100° F.) with maxima exceeding 49° C. (120° F.). The gulf ports are slightly cooler but most of the time are oppressively humid.

The transitional seasons are normally short. Autumn is especially agreeable on the plateau while spring is delayed, cool and wet in the northern and western uplands. In winter there is an inflow of cold, dry air from central Asia through the gaps of Khurasan. Other sources of intensely cold air are the northwestern plateaus. Azerbaijan is probably the coldest province (the January mean temperature at Tabriz, 4,600 ft., is 29° F., with a minimum well below 0° F.). Frost, often severe, is experienced everywhere except in the *garmsir*, up to 4,000 ft.

In winter wandering depressions bring in mild and humid air from the Mediterranean eastward over Iran, and the clash of the air masses causes heavy snowfalls in the north and west and rainstorms in the south. Precipitation in the south is strictly limited to the winter while in the northern and western uplands rain falls until April and even May. These are the regions where cultivation is feasible upon rainfall alone. They usually receive over 12 in. whereas the higher parts of the Zagros receive 20–30 in. The Caspian slopes of the Elburz have an annual rainfall of more than 40 in., the Khurasan ranges barely 20 in. The lowest of the arid interior basins, the Great Kavir, Lut and Seistan, receive less than 4 in. Irregularity of rainfall through the years is extraordinary in most parts. It varies at Teheran from 4 in. to more than 20 in. and at Bushire (*q.v.*) from below 2 in. to more than 26 in. Permanent snow and glaciers can be found on the highest summits in the Elburz and Zagros mountains. Elsewhere the thaw begins in March or April, freeing the pastures for the annual migration of the pastoral tribes and filling the streams with water for irrigation.

4. Vegetation.—There are more than 10,000 known plant species in Iran of which a great number are endemic. Four main floristic regions can be discerned: two are natural forest areas, covering the northern and western façades of the upland; the other two are more or less open steppe and desert. All the natural vegetation types have suffered destruction from use and misuse by man and his flocks through the ages, and it is difficult to determine the true natural conditions.

The Hyrcanian forest on the Caspian coast, where rainfall is abundant, is almost tropical in appearance with its tall, creeper-covered, deciduous trees. It contains several relics of the Late Tertiary European forest including Caucasian wingnut (*Pterocarya fraxinifolia*) and Caspian honey locust (*Gleditsia caspica*). The northern slopes of the Elburz are clothed in forests in which oriental beech, oak, hornbeam, maple, ash and elm predominate; the conifers are represented only by the yew. The remains of a dry forest cover the outer slopes of the Zagros ranges. It is made up of oak, maple (two endemics are *Quercus brantii* or *Quercus persica* and *Acer cinerascens*) and a variety of other trees. There are many Mediterranean intrusions below 6,000 ft. This forest reaches from the Turkish frontier southeastward to Shiraz and farther, but is not found on the western foothills.

The interior plateau and mountain ranges belong to the Irano-Turanian type of vegetation. The steppe, dense where the rains are adequate, contains mainly low shrubs with herbs like *Salvia*, the composite *Cousinia*, giant fennel (*Ferula*). Spiky cushions of *Astragalus* and prickly thrift (*Acantholimon*) dominate above 8,000 ft. Wormwood (*Artemisia*) is widespread at lower altitudes. It gives way to camel's thorn (*Alhagi camelorum*) in the semideserts where also tamarisk replaces poplar and willow along the river beds. Halophytes occupy the salty districts, saxaul the sands. The southern slopes of the Elburz and the Khurasan ranges were once covered with sparse forests of juniper and even in the true desert were loose stands of wild pistachio, almond and other bushes. Thin forests of these shrubs with maple and juniper covered the interior slopes of the Zagros and the higher ranges of Laristan and Kerman.

In the southern *garmsir* Saharo-Sindian elements intrude and even characterize the steppe or semidesert vegetation. There are thin stands of konar (*Zizyphus spina-christi*), kahur (*Prosopis spicigera*) and acacia trees. A dwarf palm exists in Baluchistan. But most characteristic of this region is the date palm which is cultivated in every oasis.

5. Animal Life.—Detailed knowledge of the animal life in Iran is incomplete. The position of the country at the crossroads of three continents (plus the Indian subcontinent) led to the immigration of many species. However, endemism is pronounced. There are more than 100 species of mammals known, of which about 18% are endemic. The lion (the national emblem of modern Iran) is now extinct. A few tigers may exist in the Caspian forests, while panther and wildcats are fairly common. Cheetahs, jackals, wolves, foxes, hyenas, brown bears and wild boars are widely distributed, as are a great number of rodents. Jerboa, mongoose, Persian squirrel and Indian crested porcupine occur in suitable localities. Wild sheep (mouflon) and ibex are still common on mountain ranges, while the Persian gazelle roams the steppe and the wild ass the desert.

In addition to a large number of resident birds, including many European species, others visit Iran to breed or to winter. More than 320 species are known in the Caspian lowland. Game birds are numerous including partridge, sand grouse and snipe. Many varieties of duck visit Iran in winter; swans and geese are found on the Caspian coast and in Seistan. Large numbers of pelicans and flamingos breed on the southern lakes and on the shores of the Persian gulf. Various types of owl are found and also falcons, buzzards and kestrels; eagles are fairly common.

Most of the rivers are too variable in flow to contain a wide variety of fish. The chub, barbel, trout and catfish are found in the Elburz rivers. The Caspian sturgeon and salmon are of special importance. Various carp live in the rivers of the south. The waters of the gulf and of the Makran coast contain a great variety of fish. Among the amphibia, the Greek tortoise is common except at high altitudes. The agamids are the commonest lizards. the waran reaching more than three feet in length. Snakes and vipers (many poisonous) are also common.

II. GEOGRAPHICAL REGIONS

The obvious division of the country is into plateau and bordering mountain ranges in the north and south. Azerbaijan, the eastern borderlands and the Khuzistan plain form separate units.

Azerbaijan.—This is an area of faulted blocks and basins, largely drained toward the shallow and salty lake of Urmia while the remainder is drained by the Aras, Little Zab, and Qezel Owzan. Geographically the region forms a transition between eastern Anatolia, Transcaucasia and the Persian interior, and has served as a crossroads and battlefield throughout history. Great volcanic cones, *e.g.*, Kuhha-ye Sabalan, 15,000 ft., are a distinctive feature and are associated with the fault system. The winters are bitterly cold and snowy, the summers hot and almost arid. The plateaus afford good grazing, a fact that attracted the Mongols and still supports nomadism (Kurdish and Shahsevan tribes). The plains round Lake Urmia are well irrigated and densely populated. Tabriz, 35 mi. from the marshy shores of Urmia, is a great market and route centre, and the second city of Iran. (*See* also AZERBAIJAN.)

Zagros Mountains.—These are of the Jurassic type; *i.e.*, numerous parallel ranges and valleys corresponding closely to the underlying fold structure. They form a belt 875 mi. long from the borders of Azerbaijan to northeast of Bandar Abbas and up to 200 mi. wide. The ranges, of moderate elevation in the north, are tightly packed and lofty (14,000 ft.) in the central section between the Dez valley and northwest of Shiraz, spread out again in southern Fars and Luristan. Heavy winter snows and many springs maintain perennial streams. These issue through *tangs* (narrow defiles) to the western lowlands. Together with the steep ascents, these gorges make routes extremely difficult. In spite of signs of formerly more intense settlement and cultivation in many valleys, the country is now almost exclusively pastoral with seasonal migration between lowland and upland. The chief population centres are on the few old-established cross routes; *e.g.*, the Kermanshah route between Baghdad and Teheran and the Shiraz route from Bushire. There is a modern road through Khorramabad, while the

Trans-Iranian railway uses the Dez gorge. Oil occurs in the shallow anticlines along the southwestern foothills, the reservoir rock being the Asmari limestone which is capped by the thick beds of the Fars series, both of Miocene age. There are seven producing fields between Lali (on the Karun) and Gach Saran. A lesser field is exploited at Naft-e Shah, west of Kermanshah.

Makran.—This is a coastal plain and extended hill-land with a north–south strike east of Bandar Abbas which soon turns eastward into southwestern Pakistan. The region is extremely arid and vegetation is scanty. Erosion is heavy in the hills, caused by occasional rainstorms in winter, which also flood the coastal plain, the main area of cultivation. Fish has been a main resource on the coast since ancient times. Dried, it is exported or used as local food for both man and beast. Some of the interior valleys grow dates. (*See* also MAKRAN.)

Northern Border Ranges.—These comprise two distinct sections: the Elburz mountains (*q.v.*) and the border ranges of Khurasan. The Elburz mountains stretch in a great arc around the southern shores of the Caspian sea. Many peaks exceed 13,000 ft.; some bear glaciers (Takht-e Soleyman, Alam Kuh and Mt. Demavend). The slope to the Caspian is very steep with many torrential streams flowing in deep gorges. The southern and drier side has steep scarps overlooking immense gravel fans. Where deposits are fine enough to be irrigated they prove very fertile.

The Caspian plain, nowhere more than 25 mi. wide and generally less, dried out only in postglacial times. From a marshy lagoon coast it rises gently up to alluvial fans. The originally dense forest has largely been cleared or ruined into impenetrable bush, formed of christ's-thorn (*Zizyphus spina-christi*), pomegranate and other species. The warm and humid climate is favourable for a wide range of crops including rice, tobacco, cotton, citrus fruits and tea. It is one of the most densely populated regions of Iran.

The Elburz range declines in height to the east and finally, at 56° E., turns in a southeasterly direction. There the Khurasan ranges begin, the Kuh-e Aladagh and Kuh-e Binalud (11,200 ft.) and, north of the Atrak gorge, the Koppeh Dagh (10,000 ft.). The wide valley in between is drained to the west by the Atrak, to the east by the Kashaf Rud. The uplands, formerly clad in juniper forest, offer fair grazing grounds, while the valley is richly cultivated, especially near Meshed (Mashhad), which is often called one of the granaries of Iran. Besides being a city of pilgrimage, it stands at the Khurasan gap which witnessed more than one invasion from central Asia.

Central Plateau.—This is far from being the flat, featureless country so often pictured. It is crossed by a great number of ranges which, structurally, resemble the marginal folds. In their topographic appearance they betray the peculiar processes of arid land formation. Conventionally a long, quasicontinuous chain of various ranges which runs from west of Qom past Yazd and Kerman into the Sarhad-e Bala is called the Central Iranian range. There are other ranges of considerable length; *e.g.*, the Tabbas-Kerman and the Kuhistan-Sarhad ranges which merge into the Baluchistan folds. The valleys between the ridges have wide sloping sides which are largely gravel-covered pediments (*dasht*). The depressions are filled with silty colluvial masses, drenched in the wet period but, according to their salinity, covered by salt crusts when dry (*kavir*). The conception of great pluvial lakes, later dried up, is not supported by the facts. The Great Kavir, according to modern investigations, consists of a group of depressions separated by erosion surfaces which cap structures of the salt-bearing Upper Red formation. In the large depression of the southern Lut (*lut* = naked, bare of vegetation) wind erosion and deposition are the dominant processes. Within this area is a large massif of sand dunes (*rig*).

The largest oases are found in the northwest, on the inner slopes of the border ranges, and are fed by permanent streams; *e.g.*, Teheran, Kazvin, Qom, Mahallat, Isfahan, Nishapur (Neyshabur). Other smaller and dispersed oases depend for their water on subterranean galleries tapping underground sources of fresh water.

Eastern Borderland.—The eastern frontier of Iran cuts right through the grain of the country. In the north it follows the gorges of the lower Hari Rud, in the centre it crosses the great Seistan depression and in the south it traverses the Baluchistan ridges. The border country is a barren, almost uninhabited region, with an extremely low rainfall, extreme temperatures and violent winds. From the beginning of June the "wind of 120 days" blows with unceasing force from the north, excavating the ground and building up dunes. The lowest part of the Seistan basin is occupied by a fresh water lake, Hamun-e Saberi, which is fed by the Helmand and other Afghan rivers. Seistan was a centre of early Iranian civilization, but repeated destructive invasions and frontier quarrels have ruined it.

Khuzistan Plain.—In this plain the shallow anticlines of the Zagros foreland gradually die out and the extended gravel fans of the Karkheh, Dez, Karun and Zohreh rivers merge into the tidal flats at the head of the Persian gulf (*q.v.*). Rainfall diminishes in the same direction and steppe changes into semidesert, but irrigation water is plentiful and was used in early times. The Tigris swamps have always formed an effective barrier to the west, so this corner was the cradle of ancient Elam (*q.v.*) and played an important role within the Persian empires and early Islam. Decay set in later, but new development came with the oil industry and today Khuzistan is one of the most important provinces of Iran.

(H. Bo.)

III. THE PEOPLE

1. Racial Divisions.—When the name "Iran" was officially adopted for the country known for centuries as Persia, the intention of the shah was to stress the Indo-European origin of the inhabitants whose forebears had entered it from the central Asian steppes in the 2nd millennium B.C. But the people who are generally known as Persians are of mixed ancestry, and the country has important Turkish and Arab elements in addition to Balochis, Kurds (*qq.v.*), Lurs, and minority communities of Armenians, Assyrians (Nestorian Christians), Georgians, Dravidian Brahuis and Afghan Hazaras of Mongolian origin.

Kurdish nationalism (embracing the Kurds of Turkey, Iraq, Syria and Persia) received some encouragement from the British after World War I and, persisting as an intellectual movement, later flared up in local revolt in Persia as elsewhere; the separatist tendencies of the Turkic people of the Azerbaijan province received Soviet encouragement to rebel in 1945–46; and signs of hostility toward the Iranian government have been shown by the Arabs of Khuzistan. But, generally speaking, there is little racial animosity and considered as expressions of racial consciousness such outbreaks have usually been somewhat artificial. The great preponderance of Shi'ah Islam and the way of life prescribed by it form unifying factors transcending racial differences and the differences between tribesman, peasant and townsman and between six estates—*ulama* (the learned and religious leaders), nobles, landowners, merchants, citizens and peasants—into which Persian society was traditionally divided. The religious minorities —Christian, Jewish and Zoroastrian—are too small to create a problem, but discrimination against them is not unknown. The Kurdish tribes living on the northwestern borders from Reza'iyeh in the north to the plains of Kermanshah are nomadic and, until such movement was forbidden by Reza Shah Pahlavi, some crossed into Iraq on their annual migration after the melting of the snows in search of fresh grazing for their flocks. The organization demanded by these moves has kept alive the tribal system under the chiefs (agas), but mountain conditions have led to the breakup of the larger tribal units and there is little cohesion within the groups. Among the settled Kurds the tribal system remains, but the authority of the agas is less than among the nomads. The Lurs of the Pish Kuh and Posht Kuh ranges on the western frontier south of Kermanshah were almost independent of the government under their own valis (viceroys), until Reza Shah brought them under control and deported some sections to Khurasan. Their life resembles that of their northern Kurdish neighbours.

The Bakhtiari (*q.v.*), a large tribe of the southern Zagros, are akin to the Lurs; their main divisions are the Haft Lang, mainly nomadic, and the Chahar Lang, mainly sedentary. The name "Bakhtiari" is properly confined to the ruling families and their retainers. The leaders are among the most advanced tribal chiefs

of Iran; in 1906 they took a leading part in the revolution which led to the granting of a constitution. They show a keen business sense and for many years they were customarily educated in Europe, and their daughters received at least an elementary education. The women among the Kurds, Lurs and Bakhtiaris had in the past more freedom than did the women in the smaller towns and villages. They did not wear the veil and were not secluded from male company. In Kurdistan there is a tradition of matriarchy, and tribes have been successfully ruled by women. The Kashgai, a large tribe of Turkic origin, are neighbours of the Bakhtiari, with summer quarters extending over the highlands between Shiraz and Isfahan. In winter their flocks are found in the lowlands northwest and east of Shiraz. Reza Shah attempted to subjugate the Kashgai but they soon reasserted themselves after his abdication. A revolt of the tribe in 1946, when the leaders demanded autonomy on the pattern of that which the Azerbaijanis were expecting, was quelled, but the tribe remains an important political force.

The southern region of Khuzistan (or Arabistan) is more akin to the delta lands of southern Iraq both in physical geography and in population. Some Lurs visit the northern fringes for winter pasture but the majority of the population is Arabic speaking and tribal, whether sedentary or nomadic. The principal tribes are the Al Kathir and the Bani Lam, who have a large branch in eastern Iraq, on the Tigris north of 'Amarah. The sedentary and seminomadic tribesmen rear horned cattle and cultivate cereals or rice. Some also keep sheep or camels and own or work in date gardens.

In Khurasan bordering on the U.S.S.R. are the Turkmen tribes and some Kurdish and Balochi tribes. There are few nomads since conditions are favourable for agriculture, and the tribal structure, though persisting, is gradually being replaced by the village community. Throughout the country there are smaller tribal groups of varying racial origin, owing their present location to voluntary migration or to expulsion from an earlier home. They thus present a picture as confused as that of the detribalized elements of various racial origins among whom homogeneous blocks are even more rarely to be found. An exception is the Turkic community of Azerbaijan which has been settled for many centuries in more or less compact groups in the towns and villages of the province.

Whatever may have been the original population of Persia before the coming of the Aryan invaders, it was absorbed by them and by subsequent waves of conquering tribes whose blood has been mixed with that of the people of the plateau to a much greater extent than with that of the mountain tribes. Thus, among the Persian-speaking people there persists a widespread physical type on the border of the medium- and longheaded classifications for which the term "Iranian" has been reserved by some writers. Distinct from them are the shortheaded Kurds, Lurs, Bakhtiaris, Turki, Balochis and the people found in southern Fars and Makran who speak a language with Dravidian traces.

2. Language.—The languages of Iran are: Persian, Kurdish, Luri, Balochi and Arabic.

Persian (Farsi) is an Indo-European language based upon the Old and Middle Persian tongues which were introduced by invaders from the central Asian steppes east of the Caspian. After the conversion of Persia to Islam many Arabic words were introduced and a modified form of the Arabic script was adopted and is still used. In the written language some Arabic constructions also were adopted. There has been a tendency (as in Turkey) to expel Arabic words and forms, but devotion to the early literature, which contains them, hampers such efforts at persianization. Dialects are spoken in certain parts of the country.

Kurdish is a language distinct from Persian although belonging to the Indo-European group. The principal dialects are Gorani and that spoken by the Mukri Kurds of the northeastern district.

Luri, the language of Luristan, of the Bakhtiari and of some other tribes, has affinities with Old Persian.

Turkic.—The Azeri dialect of Turkish spoken in Azerbaijan is grammatically close to Anatolian Turkish but the pronunciation is broader. It has more Persian and fewer Arabic words than the Turkish of Anatolia. Turkic as spoken by the Turkmen of Khurasan is closer to eastern Turkish than to the Azeri dialect.

Balochi or *Baluchi* is an Aryan language mixed with modern Persian (*see* BALOCHI LANGUAGE).

Arabic is spoken by the Arab tribes of Khuzistan and along the coast of the gulf and of Makran, and by some sections of the Khamseh tribes of Fars. (*See* also IRANIAN LANGUAGES; PERSIAN LITERATURE.)

3. Religion.—The state religion is Shi'ah Islam (*see* SHI'ISM) of the Ithna 'Ashariya sect which recognizes 12 hereditary imams. There is also a Sunni minority. The Zoroastrians (*gabrs*) are relics of the followers of Zoroaster (*see* GABAR; ZOROASTRIANISM), whose doctrine was founded upon the ancient Mithraic faith; the majority of those who refused to accept Islam in the 7th century A.D. fled to India, where they formed the Parsee community. Jews have been in Persia since the Babylonian captivity. The Christian churches are represented by Nestorians (Assyrians), Armenians (Gregorians and Catholics) and Protestants and Catholics who are Europeans or else converted Assyrians or Armenians.

Muslims.—The Shi'ahs were, in the past, strongly influenced by the mujtahids (doctors of theological law), whose edicts affected political and other secular affairs until the 1906 revolution marked the beginning of a decline in their power. Reza Shah did much during his reign to break their authority, which was founded on the superstitious awe of the ignorant rather than on profound religious belief. Sunnis (2,000,000 approximately) are found in scattered groups in various parts of Iran. The compact communities are the Kurds, the Balochis and the Turkmen (Turkomans).

There are also some dissident sects: Sufis, the mystics whose teaching dates back to Abbasid times; the Isma'ilis, who originated in a schism after the death of the sixth imam (*c.* A.D. 797) and afterward created the society of the Assassins (*q.v.*) and who were the direct forebears of the modern Isma'ilis whose head is the Aga Khan; the Ali Ilahis, an extreme sect found among the Kurdish tribes; and the Baha'is, who, in spite of the repression of 1850, still exist in Iran and have played an influential part in the reform movements. The numbers of these sects are small and no reliable statistics are available.

Zoroastrians are a small community (15,000) living principally in and around Yazd and Kerman. They are both urban and country people, successful as traders and famed as gardeners.

Jews.—In spite of legal equality, the Jews are generally barred from important administrative positions, though some have deserted the traditional business of moneylending and trade and have become doctors. Small Jewish communities are to be found in most towns. Some have left Iran for Israel and the total number in Iran in 1960 was about 60,000.

Christians.—The Armenians number about 50,000 and are both rural and urban. Peasants are most numerous in Azerbaijan and the largest town communities are found in Tabriz, Teheran and Isfahan, where the suburb of Jolfa is almost exclusively Armenian. There are also some other very small groups of Christians. The Assyrians are Nestorians (*q.v.*) or Uniate Catholics (20,000) known as Chaldeans. Most of them live in the Urmia region of the northwest and are peasants, small traders, mechanics and motor drivers.

Catholic missionary work, begun early in the 17th century by the Carmelites, was suspended about 1780 but renewed in 1850 when the Lazarists opened a mission in Tabriz. Protestant activity dates from 1811. In 1829 a U.S. mission was established at Reza'iyeh and later taken over by the Presbyterians, who founded missions in Teheran, Tabriz, Hamadan and Rasht. The Church Missionary society began work at Isfahan in 1869. Until the time of Reza Shah, mission schools were tolerated, but the teaching of religion in all schools was forbidden in 1928 and the mission schools were absorbed into the state system. The hospital system was introduced to Persia by missionaries in the 1830s and hospitals, welfare centres and dispensaries continue to do most valuable work. Purely missionary activities meet with almost insuperable difficulties in Iran as in all Muslim countries.

4. Customs and Culture.—Iran is dominated by an agricultural society and the conduct, customs and moral outlook of all

classes, rural and urban, are greatly influenced by the way of life of the farmer, peasant and landlord. A notable feature of Iranian society is its fluidity, and though there are recognized classes transition from one to another is easy for there is no caste system. The individuality of the Iranian is a trait which perhaps partially explains the age-old reputation for tolerance of divergent customs, cultures and religious beliefs. The mullahs (priests) exercise such influence as they have in religious matters and in their guidance of public opinion.

The townsmen and villagers as a rule lead a fairly easy life and this has resulted in the development of a strong artistic taste, an appreciation of beauty and a keen sense of humour. With few exceptions the towns are commercial rather than industrial and have a large class of shopkeepers, craftsmen and traders, grouped by their common occupations and guilds. The peasants and tribesmen live in adobe houses or tents according to the climate of their district and their way of life.

Up to 1930 the position of women was on the whole better in the tribes than in the settled communities where they were entirely dominated by the men and their status suffered from polygamy and easy divorce. Much was done under Reza Shah to destroy old traditions by permitting women to discard the veil and seek employment. They enjoy equal legal standing with men, and in larger cities they engage in professional occupations. Women were given the right to vote early in 1963.

5. Population.—In Nov. 1956 the first nationwide census of population was conducted. From this census Iran was found to have a population of 18,954,704, of which 5,449,391 lived in towns of 5,000 inhabitants or more and the remaining 71% in 40,000 villages. A large proportion of the population is found in the area around Teheran. Other areas of dense population are the southern shores of the Caspian sea, the eastern half of Azerbaijan and the higher parts of Khurasan. Generally speaking, rainfall and elevation are two main geographical factors determining the distribution of population. In 1956 Teheran (*q.v.*) had more than 1,500,000 persons, but by 1959 it was estimated that the population had risen to 2,000,000. Other major centres with populations exceeding 100,000 are: Tabriz, Isfahan, Meshed, Abadan, Shiraz, Kermanshah, Ahvaz, Hamadan (*qq.v.*) and Rasht. Six cities have populations ranging from 50,000 to 100,000: Arak, Ardabil, Dezful, Kazvin (*qq.v.*), Yazd and Qom. There are 21 urban centres of 25,000 to 50,000 inhabitants and 50 smaller townships with 5,000 to 25,000 inhabitants. In 1961 the population of Iran was estimated to be 21,349,684. (M. H. GA.)

IV. ARCHAEOLOGY

A. Pre-Achaemenid Period

The physical geography of Iran did not encourage the early formation of political and economic unity. The central desert is uninhabitable and a barrier to communications, and life could develop only where there was water: in the mountain valleys, in the land between mountain and desert and in the outer plains of the Caspian and Khuzistan, ancient Susiana. Furthermore, Iran possesses adequate agricultural and mineral resources so that stimuli for the organization of an industrial and commercial economy were lacking. These conditions led in the prehistoric period to a great variety of local cultures and, except in Susiana which geographically is part of the Mesopotamian alluvial plain, delayed the growth of urban life; most of Iran remained illiterate until the 1st millennium B.C. The relative chronology of the early cultures depends for the most part on a limited number of stratified sites in the north and west and on correlations with the well-established sequence of Mesopotamia.

Paleolithic remains are known from cave excavations and surface finds, the earliest being a hand ax of Acheulian type. Industries found near Kermanshah closely resemble the Mousterian, Baradostian and Zarzian of Iraqi Kurdistan. The transition from food collecting to farming and settled life formed part of developments that began in the foothills of the mountain ranges between the Mediterranean and Turkistan, a zone in which prototypes of domesticated animals and cultivated plants existed in a wild state. A phase of incipient cultivation is attested at Tepe Asiab near Kermanshah, the earliest open-air settlement, which, though lacking architecture and pottery, produced blades with sickle sheen, ground stone ornaments and figurines (*c.* 10,000–7000 B.C.). A more advanced community, possessing both plain and painted pottery, occupied Tepe Sarab in the same area (*c.* 7000–6000 B.C.). Its assemblage is in part reminiscent of the upper levels of Jarmo in northeastern Iraq.

During the 6th and 5th millenniums village farming communities became well established (Sialk I–II, Chashmah Ali, Anau IA, Susiana tepes, sites in the Marv Dasht and Solduz plains). Hoes and sickle blades attest the practice of agriculture, and the goat at least was domesticated. Permanent dwellings were constructed, at first of mud but later of hand-shaped, sun-dried mud brick. Hammered copper tools make their first appearance (Sialk I, 3) and increase in number. Pottery shows greater refinement and variety in form and finish, painted wares having geometrical and representational designs. Whereas in the south and west the fabric was buff coloured, in the north and northwest it was predominantly red. On typological grounds these early settlements are comparable with those of the Hassuna and Tell Halaf periods in Mesopotamia, but evidence of connections between Iran and the west is slight, except in Susiana where the material culture had close affinities with that of Qal'at Hajj Mohammed in southern Iraq.

Further technical advances were made in the 4th millennium, notably the potter's wheel, molded brick, the casting of copper for tools and weapons and, at Susa, the invention of the semipictographic "proto-Elamite" script. Since this first appears on clay tablets in a level (Susa C) contemporary with the Protoliterate period of Sumer (late 4th millennium), the idea of writing may have been borrowed from the west. At this period Sumerian influence on the art of Susa is marked, particularly in glyptic. It was further strengthened in the 3rd millennium when Sumer developed close political and commercial relations with Elam (*q.v.*), the district of which Susa was a chief city. When in the second half of the millennium Elam fell under the domination of the Akkadian and 3rd Ur dynasties, Sumerian ritual practices, art and literature profoundly and permanently affected the native culture. The kings of Akkad and Ur built temples and made offerings to the gods of Susa, and the Akkadian language and script for a time largely supplanted proto-Elamite. At Kurangun and Naksh-e Rostam in Fars, rock carvings of a divine couple with worshipers also show Sumerian influence. Near Sarpol, in the ancient territory of the Lullubi, three rock reliefs of local rulers have Akkadian inscriptions which invoke Akkadian deities and in subject and treatment are close to the rock carving of Naramsin of Agade in the Darband-e Gawr pass (south of the Shehrizor) and to his victory stela. The best preserved is that of Annubanini, who is shown armed with bow and harpé trampling on a prostrate foe. The goddess Ishtar, represented according to Mesopotamian conventions, leads two bound and naked prisoners toward the king, and further prisoners appear in a lower register.

In northern Iran a culture characterized by burnished gray pottery with metallic shapes appeared early in the 3rd millennium and persisted into the 2nd (Hissar II–III, Turang Tepe, Shah Tepe, Asterabad treasure). In its later phase there was a great increase in wealth, probably due to trade along the route linking the Tigris and Oxus. Gold and silver were abundant and imports included Baltic amber and ivory, possibly from India.

Early in the 2nd millennium the replacement in the west of buff by red painted ware with new shapes, including the tripod (Giyan III), is connected by some authorities with the arrival of the Indo-Iranians, who imposed themselves as a ruling class in the native Kassite tribes. Subsequently the pottery, metalwork and iconography of western Iran show connections with the Amorite and Hurrian civilizations of north Mesopotamia (Giyan II–I, Hasanlu). In Elam the national revival of the 13th–12th century led to the most brilliant period in the history of its art. Its kings carried out extensive building work at Susa and other cities, notably at Dur-Untashi (modern Choga Zambil), southeast of Susa, which was founded by Untash-Huban in the 13th century and destroyed by the Assyrians about 640 B.C. An imposing ziggurat, numerous temples and a palace provide important evidence of cult

practices and funerary ritual and testify to the advanced technical skill of architects and craftsmen. The arts reached a high degree of perfection, particularly that of metalworking, as is shown by the magnificent bronze statue of Napirasu, the wife of Untash-Huban, from Susa. The importance of Iran as a centre of metalworking in the ancient near east is evident from the so-called Lorestan (Luristan) bronzes, obtained by the clandestine digging of tombs. They include weapons, horse trappings, jewelry and votive objects. The earliest are of the 3rd and early 2nd millenniums and show strong Sumerian influence. The majority, however, belong to the latter part of the 2nd millennium. The decorative themes are still largely inspired by Babylonia, but a distinctive style develops and the popularity of ornamental horse trappings expresses the interests of a population particularly concerned with horse breeding.

Between the 9th and 7th centuries western and northwestern Iran fell under the political domination of the powerful states of Assyria and Urartu and was also invaded by nomadic horse-riding tribes from the north, notably the Indo-Iranian Medes and Persians, first recorded in the 9th century, and the Scythians, who appear in the 7th century. These events find their reflection in Iranian art and architecture. At Hasanlu in the Solduz plain, the ancient district of Manna, a strong citadel and outer town were built in the 9th century, a period of Assyrian control. The basic culture was Iranian, with Hurrian elements, the characteristic pottery being the grayware of central Iran. A number of objects, however, are Assyrian in type, and the plan of two important buildings somewhat resembles that of contemporary north Syrian palaces (the *bit-hilani*).

At about the same time there is archaeological evidence of the arrival in central Iran of a new people, perhaps the Indo-Iranians (Sialk VI and cemetery B). They introduced new funerary customs and pottery, including a buffware elaborately painted with geometric and animal designs. A hoard found at Ziwiye, probably the ancient town of Izibie in Manna, contained objects of gold, ivory and bronze, some of which were local provincial work of Manna, while others were Assyrian, Urartian and Scythian. Judging from Assyrian sculptures, the fortified towns of Parsua and Media were similar to those of Urartu, where citadels were sited on natural hills and defended by walls of cyclopean masonry. Sargon II's relief of the temple of Musasir, west of Manna, shows a gabled building with a columned portico guarded by human and animal colossi. His detailed description of the rich loot taken from the temple proves that this district of Iran shared Urartian culture and religion. A number of rock tombs found in Media and Manna may have belonged to local rulers of the 9th to 6th century. The façade imitates a flat-roofed house with columned porch, the prototype of which was a wooden dwelling of a type still found in the area. A low door leads to one or more funerary chambers hewn in the rock.

In Elam the three centuries that followed the collapse of political power at the end of the 12th century are a dark period. A few objects from Susa and rock reliefs at Malamir show that there was a revival of art between the 9th and 7th centuries but there too Assyrian influence is evident.

B. Achaemenid Period

When the Persian and Median tribes first entered Iran their art was presumably that of a nomadic or seminomadic people—ornamental horse trappings, weapons, jewelry, leatherwork and the like—and they can have had little if any knowledge of architecture. In the course of their migration and eventual settlement, a process which in the case of the Persians lasted three centuries, they assimilated the civilization of western Iran, which, as has been shown, was strongly influenced by Assyria and Urartu. Nothing is known of the monuments of the short-lived Median empire, but this inheritance is manifest in those of the Achaemenids. With the foundation and expansion of the empire, Persian art became more cosmopolitan. As is graphically described in a foundation tablet from Susa, Darius I drew skilled craftsmen from all quarters of the empire for the task of building and equipping capital cities that would be worthy centres of imperial administration. Achaemenid art was thus not a new creation but the continuation of older traditions, Iranian, Mesopotamian, Urartian and, to a lesser degree, Egyptian and Greek. The Persian genius, however, integrated these diverse elements into a harmonious whole and in a remarkably short space of time evolved an imperial art, distinct from anything known earlier and in spirit essentially Persian. (*See* Persian Art.)

Architecture.—The period of Persian settlement in Parsumash under Achaemenes and Teispes may be represented by terraced structures of cyclopean masonry at Masjed Soleyman and Bard-e Nishundah. Their construction resembles that of the citadels at Pasargadae and Persepolis but the inferior workmanship suggests an earlier date. The principal sites of the imperial period are Pasargadae, built by Cyrus II between 559 and 550; Persepolis, the spring capital, work on which was begun by Darius I about 520 and continued by Xerxes and later kings; and Susa, the winter residence and administrative centre of the empire. Ecbatana, the summer residence, is unexcavated since it lies under modern Hamadan, but there is evidence of building by Darius I and Artaxerxes II.

At Pasargadae, Achaemenid architecture was still at an experimental stage. It reached its final form at Persepolis under Darius and Xerxes and thereafter remained static. In both cases, the choice of site was determined by the requirements of defense. As in Urartu, the citadel was placed on a natural spur of rock backed by a steep slope, the rock was leveled in terraces and was enclosed by a fortification wall of finely dressed limestone blocks, unmortared but joined by iron clamps. At Persepolis there is only one entrance approached by a double flight of steps. The fortifications continue up the hill at the back, and below the platform are an intervallum and wall enclosing a town area. On the platform, which varies in height from 8 to 18 m. (26–59 ft.) and is 135,000 sq.m. (161,459 sq.yd.) in area, stand public buildings (the Apadana, or audience hall, council hall, throne hall), the treasury and other administrative buildings, residential palaces and an extensive harem, all linked by courts and passages. More palaces lie in the town area. The Pasargadae platform is much smaller (6,000 sq.m.). It was originally designed as a palace enclosure but before its completion the capital moved to Persepolis and instead it was used for magazines and residential quarters. On the plain beneath are an audience hall, residential palace and gatehouse. They are widely spaced and originally stood in an irrigated garden surrounded by a wall. About one kilometre (.6 mi.) to the west is a sacred precinct with two stone fire altars and a terraced mound of uncertain function.

The basic unit of the Achaemenid palace is a hypostyle hall with a columned portico, the prototype of which was a wooden dwelling of the type depicted on the earlier rock tombs of Media and Manna. To this further porticoes and secondary rooms might be added according to the function of the building. A hypostyle hall without portico was used for the gatehouses and at Persepolis for subsidiary units of the treasury and harem. The plan of the treasury is unusual in that it has two interior courts. At Pasargadae the hypostyle halls vary in proportion from almost square to approximately 3:1, but at Persepolis they are usually square. The buildings were normally single-storied with a flat roof constructed of beams overlaid with mud. Interior lighting was obtained through doors and windows, but as these faced onto porticoes or corridors they admitted little illumination. Use of clerestory lighting is assumed, but evidence for it is found only in the audience hall at Pasargadae where the columns of the hall are higher than those of the porticoes. Unbaked mud brick was used for the superstructure and limestone for wall foundations, except in the treasury, harem and certain minor buildings at Persepolis. Limestone was also used for door and window frames, niches, antae and columns. In some buildings, however, column shafts were of timber encased in painted plaster. At Pasargadae the stone shaft was smooth and the torus either smooth or horizontally fluted in a manner which recalls archaic Ionic column bases. The stone impost block was composed of addorsed protomas of animals or mythical monsters.

At Persepolis the column became more elaborate. The shaft was

vertically fluted, an elaborate capital was interposed between shaft and impost block and, after Darius, the base was campaniform with plant ornamentation. In the time of Xerxes the number of columns was greatly increased, the throne hall and one of the treasury halls having a hundred. Another innovation at Persepolis was the cavetto cornice of doors derived from Egypt. A combination of black and white stone used effectively at Pasargadae for interior finish does not appear at Persepolis. Principal entrances were often flanked by bull colossi of Assyrian type, and sculptures in low relief adorned doors, some of the window frames and the parapets of stairs. The interior walls of the Persepolis Apadana were covered with glazed tiles having floral and animal designs, and the wooden door leaves had decorated gold plates.

At Susa the audience hall of Artaxerxes II is a hypostyle building similar to the Apadana at Persepolis, but the residential palace of Darius I is laid out on the Mesopotamian plan with three large interior courts off which open halls and living rooms. The monumental entrance and courts were decorated with molded and enameled brickwork. Four kilometres (2½ mi.) northwest of the palaces is a building of unusual type which may be a temple. It consists of a square columned chamber, surrounded by a passage and approached by a porch from which steps lead down to a courtyard enclosed by narrow chambers.

The Achaemenids built both rock and free-standing tombs. The earliest rock tomb is Da-u-Dukhtar, near Kurangun, which may belong to an early member of the dynasty. There are four at Naksh-e Rostam, near Persepolis, one of which is identified by an inscription as that of Darius I. The other three are uninscribed but are assumed to be the tombs of Xerxes I, Artaxerxes I and Darius II. Three more cut into the rock at the rear of the Persepolis platform presumably belonged to Artaxerxes II and III and Darius III. This type of tomb was directly derived from that found in Media and Manna, but there were new features. From the time of Darius, the exterior represented the façade of a royal palace with the characteristic columns and cavetto cornice; a narrow passage with niches for coffins replaced the funerary chamber; and the rock was cut back above the tomb façade to accommodate an elaborate relief. This depicts the king standing, bow in hand, before a fire altar with Ahura Mazda in the winged disk and the moon floating above. The king's dais and the altar rest on a throne, the crosspieces of which are supported by figures representing the subject peoples of the empire, a device known in Assyria. In contrast the tomb of Cyrus II at Pasargadae is free-standing. It is a reproduction in stone of a single-chambered wooden house with gabled roof and stands on a high stepped platform. There is a similar tomb, Gur-i-Dokhtar, south of Kazerun.

Two identical limestone towers, one at Naksh-e Rostam and the other at Pasargadae, are identified by some authorities as fire temples, by others as tombs. Each stands on a stepped platform and is approached by stairs, the total height being about 12 m. The interior contains a single chamber, without windows, which was hermetically sealed when the door was closed. The exterior reproduces a three-storied building with flat roof, dentil cornice, corner posts and simulated windows. This type of house is known from Urartian bronzes and depicted on 7th-century Assyrian sculptures of north Iranian towns.

Sculpture.—Achaemenid sculpture is represented by palace reliefs, the carvings on rock tombs, the monument of Darius I at Bisitun (*q.v.*) and a few free-standing statues. Relief sculpture, in which the Persian artist excelled, formed the principal decoration of the royal palaces at Pasargadae and Persepolis. It was an integral part of the architecture, which determined its position and dominated the principles of its composition. A combination of high relief and sculpture in the round was used for the bulls and winged bulls with human heads of the gatehouses and palace entrances, and for the animal protomas of columns. Low relief was applied to the inner surfaces of door jambs, window frames and the parapets of stairs. All the themes are associated with royalty and in many cases depict court ceremonies which took place at the spot where they were displayed. In the palace interiors at Persepolis the king is shown enthroned and accompanied by an attendant or the crown prince, giving audience, and entering or leaving the main hall. In the residential palaces his personal servants, carrying paraphernalia for the royal ablutions or provisions for the table, appear in the doors of small rooms and in the windows, and sentries stand on duty at the guard chambers. Another group of door-jamb sculptures depicts a king or hero in combat with a lion, bull or mythical monster. On the platform steps are guards and the people who passed up the steps on business: Persian and Median dignitaries ascending to the council chamber, servants carrying supplies to Darius' residence. The most ambitious composition of this type, nearly 300 ft. in length, is the representation of the Nauruz, or New Year festival, on the two stairs leading to the Apadana platform. Files of Median and Persian officials, royal guards and tribute bearers from 23 nations converge before the palace, and plant motifs and symbolic groups of lion and bull combat and the winged sun disk flanked by sphinxes are used decoratively as space fillers. The design is identical on both stairways, but the processions move in opposite directions with all the changes resulting from the different angle of vision. In scale and conception these Apadana reliefs are unparalleled in ancient western Asiatic art.

At Pasargadae low relief is found only on the door jambs and most of the sculptures are fragmentary. The king leaving the palace occurs in the private residence, but the other subjects are different from those of Persepolis. A four-winged figure with Elamite robe and Egyptian atef crown stands in the gatehouse and mythological beings such as a bull man and fish man, only the feet of which remain, in the audience hall.

In the representation of these themes certain set conventions were rigidly applied—for example, the division of a subject into horizontal registers, the rendering of figures in profile and their projection on a single plane, hierarchic scaling and isocephaly. Portraiture does not exist and little attempt is made to depict ethnic differences other than by costume. Details such as embroidery or metalwork are, however, carved with exquisite precision. The monotony of a repetitive and restricted repertory is further increased by the rendering of themes in pairs, usually as mirror images. Nevertheless the original effect of the sculptures was brilliant, for they were at least partially painted in vivid colours and in some cases the royal beard and jewelry were inlaid with metal and precious stones.

Achaemenid sculpture was ultimately derived from that of Assyria, perhaps through Media, although evidence is lacking. Its themes, artistic conventions and technique are all found in Assyrian art. The earlier tradition was, however, considerably modified, an important factor being the need to adapt it to a different style of architecture. In the mud-brick palaces of Assyria sculpture was applied to orthostats lining doors and the walls of interior courts, chambers and corridors. In Persia orthostat reliefs occur only in an interior court of the brick-built treasury. With this single exception, Achaemenid sculpture was confined to stone architectural members of restricted area, doors, windows and stairs. On such surfaces the great Assyrian pictorial narratives of battle and hunting were inappropriate and are totally absent. While the dominant influence on the development of Persian sculpture was incontestably Assyrian, the rendering of drapery and perhaps also the greater plasticity and definition of modeling as compared with Assyrian work may be attributed to the Ionian craftsmen employed by the Achaemenid kings in the construction of their cities.

The theme of the victory relief of Darius I carved on the rock at Bisitun continued an ancient tradition. The attitude of the king standing bow in hand with one foot on the prostrate Gaumata, the file of prisoners before him and the victory-giving deity, in this case Ahura Mazda, can be paralleled as early as the 24th century on the monuments of Naramsin of Agade and the rock carvings of the Lullubi kings (*see* above).

Minor Arts.—With the growth of a wealthy and luxury-loving court, the Iranian metalsmith found full scope for his traditional skill and produced jewelry, dress ornaments, weapons, tableware and decorative elements for furniture of unsurpassed quality and design. Gold and silver were used extensively and semiprecious stones, paste and glass were combined in multicoloured inlay.

Stylized animal motifs, and especially fantastic creatures of Mesopotamian inspiration, predominated. Rich jewelry was worn by both sexes, the most characteristic types being the torque and armlet, both of which are open hoops, often with terminals in the form of an animal's head or body. Gold bracteates and roundels were sewn onto garments, a practice known in western Asia from the 2nd millennium. The description given by Herodotus of the Persians in Xerxes' army can be no exaggeration: "They glittered all over with gold, vast quantities of which they wore about their persons." The tables of the rich were graced by superb rhyta, amphorae and drinking bowls, and weapons were elaborately ornamented with intricate designs. Achaemenid metalwork has been found in Persia, Mesopotamia, Asia Minor, Egypt, Cyprus and Russia. The majority of the pieces, however, have been obtained not from excavations but from dealers, so that their provenance is often unknown. One important group of goldwork, distributed among museums and private collections, is said to have come from Hamadan and to have been found in association with inscribed gold plaques of Arsames and Artaxerxes II. It presumably formed part of a royal treasure.

In glyptic art many of the subjects and the modeled style of cutting were inherited from Assyria and Babylonia, but Greek influence is apparent in the more spacious treatment of the background and in certain elements of the designs. It was particularly strong on the seals of Asia Minor, which were probably cut by Greek engravers. Subjects include scenes of battle, hunting and domestic life, combat between man and beast, and animals, both actual and imagined. Private persons normally used stamp seals, either conical or scaraboidal in shape, but the cylinder was retained for official purposes. (J. M. M.-R.)

V. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—Up to 1906 the shah was an absolute monarch in the ancient tradition. He delegated wide powers to a grand vizier but was himself absolute in legislative, executive and judicial functions. The mullahs exercised considerable temporal as well as spiritual power and played an important part in the events leading to the setting up of a national consultative assembly (*majlis*) by Muzaffar-ad-Din Shah in 1906 and the first grant of a formal constitution.

The fundamental laws of the constitution dealt point by point with the constitution, duties and functioning of the *majlis* and the conditions regulating the formation of the senate. A supplementary fundamental law was promulgated on Oct. 7, 1907, in which Islam, according to the Shi'ite Ja'fari doctrine, was prescribed as the official religion of Iran, which the shah must profess and foster. The *mujtahids* (doctors of theological law) are its guardians and a committee of no fewer than five "*mujtahids* or other devout theologians," properly elected, may veto any law which infringes Islamic ordinance. This power seems to have remained largely theoretical. The right of equality before the law, the guarantee of life, liberty, home and honour; the right to be tried in an appropriate tribunal; the liability only to penalties laid down by the laws; the right of property; the right to freedom of teaching; a free press; freedom of assembly and the secrecy of the post—all were set out at length. The powers of the state derived from the nation are defined as legislative, executive and judicial in such a way as to form a representative constitutional monarchy. The shah derives his power in trust from the people. These powers, like those of the *majlis*, are defined. The ministers are responsible to the *majlis* and the senate for all acts carried out in the name of the shah, and the shah's person is exempted from all responsibility. The appointment and dismissal of ministers is effected by royal decree and it has become the practice, when a new prime minister is required, for the *majlis* to meet and agree on a name for submission to the shah; the shah appoints the person named and the latter selects his ministers for the shah's approval. If the *majlis* or the senate, by an absolute majority, declares itself dissatisfied with the cabinet or with one particular minister, that cabinet or minister must resign. The number of deputies in the *majlis* was at first 162 but had been raised to 200 by 1957 and the term of office extended from two to four years.

In April 1949 a constituent assembly was formed to examine the draft of two new articles of the constitution, one of which gave the shah the right to dissolve either or both chambers while the other laid down the procedure for future amendments of the constitution of 1906. Under that constitution there was to have been a senate with 60 members, 30 elected and 30 nominated by the shah. No steps were taken, however, to create the senate until 1949, when the *majlis* passed a bill laying down the procedure for its election. This bill conformed generally to the articles of the fundamental law constituting the senate but stipulated that the internal regulations of the senate were to be approved by the senate itself (not by the *majlis*) and prescribed a system of two-stage election for the members. The first senate assembled in 1950. Laws may be initiated by the shah, by the cabinet, by the senate or by the *majlis*. Bills initiated by the cabinet are debated in the *majlis;* those proposed by the *majlis* are sent to the senate. The shah's signature is necessary before any bills can become law. Only the *majlis* has the right to enact and approve laws connected with revenue and expenditure. The supplementary law of 1907 provided for the establishment of provincial and departmental councils (*anjunmans*) but no steps had been taken to establish them by the early 1960s. The cabinet comprises a prime minister with, usually, 13 to 15 ministers.

After 50 years of trial of the constitutional parliamentary system no truly independent parliament and cabinet had yet been established. All economic affairs are centralized in the high economic council which is presided over by the prime minister.

From 1925 to 1941 Reza Shah had ruled with absolute powers, ignoring the constitutional checks upon them, and all control of affairs passed out of the hands of the *majlis*. His successor respected the constitution but the amendments of 1957 strengthened his prerogatives.

2. Provincial Administration.—Until 1938 Iran was divided into 26 provinces. In that year a reorganization took place and ten large provinces (*ostans*) were created. These were subdivided into districts (*shahrestans*). Further adjustments took place in 1946 and in 1947 (when Teheran, the capital, became an *ostan*). The administrative divisions as of 1961 are shown in the table.

TABLE I.—*Ostans and General Governorships*

Ostan and capital	Area (sq.mi.)	Pop. (1961 est.)
Baluchistan-Seistan (Zahedan)	69,807	482,509
Central (Teheran)	36,139	3,703,194
East Azerbaijan (Tabriz)	26,656	2,312,499
Fars (Shiraz)	50,656	1,230,336
Gilan (Rasht)	15,753	1,568,256
Isfahan (Isfahan)	9,409	1,550,336
Kerman (Kerman)	71,197	655,974
Kermanshah (Kermansbah)	17,529	768,000
Khurasan (Meshed)	120,710	2,261,197
Khuzistan (Ahvaz)	24,167	1,491,661
Kurdistan (Sanandaj)	10,873	625,766
Mazanderan (Sari)	20,386	1,376,461
West Azerbaijan (Reza'iyeh)	17,452	878,797
General governorships		
Bakhtiari-Chahar Mahall (Shakrkord)	10,502	383,590
Hamadan (Hamadan)	7,413	783,258
Luristan (Khorramabad)	11,737	585,421
Oman Sea (Bandar Abbas)	23,228	266,547
Persian Gulf (Bushire)	9,494	223,744
Semnan (Semnan)	26,255	202,138
Total	636,363	21,349,684

Each *ostan* is administered by an *ostandar* (governor general), appointed by and directly responsible to the minister of the interior. He is assisted by a staff from other departments, health, education, etc., appointed by their ministers. The *shahrestan* is under a *farmandar* (governor); further subdivisions are the *bakhsh*, consisting of *dehistans* (rural areas and groups of villages). Cities in the larger administrative divisions have their own municipality or town council under a mayor appointed by the minister of the interior. The Teheran council has 12 members; the town councils in first-class *shahrestans* have 9 and the others 6. Members, who receive no salary, are elected for two years. Under the mayor they determine the kind and amount of the municipal taxes, study and approve the municipal budget (which must have the final approval of the minister of the interior) and supervise the financial affairs of the town. The administrative system, which is based on

the prefectural system of France, is seen to be highly centralized. (*See* also separate articles on the *ostans.*)

3. Political Parties.—Political party organizations date only from the earlier years of the 20th century. Secret political parties were first created by progressive elements of the intelligentsia with the object of fighting foreign influence as well as the despotic monarchy. They established contact with corresponding and sympathetic political groups abroad and played a significant part in bringing about the constitutional revolution. Since that time, political activities have occasionally been suppressed or restricted as under Reza Shah (1926–41) and after the fall of Mohammed Mossadegh (*q.v.*) in 1953. There were three distinct phases of activity, during which no less than 30 different parties and groups developed.

The Fall of Mohammed Ali Shah (1908) to the Accession of Reza Shah (1926).—Absolute freedom of political activity prevailed during this period and parties were formed such as the "Democrat," with liberal outlook, which was effective in the overthrow of Mohammed Ali Shah's dictatorship. The Etedaliyun party, composed of Qajar princes, big landlords and religious leaders, was opposed to the Democrats. The Adalat was the first Communist party organized in Iran after World War I (not to be confused with a party of similar name organized between 1942 and 1945).

From the Occupation of Iran by the Allies (1941) to the Fall of Mossadegh.—During this period more than 20 political parties and groups were formed. The main parties were the Tudeh party of Iran, the Democrat-e-Azarbaijan, the Democrat-e-Kordestan (all of leftish inspiration), the Eradeh-Melli and Adelat (anti-Communist) and the Iran party. The Tudeh party was the most vigorous political organization, enjoying the full support of the Soviet government and reached its zenith in 1945 with three ministers in the cabinet. It was legally banned in 1949 after an abortive attempt was made on the life of the shah, and then went underground and succeeded in extending its activities into the defense forces until 1956 when its secret network was discovered and military leaders executed or imprisoned. Since then the Tudeh party has pursued its activities outside Iran and behind the iron curtain. The Iran party was established in 1944 by a group of the intelligentsia, mostly trained abroad, with the main object of fighting foreign influence. In 1948–49 it pursued a purely nationalistic and anti-Communist policy. On Mossadegh's fall it lost its importance, but its leaders were repeatedly involved in political unrest from 1957–61. The Goruh-e-Iran-e-Now (formed in 1954) was composed of a small number of well-educated young men, some of whom filled important government positions after 1957.

The Period 1957–61.—Early in 1957 the ban on political party activities was removed and two new parties were formed. The Mardom (People's party) won 40 seats in the 19th *majlis*, held its first congress in Oct. 1959 and in the elections of the summer of 1960 gained 50 seats, though all the deputies subsequently resigned. The Melliyun (National party) was organized in 1958 by Manuchehr Eghbal, who was then prime minister; in the elections of 1960 this party won 120 seats and had a majority in the *majlis*, but when these elections were nullified and its leader resigned his post, the Melliyun too faced a crisis.

The 20th *majlis* which followed the 1961 elections was dissolved by the shah after Ali Amini formed his government in May 1961, and party political activity in the country subsequently declined to a minimum.

4. Taxation.—Until 1899 there was a system of tax farming which led to many irregularities and abuses; this was abolished but not until the 1906 revolution was any real improvement introduced. A ministry of finance was then created and between then and 1927 Belgian and American missions (the latter under Morgan Shuster and A. C. Millspaugh) did create an orderly tax system. Many new laws and regulations were mostly related to indirect taxes. In 1956 a comprehensive tax law superseded the existing tax laws. This law, which was revised in 1958, dealt with all classes of taxes such as those on wages and salaries (7% to 50%), real estate, cultivated lands, banks and companies, contract transactions, professional occupations, etc.

5. Working Conditions and Housing.—Wages are low in comparison to the cost of living. This is especially true of the farmers and peasants who earn far less than urban factory workers or labourers. Available statistics reveal that between 1936 and 1955 the cost of living in Iran increased twelvefold whereas the increase in the daily wage level was barely fivefold. In certain industries wages vary from place to place; *e.g.*, labourers engaged in construction work in Teheran or oil workers of Abadan are paid as much as 250 rials, considerably higher than the daily average, which in the early 1960s was 45 rials for unskilled workers (£1 = 214.4 rials approximately; $1 = 76.5 rials).

The Labour law of 1959 calls for a 48-hour week, paid vacations, employment contracts and collective agreements, health and safety regulations and registration of labour unions and employers' organizations. The employment of foreigners is controlled by regulations enacted in 1960. The Worker's Social Insurance law (1960) provides for a system of social security benefits including coverage for sickness, retirement, maternity, family allowances, etc. However, all these labour and social provisions are confined mainly to small groups of industrial workers and mineworkers and are not widely enforced.

In Oct. 1961 the shah created the Pahlavi Dynasty trust to which he donated an estimated $140,000,000 worth of his personal properties. The trust was an expansion of the Pahlavi foundation established in 1958 to encourage economic and social development and the improvement of living conditions.

Housing.—Up to 1941 housing presented no special problems but the great influx into the cities, particularly Teheran, which began after the Allied occupation, led to higher rents which, in turn, forced the government to distribute cheap land among its employees for building private houses. The experiment went on successfully in Yusofabad to the north of Teheran. Ministries and government agencies as well as some banks and larger business concerns executed housing projects for the benefit of their employees. Organizations such as the Bank Sakhtemani (construction bank), the Bank Rahni (mortgage bank), Sherkat Sahami Bimeh Iran (Iran Insurance company) and the State Housing organization (created in March 1958) played a large part in planning and financing such projects, especially on the periphery of larger cities. By the early 1960s there was a noticeable slowdown in building activities, but the organization was responsible for the construction of 10,000 small houses in the earthquake and flood-stricken areas.

6. Public Health and Welfare.—In 1904, in accordance with a provision of the International Sanitary convention held in Paris during the previous year, a sanitary council was created. In 1925 the president of the council became the director of public health services, and in 1945 the ministry of health was established. Until 1911, when it became obligatory by law for all students of medicine to take a diploma of the Government Medical school, certificates to practise had been given to apprentices of Iranian doctors and to assistants trained in foreign hospitals. This reform made possible a gradual expansion of the medical services.

In the early 1960s the ministry of health had on its payroll more than 4,500 trained medical officers (including physicians, assistant physicians, surgeons, midwives and dentists) working at hospitals, dispensaries and medical posts distributed over the country. In addition there were many private hospitals sponsored by foreign missions, commercial institutes and charitable foundations. Following the seven-year plan of 1947 the country was divided into a number of health districts in which systematic campaigns against diseases such as malaria and trachoma were successfully conducted. Private social security and welfare agencies include the Workers' Insurance, Social Insurance and Imperial Social Services organizations and the Red Lion and Sun society, some of which provide dispensaries in remote villages.

7. Justice.—Before the constitution of 1906 there existed in Persia two systems of law: the *Shari'a* or Islamic religious law based on the Koran and administered by the clergy, and the common or customary law known as *urf*, which governed transactions not specifically covered by the *Shari'a*, although, theoretically, the Islamic law applies to every act of man. (*See* ISLAMIC LAW.) In

addition to these were royal edicts. The Islamic law gradually became restricted to questions of personal status (marriage, inheritance, etc.), faith and morals. The *urf* represented local custom in matters such as water and grazing rights, landlord-tenant relations, etc. The shah's edicts covered public administration, public security and taxation. The fundamental law of 1907 laid down the general principles of criminal and civil procedure. In 1912 a new law set up a judicial administration modeled upon European standards and in 1914 a system of commercial courts was established. Attempts to enforce these measures and to introduce reformed legal codes were successfully blocked by the action of the mullahs and it was not until Reza Shah came to power that modern systems were enforced. The civil code, based upon the *Shari'a* with adaptations from the French code, was adopted in 1928 and absorbed most of the functions of the Islamic law. The penal code, abolishing the principle of the *lex talionis* (law of retaliation), was introduced in 1926 and is also based upon French law, as are the commercial code and the civil and criminal codes of procedure. The most important change was the authorization by the *majlis* in 1928 of the articles of the civil code which provided a uniform basis for the application of the modified *Shari'a* law and thus eliminated the individual interpretations of the *mujtahids*. In 1931 the privileges of the teachers of Islam were further curtailed by a law requiring that all marriage contracts and acts of divorce be registered with a civic official. The law is administered by minor courts which sit in villages and small towns with a single magistrate and have jurisdiction in civil cases involving small sums and petty offenses. Appeal is to the district courts which correspond to the French courts of first instance and deal also with major misdemeanors and with the more important civil cases. The provincial high courts, to which lie appeals from the district courts, deal with offenses classed as crimes and with disputes between examining magistrates and public prosecutors of the district courts. The supreme court of cassation or appeal is in eight sections and hears appeals from the provincial courts or from special tribunals.

Police.—The police, some of whom carry firearms, are subject to the minister of the interior and are nominally under the local civil governors, though there is a chief of police in larger towns.

Jurisdiction Over Foreigners.—A system similar to the regime of capitulations in Turkey was voluntarily conceded by a firman of Shah Abbas to Sir Anthony Sherley in 1600 to induce British merchants to enter Persia to trade. But although these privileges were extended to the nationals of other countries they were not formally recognized until 1828, when, under the terms of the treaty of Turkmanchai, Russia obtained important commercial and diplomatic privileges. Russian consuls, with extraterritorial rights, could be appointed at will. Similar rights and privileges were later granted to other powers by virtue of most-favoured-nation clauses in other treaties. These privileges were renounced by the Russians in their treaty of 1921. In 1927 after the reformation of the judicial system (which was necessary to make it acceptable to foreigners) Reza Shah announced the formal abrogation of the capitulatory regime, to take effect within 12 months. The French government accepted at once. The British government objected on the ground that the rights which their nationals enjoyed were based on firmans issued by shahs of Persia before the signature of the treaty of Turkmanchai and on general international law. Eventually abolition was accepted as part of a settlement of various matters under dispute, and with the introduction of certain safeguards which applied to British subjects and to most other foreigners. These provisions may be summarized as the application of international law to all foreigners; the use of only written evidence in court cases; nonjurisdiction of religious courts over foreigners; limitations concerning imprisonment, arrest and search; access by an arrested foreigner to his consul; facilities for release on bail; imprisonment in hygienic conditions; trials to be normally public; in personal matters facilities for recourse to the national's courts and nonliability to civil arrest in normal cases.

8. Education.—Until the first reforms were introduced by Nasir ad-Din (*q.v.*) in the middle of the 19th century, education, in the narrower sense, had been centred in the religious schools, the *maktabs* in the villages and towns and the *madressehs*, or religious colleges, which gave higher education in theological subjects, law and medicine. But Persia enjoyed the advantage of widespread and popular interest in its literary heritage so that, unlike other Muslim countries of the period, education, in spite of the illiteracy of the majority of the population, was founded upon the Koran and also upon the Persian classics, which are still widely known by recitation. In 1852 Nasir ad-Din founded the Dar ul-Funun (College of Science) in Teheran and three years later established a ministry of science and arts, aiming to create a teaching body in the first instance and then to modernize and extend primary education. A translation bureau was formed in 1862 to translate European works into Persian, and a royal library in 1873, the year of the shah's first visit to Europe. He then decided to send a few young Persians of good family to France for military training at St. Cyr, for engineering at the École Polytechnique, and to study law and medicine and modern art. But the development of the modern educational system more properly dates from 1897 when a "society for the establishment of national schools" (afterward known as the Anjuman-i-Ma'aruf, or Education council) was founded. Its efforts resulted in the opening of numerous elementary and secondary schools, which with some foreign schools (notably the American Mission college which had been founded in Teheran in 1872, the Anglican Stuart Memorial college founded in Isfahan in 1904 and French Catholic schools) formed the basis upon which subsequent progress was made. The constitution of 1906 emphasized the importance of modern education and the freedom of all to study sciences, arts and crafts and to publish books, provided that religious laws were not transgressed. The establishment of schools at government expense and the regulation of compulsory education were recognized as a national responsibility. In 1911 a ministry of education was established. Its work was greatly extended between 1911 and 1921 but the chief impetus was given after the accession of Reza Shah in 1925. In the 1960s thousands of Iranian students were studying in American and European educational institutions.

The educational system is centralized under the ministry of education, which has directorates general dealing with education proper, vocational education, physical training, administration, higher education, inspection, fine arts, publications, archaeology, the national library and religious foundations (waqfs). Other ministries, *e.g.*, labour, industries and mines, roads and communication, and posts, telegraphs and telephones, have their own training centres, but the ministry of education has a general supervisory power over all such centres and over all private educational institutions. The school period up to university level is 12 years, equally divided between elementary and secondary education, with specialization for three years prior to university entrance.

There are six universities (Teheran, Tabriz, Meshed, Shiraz, Isfahan and Ahvaz), with about 35 faculties and about 17,000 students. The University of Teheran, founded in 1934, has 13 faculties with about 12,000 students, and includes an institute of nuclear science established in 1959 under the aegis of the Central Treaty Organization. The teacher training college, formerly part of the university, was accorded independence, but replaced by Teachers Training institute in 1963. The nongovernmental National university was also in the process of formation and the Institute of Technology in Teheran reached university level in various fields of technology by the early 1960s.

In 1963 the Shah created the "knowledge corps," a semimilitary organization attached to the ministry of education. All conscripts holding high school certificates are enrolled in this corps and required to spend their compulsory military period in educating illiterate villagers.

9. Defense.—During the reign of Nadir Shah (1736–47) British, French, Italian and Austrian military missions in turn took a hand in the organization of the Persian army, but the Cossack brigade, founded in 1882, armed and trained on the Russian model and commanded by Russian officers, was the only efficient unit. In 1921 the Cossack brigade had a strength of about 14,000; the household troops about 20,000; the South Persia rifles, British-trained and equipped during World War I, about 6,000; and the

Swedish-trained gendarmery (*amnieh*) about 12,000. When Reza Khan became minister of war he immediately began to organize the army purely on Persian national lines, and his ability to secure the downfall of the Qajar dynasty and to seize and retain power was a result of the new spirit with which he imbued it. By 1939 the strength of the army had increased to 105,000 and it had considerable successes against the tribes. But it had to yield before the British and Soviet forces in 1941. A conscription law of 1925 (somewhat modified in 1938) prescribes two years' military service for men over 21.

The three armed services are all controlled by the minister of war. The strength of the army in the early 1960s was about 200,000 and consisted of six corps. The air force had 8,000 officers and men and was equipped with U.S. jet and propeller aircraft. The navy, with 6,000 men, had a number of frigates, mine sweepers, gunboats and other smaller vessels in the Persian gulf. After 1950, in addition to the military academy and the command and general staff school, basic and advanced branch and service schools were established. United States military missions are attached to the army and gendarmery and the staffs are organized on the U.S. pattern. The chief of the supreme commander's staff is directly responsible to the shah who is the commander in chief of the armed forces according to the constitution. Iran is committed to collective defense through membership of the Baghdad Central Treaty Organization (CENTO), formerly Baghdad pact (*q.v.*).

VI. ECONOMY

A. Production

In 1946 the government initiated a seven-year plan for the development of the country's economy, which is based mainly on oil production and refining and on agriculture, and created a board which presented an outline plan, approved by the *majlis* in Feb. 1949. A detailed project prepared by a U.S. firm in 1947 was not adopted, and further recommendations submitted by another U.S. firm were presented to the government in Aug. 1949. Of an estimated total expenditure of $656,000,000, agriculture was to receive 25%, transport 23.7%, industries and mines 14.3%, petroleum development 4.8%, communications 3.6% and social welfare 28.6%. The whole of the revenue from the petroleum industry was earmarked for the plan, which went into effect in 1949. Progress was hampered by the cessation of oil revenues after the first two years and by the inability of the Bank Melli Iran to grant adequate loans in face of the other needs of the government.

With the resumption of oil output in 1954 the prospects were greatly improved and a second seven-year plan estimated to cost $930,000,000 was approved in March 1956. By the early 1960s the plan organization had considerable achievements to its credit in its agricultural projects but it was not so successful in the field of industry. Production of construction materials, textiles and sugar was increased significantly. By January 1962 Iran's third economic plan for the period Sept. 1962–Sept. 1967 had been prepared. Its aims were to further economic growth and the raising of the national income by an average of at least 6% per year. The total development outlay was estimated to be 348,000,000,000 rials. Project allocations were: agriculture 20%, industry 28%, transport and communications 26% and social projects 26%.

1. Agriculture.—Although Iran is primarily an agricultural country, the percentage of the whole area under cultivation is extremely small. In addition to the vast deserts and the land lying fallow each year, very large cultivable but unused areas await development. Water is wasted, methods are out of date, landholdings are often uneconomical in size, and the system of land tenure gives little incentive to the cultivator.

The bulk of the land is held under three main types of ownership: (1) *khalisa* lands, which are public domains, sometimes leased in large blocks to wealthy persons who then often sublet; (2) *milkiat*, land held in full private ownership in accordance with Islamic law; (3) waqf, land held in trust either for groups of persons or for religious or educational purposes.

Tradition and these types of ownership favour absentee landlordism. It was estimated that the class holding 250 ac. (100 ha.) or more constituted only 0.2% of the total rural families and landowners but held 33.8% of the total annually cultivated land. Crop sharing varies in different parts of the country but, in general, is based on the principle that there are five factors in production—land, water, seed, oxen and labour, the last including implements. Whoever provides one of these elements receives one-fifth of the crop. This system applies both to the crop-sharing peasants and to small landowners or communal owners working their own land, but not to leasehold or hired labour. It is modified by local custom and differs between summer and winter and between irrigated and rain-fed crops. In 1946 and 1952 decrees were issued by the government designed to modify this system so as to improve the peasants' lot, but the difficulty of applying them hampered their effectiveness. In 1951 the shah issued an edict for the sale of crown lands on long-term installments to farmers occupying them. The area affected exceeded 800,000 ac. of cultivated or potentially cultivable land. By the early 1960s more than 25% of this land had been distributed under this program. In 1954 the government presented a bill to the *majlis* for the distribution of more than 10,000 ac. of state lands. In Jan. 1962, in the absence of parliament, the shah gave his assent to the amended land reform law under which no landlord is allowed to own more than one village; it was first applied in Azerbaijan.

Water Supply.—It is estimated that, of the total cultivated area, about three-fifths is dry-farmed, two-fifths irrigated. Methods of irrigation are as follows: (1) *Qanats*, water channels, sometimes 13,000 ft. long, tap the water table underground at a level higher than that to be irrigated. The slope of the *qanat* is less than that of the surrounding land and the water is delivered by gravity. The *qanat* is the traditional Persian system of irrigation, though it is used also to a limited extent in Iraq and northern Syria. (2) River irrigation using brushwood dams is common and the dams are renewed annually. Under the seven-year plan there were numerous projects for irrigation from surface sources. (3) Wells with water wheels are used chiefly in the south; these consist of skin buckets worked by oxen. (4) Plans for drilling 2,300–3,000 tube wells to irrigate about 600,000–700,000 ac. were part of the seven-year plan. A dam on the Karaj river near Teheran (inaugurated in Oct. 1961) stores 200,000,000 cu.m. In addition to irrigation, it provides part of the city's water supply and electric power. Another dam on the Dez, in the southwest of Iran, was completed in 1963.

Farming Methods.—Most of the agricultural work such as seeding, planting, reaping and threshing is done by hand, and the implements used in farming are primitive and few. Iron-tipped plows, wooden drags, light mattocks, long-handled wooden spades and sickles are among the chief agricultural implements. However, mechanical methods are gradually taking the place of the old and primitive ones. By the early 1960s imported tractors and other agricultural implements were put to use mainly in the Gorgan and Khuzistan plains.

Crops.—In order of importance the cereal crops grown are wheat, barley and rice. The most important wheat-growing districts are the Reza'iyeh plains in Azerbaijan, the Quchan-Meshed plains in northern Khurasan, and areas in the Kermanshah, Isfahan, Fars and Kerman districts. Wheat is usually sown in the autumn and harvested in the spring, either as an irrigated or rain-fed crop; in the valleys and intramontane plains it is more usually an irrigated crop sown in the spring and harvested in the summer. The average yield is low—less than 1,000 lb. per acre, as against about 2,000 lb. in Great Britain—although in especially favoured regions more than 1,800 lb. per acre has been recorded. Barley is grown in the same areas and in the same way as wheat but is harvested a little earlier; the yield is somewhat higher. Rice is the principal crop of the Caspian provinces, where the climate, unsuitable for wheat, is favourable for rice. It is grown elsewhere on a small scale wherever there is sufficient water. The fields are plowed in winter or early spring and flooded at the end of April. The seed is sown in May and the crop is harvested in August or September. The average yield is slightly more than 1,000 lb. of husked rice per acre. Small quantities of millet (sorghum) and some maize (corn) are grown.

Beans, French beans, lentils, onions, tomatoes, carrots, peas,

cucumbers and most vegetables found in temperate and subtropical climates are grown both as summer and winter crops, generally irrigated. Potatoes were introduced at the beginning of the 19th century by Sir John Malcolm.

There is an exportable surplus of raisins, almonds and apricots; excellent peaches, apples, cherries, figs, dates, olives, oranges, lemons, grapes and melons are also grown. Nuts are found in many districts; pistachios and walnuts are particularly good. Citrus fruits are grown at Shiraz and on the Caspian coast, the estimated crop being about 100,000 metric tons annually. Melons and watermelons are grown in most districts; Isfahan melons are famous. There are many varieties of grape and wine is made in many parts of the country. Dates are a staple food on the Persian gulf and Makran coast. The production of noncitrus fruits has been estimated at more than 1,000,000 tons a year, and between 10,000 and 12,000 tons of dried apricots, nearly 60,000 tons of raisins, 4,000 tons of pistachios and 8,000 tons of shelled almonds are produced annually.

Cotton is the most important of the industrial crops. It is grown by irrigation in many areas, particularly in Azerbaijan, Teheran, Mazanderan, Khurasan, Kermanshah, Fars and Khuzistan. Production of ginned cotton in the early 1960s fluctuated between 70,000 and 90,000 metric tons, a higher output than before World War II. Three types are grown: Filistani, a long-staple cotton; American short staple; and a local short staple, which is hardier than the other two. Silk is produced by the breeding of silkworms in the Caspian coast area. Sugar beets, the growing of which was encouraged by Reza Shah, are an important crop. They are grown mainly in Khurasan, near Meshed; round Teheran; and in the Kermanshah and Shiraz areas. Cane sugar is an old but neglected crop. Jute is indigenous to Mazanderan but the production is low. Tea is a comparatively recent introduction; plantations were developed in Lahijan and the area rose after 1932 from about 700 ac. to 24,000 ac. Production is about 8,000 tons. Tobacco is extensively grown. The entire crop is purchased by the government and processed by the tobacco monopoly. The high production figure of 1,000 lb. per acre has been claimed. The cultivation of the opium poppy was prohibited in 1946–47; the order was enforced vigorously and production has virtually ceased. Gum tragacanth is collected in the hill country from Kerman to Kermanshah, gum arabic near Shiraz and elsewhere.

Livestock.—The most important livestock are sheep and goats, which are not only the principal means of subsistence for the nomadic tribesmen but the chief suppliers of milk and meat to the peasants, who derive most of their cash income from the sale of animal products. Wool is the raw material of the carpet industry, lambskins from the karakul flocks are an important export, and tribal tents are made from goats' hair. Though sheep and goats are found everywhere the largest numbers are raised by the tribes who depend on the seasonal vegetation in the mountain pastures. Good natural grazing land is uncommon and it is probable that the country is overstocked and that controlled grazing and the growing of special grazing crops will be necessary if serious soil erosion, already threatening, is to be checked. Cattle are of increasing importance because of the rising consumption of milk and milk products in the towns. The general quality of dairy cows is low, but in Sarab (Azerbaijan) and Golpayegan two good breeds have been produced. With help from the U.S. Technical Co-operation mission an extensive livestock improvement program has been laid down. Oxen are largely used for draft purposes. Horses are of three types: the Turkoman in the north, the Arab in the south and a cross between the two which is the common Persian breed. Mules and asses are used primarily for transport purposes. Mules (chiefly bred in the southeast, in Luristan, Kurdistan and the Bakhtiari country) are not large but can carry 350 lb. or even more at a good pace 30 mi. in a day. The donkeys are also sturdy and can carry up to 200 lb. Both are also used as draft animals. Camels are still widely employed in the waterless areas of central and southeastern Iran. Poultry are found in nearly every village and particularly in the north where they are of increasing importance as food for the peasants and in the dependent urban areas.

2. Forests.—It is estimated that 44,000,000 ac. or about 11% of the total area of Iran is forest land, which may be divided into four main groups. The most important, though not the largest (8,000,000 ac.), is the Caspian forest, extending along the Caspian coast and the seaward slopes of the Elburz chain to northeastern Azerbaijan. About half consists of dense forest of high quality. In the whole area it has been estimated that there is a growing stock of 315,000,000 cu.m. of timber. The second group comprises the oak forests of the Zagros mountains, stretching from Kurdistan in the northwest through Luristan to eastern Fars and covering about 25,000,000 ac. Only about one-tenth of this is dense and productive forest; the remainder is open forest of low grade. The limestone forests of the northeast stretch from Bojnurd to the southeastern slopes of the Elburz; the principal tree is the juniper but small maples and hawthorn are also found. From Khurasan to Kerman and northern Fars is a scattered group of pistachio forests with wild (inedible) almonds. Other important groups are the small subtropical forests in the Persian gulf-Makran area and desert forests of scrub round the Dasht-e Kavir and the Dasht-e Lut. Much damage has resulted from grazing sheep and goats, from charcoal burning and other human depredations. A forestry organization was established in 1949 whose functions are forest administration, including education and research; establishment of forest and timber industries; demarcation and survey; and the purchase of wastelands for reafforestation. (*See* also *Vegetation,* above.)

3. Fisheries.—Although several thousand persons are engaged in the fishing industry in the Persian gulf, the industry is quite unorganized and production figures are not available. Much of the fish caught is consumed fresh in the coastal areas but there is an appreciable export trade in dried and salted fish to Iraq, India and Arabia. The fishing on the southern coast of the Caspian sea with the two bays of Pahlavi and Gorgan was from 1928 to 1952 in the hands of the Société Mahie Iran, a joint Iranian-Soviet concern. In Jan. 1953 Iran refused to renew the concession. A government company was formed. The annual catch averages more than 3,500 tons (including 150 tons of caviar). In 1956 a joint Iranian-Japanese concern was formed to exploit the Persian gulf fisheries.

4. Mining.—Iran possesses extensive mineral resources. A mining law of 1952 reserved exploitation of deposits of hydrocarbons and radioactive materials to the state; other categories of minerals could be developed by either governmental or private enterprise. In 1938–39 the only mineral export, apart from petroleum, was 6,000 tons of red oxide. Great impetus was given to the mining industry by exploration carried out under the seven-year plan. Red oxide, sulfur, salt, copper, chromite, lead and iron ores amounting to more than 100,000 tons annually were exported in the early 1960s. Projects include the development of the iron deposits at Shamsabad and the coal (now exceeding 170,000 metric tons annually) in Kerman.

Oil.—Eratosthenes of Alexandria (*c.* 276–194 B.C.) appears to have been the first to mention petroleum or its allied products in the region of the Persian gulf and later travelers recorded its existence in Persia. The first project for its exploitation dates from 1896 when the shah granted a concession for a small area in the province of Mazanderan to a Persian. This was acquired by a Georgian adventurer named Khostaria in 1916. Meanwhile William Knox D'Arcy in 1901 obtained a concession covering 480,000 sq.mi. which was afterward transferred to the Anglo-Persian (Anglo-Iranian) Oil company (A.I.O.C.). This concession was canceled by the shah in 1932 but a new concession covering 100,000 sq.mi. in southwestern Iran was signed in 1933 with a period of 60 years. In 1944 the Iranian government decided to postpone consideration of all further oil concessions until after the war. A written promise was given by the prime minister to the Soviet government in 1946 to introduce a bill permitting the formation of a Soviet-Iranian oil company to exploit the resources of northern Iran, but the bill was rejected in 1947 by the *majlis.* The movement against the foreign exploitation of Iranian oil was then directed against the A.I.O.C., a supplemental agreement which would have given additional benefits to Iran was rejected and the 1933 concession was canceled in 1951, in spite of a clause in it

which stipulated that arbitration should be sought in case of any dispute between the company and the government. A bill for the nationalization of the oil industry was passed and the National Iranian Oil company (N.I.O.C.) was set up to take over the A.I.O.C.'s interests. All British employees of the company were withdrawn in Sept. 1951.

Under the earlier A.I.O.C. concession the royalties to the Iranian government varied within fairly wide limits. During the nine years ending in 1928 they averaged £708,000. In 1929 they were £1,437,000, in 1930 £1,288,000, but in 1931 they dropped to £306,872, an amount which the government would not accept; this led to the cancelation of the concession and its replacement by that of 1933.

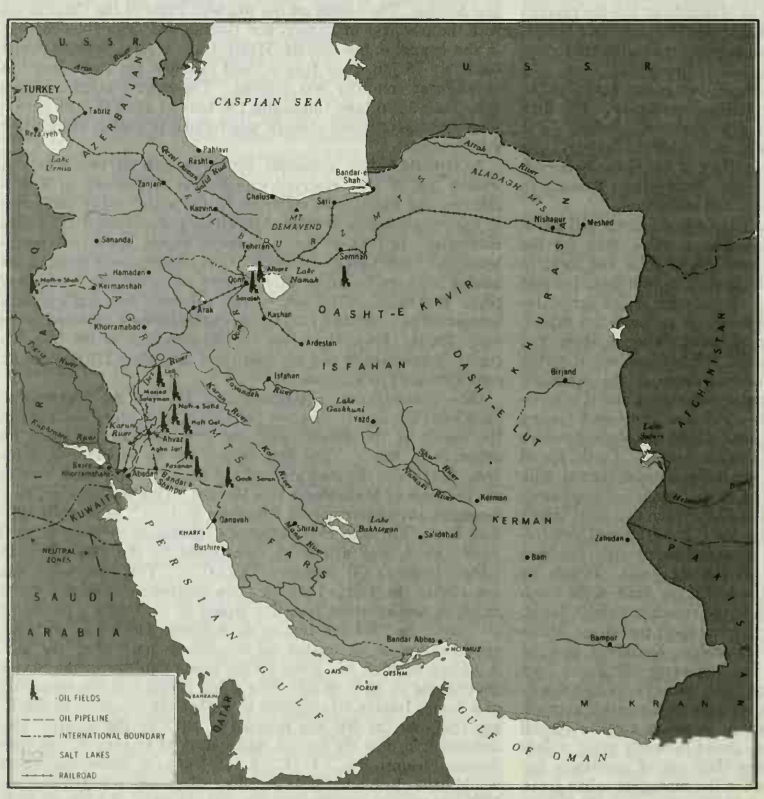
The output of crude oil rose from 83,000 metric tons in 1913 to 7,200,000 metric tons in 1933. During World War II it dropped to 6,705,000 metric tons (1941) but in 1949 reached 27,247,933 metric tons. Under the National Iranian Oil company's administration production and refining were greatly reduced and exports practically ceased. In Oct. 1954, an international consortium of eight oil companies (later joined by nine others) reached an agreement with the government which promised the revival of the industry (*see* PERSIAN HISTORY). The annual production of crude oil then increased from about 16,000,000 metric tons in 1955 to more than 50,000,000 in the early 1960s; revenue to the Iranian government increased from £32,200,000 to over £100,000,000 in the same period.

The oil operations organization of the N.I.O.C. has carried out extensive prospecting all over the country and a fairly detailed geological map of Iran was produced. The Alborz oil field (southwest of Teheran) was discovered in Aug. 1956, when well no. 5 struck oil and went out of control at the approximate rate of 80,000 lb. a day. Sarajeh gas field (40 km. S.E. of Alborz oil field) was discovered in Feb. 1959.

In 1955 the N.I.O.C. signed contracts with British and French firms for a ten-inch products pipeline from the southern oil fields to Teheran (920 km.). This was completed in 1960. Extensions of this line to Shahrud, in the east, and Rasht, in Gilan province, were under construction, as was the pipeline between the southern oil fields and Shiraz.

The terminal for loading crude oil on Jazireh-ye Khark (Khark Island) on the Persian gulf, 23 mi. from the mainland, was opened in 1960. The oil is carried by pipeline overland from Gach Saran to Ganaveh and undersea to Khark where tankers up to 50,000 tons can be loaded at the jetty.

5. Industry.—Out of a population of nearly 20,000,000 the number of industrial workers in the early 1960s was more than 200,000 plus an estimated 200,000 engaged in the carpet industry, in hand-loom weaving and in the hand production of hosiery and knitwear. Thus, although the development of industry was much encouraged by Reza Shah, whose aim was to make Persia self-sufficient in some measure, industry is still much less important than agriculture. Although most modern industry is artificial, in the sense that it was deliberately created by the government, it depends in the main upon indigenous raw materials and was able from the first to draw upon some existing technical skill. Most of the industries started by Reza Shah were grouped under the Industrial and Mining bank, which was, in effect, a holding corporation and an industrial bank, which controlled more than 100 factories and a number of mines. This bank was liquidated in 1949 and all its industries with their assets and liabilities were taken over by the seven-year plan organization and reorganized into groups under specialized corporations. In 1959 most plan organization companies and factories were transferred to the ministry of industry and mines.



PRINCIPAL TOWNS, OIL FIELDS, PIPELINES AND RAILROADS IN IRAN

Textiles.—The majority of textile mills, excluding Teheran, are located in the Isfahan and Mazanderan areas. Production of cotton fabrics, estimated at 70,000,000 m. in 1948, had more than doubled by the early 1960s, and by the mid-1960s Iran would approach self-sufficiency in respect to cotton goods. The woolen industry produces more than 3,000,000 m. of cloth and about 700,000 blankets annually.

Government-owned jute factories in Shahi produce chatai, sack lengths, matting and rope. The Silk Industry corporation was established under the seven-year plan organization to encourage the production of natural silk on the Caspian coast, thus reviving an industry which had flourished in the 17th and 18th centuries. At Rasht there is a breeding station and a silk-reeling plant which could handle about 250 tons of cocoons a year; there is also a silk-reeling and weaving plant at Chalus. The total yearly capacity is estimated at about 1,000,000 m. of fabric and 30,000 pairs of stockings. Annual production of silk cloth exceeds 600,000 m.

Carpets.—Although the de-

mands of the export trade caused some reduction in the artistic standard of Persian carpets, this deterioration applied mainly to the "factories" established by foreign dealers. In them the carpets are still hand-woven but the design is modified to suit the country of import, the weave is usually looser and the nap is left longer than in the finer products. Carpets of the finest design, colour and texture as still made by the tribes and in the traditional centres of manufacture, the districts of Tabriz, Hamadan, Bijar, Sanandaj, Soltanabad, Kashan, Shiraz and Kerman. World demand has fallen and the industry is no longer so important in the Iranian economy as in the mid-1920s when 10,000 metric tons of carpets were exported annually; in the early 1960s the average was 5,000–6,000 metric tons. (*See* also RUGS AND CARPETS.)

TABLE II.—*Direction of Trade*
(in per cent)

Country	Imports				Exports			
	1937–38	1946–47	1954–55	1960–61	1937–38	1946–47	1954–55	1960–61

*Federal Republic of Germany.

Food Processing.—The ministry of customs and monopolies (created in 1958) is in charge of all government rice cleaning and tea plants. There are also numerous privately owned plants, located mostly in the Caspian region. The total tea output of the country increased from 4,000 tons in the early 1950s to more than 6,000 tons in the early 1960s. Sugar refining is mainly government controlled; production, 20,000 tons in the mid-1940s, has increased fivefold. Flour mills are all privately owned. Food canning, vegetable oil, pasteurized milk (in Teheran) and non-alcoholic drink industries were also established.

Cement.—The Building Materials corporation owns a cement factory near Teheran. Other factories were added and cement production increased from 27,000 tons in 1946 to more than 400,000 tons in the early 1960s. There is a refractory brick factory at Aminabad.

Power.—Electric power in Iran falls short of meeting the demand and costs are high. Capacity should be greatly increased by many projects, including hydroelectric plants planned or under construction. By the early 1960s about 100 municipal power plants were completed out of 180 planned. Untapped natural gas from the oil fields is a potential of industrial power.

Other Industries.—By the early 1960s other industrial establishments included an army munitions plant near Teheran with both chemical works and machine shops. The glass industry flourished under private ownership. There are also tanneries, soap and oil-extraction plants, a match industry (which fills local demand and exports to neighbouring countries) and cardboard and paper factories. Craft industries, for which Iran has been renowned for many centuries, continue to exist: the cotton printing of Isfahan; the pottery, mosaic, faïence and tilework of Isfahan; the *repoussé* and carved silverwork of Shiraz, Zanjan and Isfahan; the wood carving of Abadeh and Golpayegan. In spite of the influence toward commercialization which the import of foreign machine-made goods has upon these national industries, the creative instinct and pride of craftsmanship are by no means extinct.

B. TRADE AND FINANCE

1. Trade.—The domestic market system is not well developed. Because of lack of transport, storage and credit facilities there is no easy flow of commodities between producers or importers and consumers, and there is always a great divergence between wholesale and retail prices. In towns the bazaar, both a wholesale and retail institution, is the principal point of assembly, storage and breaking of bulk. It is departmentalized to a striking degree, retailers specializing in one kind of goods concentrated in one section of it. In Teheran department stores are beginning to appear. In villages a few shops or peddlers supply the needs of a scattered population in sugar, tea, cotton piece goods, kerosene, cigarettes, etc.

Foreign trade.—In Iran this is carried out under the following regulations: the government exercises control over normal import and export trade and holds monopoly control concerning the export and import of important commodities. Private traders and agencies, however, may be authorized to import and export these goods subject to the payment of special taxes. Consequently most foreign trade is centred upon Teheran. Trading conditions have become more stable since the rule of Reza Shah, and since the introduction of measures of control the country has maintained a precarious but favourable balance of trade.

The principal exports (apart from petroleum products) are fruit and dried fruit, rice, skins and hides, wool and hair, animal casings, cotton, gums, oilseed, minerals and carpets. Main imports are sugar, tea, coffee, cocoa, paper and cardboard, silk, cotton and woolen textiles, iron and steel, copper and brass (manufactured), machinery and machine tools, electrical apparatus and motor vehicles (including parts and accessories). Imports in general greatly exceed exports.

The main direction of trade is shown in the table, excluding duty free imports (by the National Iranian Oil company, government departments, etc.) and oil exported by the N.I.O.C. or fish exported by the Caspian sea fisheries.

2. Currency and Weights and Measures.—The legal monetary unit is the rial, the nominal equivalent of the older kran, which it superseded in March 1932. The rial, which is subdivided into 100 dinars, at first had a value of 0.07322382 g. of fine gold but in May 1957 its value was legally set at 0.0117316 g. of gold. Officially 100 rials make a pahlavi and its gold content corresponds with that of the old British sovereign. The pahlavi is minted but issued at the market price (about 90 rials in the early 1960s) each Nauruz (Persian New Year). In 1944 silver coinage was authorized and 1-, 2-, 5-, and 10-rial pieces were issued. There are also notes for 10, 20, 50, 100 and 200 rials issued by the Bank Melli Iran. The equivalents of the old and the new currency are 1 shahi = 5 dinars; 1 kran = 1 rial; 10 tomans = 1 pahlavi. A sum of 10 rials is in common usage still referred to as a toman, the equivalent in the old currency of 10 krans.

The metric system of weights has been officially adopted but in the country districts old local standards still prevail. The principal of these are: the gareh (a little more than 6.35 cm. or 2.5 in.) as the unit of linear measure; the farsakh (the distance a laden horse or mule could cover in one hour, about 3.88 mi.) as the unit for long distances; the jarib (rather more than 1,000 sq.m. or $\frac{1}{4}$ ac.) as the unit of area; the kharvar (about 650 lb., or 300 kg., a donkey load) as the unit of weight.

3. Banking.—The banking system was introduced into Persia in 1888 when the New Oriental Banking corporation of India opened branches in the principal towns. In the following year a concession for the establishment of a state bank was granted to an English group under Baron Paul Julius von Reuter, which took over the business of the corporation. The Imperial Bank of Persia, thus formed, had the right of issuing bank notes in the Persian currency to a total value of £800,000. Its name was changed to the British Bank of Iran and the Middle East in 1949. In 1952 all branches in Iran were closed down.

A Russian bank, a subsidiary of the Russian State bank, was founded in 1889 but this Persian branch, with all its assets and liabilities, was transferred by the Soviet government to Persia in 1921 and became the Bank-e-Iran. In 1925 a new Soviet bank, the Russo-Persian, was established to encourage mutual trade.

In 1930 the right to issue notes was transferred from the Imperial Bank of Persia to the Persian national bank, the Bank Melli Iran, which had been founded in 1927, with capital derived from

the value of the crown jewels and domains and other government assets including the Bank-e-Iran. The Bank Melli now has many branches and agencies throughout the country. In 1943 the issue department of the bank and its accounts were separated from the banking department. In 1934 at least 60% of the notes issued were to be covered by gold or silver coins and bullion. In 1940 the value of the crown jewels was counted to make up the deficit when an increase in the note issue was authorized. The currency law of 1954 provided that at least 40% of the cover for notes issued must be in gold or foreign exchange convertible into gold, subject to a minimum gold cover of 35% of the note issue. Iran's gold subscription to the International Monetary fund, to the capital stock of the International bank and to the International Finance corporation, together with foreign exchange and government liability, is secured by the crown jewels.

Other banks are the Bank Keshavarzi Iran (Agricultural bank) and the Bank Sakhtemani (Construction bank) which branched off from the Bank Melli Iran in 1952, and the Bank Rahni Iran (Mortgage bank), which was founded in 1939, finances building construction. The Bank Sepah (founded 1926) deals mainly in inland exchange and holds army pension funds. The first privately owned bank, the Bank Bazargani Iran (the Commercial bank), was registered in 1950.

By the early 1960s there had been a rapid increase in the number of banking establishments. There are now 26 banks; of these 8 are government-owned, 9 are private, 8 have mixed capital and 1 is foreign. Bank Markazi Iran was established in May 1960 by law. It functions as a central bank controlling monetary policy, compiling financial statistics, issuing exchange regulations and providing a clearinghouse.

4. Public Finance.—The bulk of the revenue is derived from indirect taxes (because of their ease of collection). Up to the year 1941–42 efforts were made to balance the budget, and loans from the Bank Melli were confined to those necessary for financing development and productive projects. The disruptions caused by World War II caused a fall in revenue and an increase in expenditure so that the government debt to the bank, which in March 1940 was 1,986,000,000 rials, had increased to about 4,936,000,000 rials by March 1946. In March 1954 it had reached over 17,000,000,000 rials owing partly to the loss of the oil revenue. By 1960 the budget deficit had been reduced to 1.1% and the government debt to the bank had been cut down to 4,750,000,000 rials. In the early 1960s the budget estimates ran at more than 80,000,000,000 rials for both revenue and expenditure.

C. Communications

1. Railways.—Until 1927 when work on the new railway system was begun, no railway construction had been undertaken except a five-mile line from Teheran to the shrine of Abdul Azim which was completed in 1887 and an extension of the Russian system from Jolfa to Tabriz built in 1916. (This finally became Persian property in 1935.) Reza Shah decided for political and economic reasons to create a railway system which would comprise four main lines: (1) a north–south line from Bandar-e Shah on the Caspian through Teheran to Bandar-e Shahpur on the Persian gulf; (2) a northwest line from Teheran to Tabriz to connect with the Russian line to Jolfa; (3) a northeast line to link Teheran with Meshed with possible extensions beyond; and (4) a southeast line from Qom to Kerman. Work on the Trans-Iranian (north–south) was begun in 1927 and the line was opened for traffic in 1938. The total length in the mid-1960s was approximately 860 mi.

The Teheran–Tabriz (463 mi.) and Teheran–Meshed (507 mi.) lines were in operation in the mid-1960s. The connection of Teheran to Tabriz had brought Teheran within reach of Europe by rail through the old Tabriz–Jolfa (91 mi.) line. On the southeast line the section between Qom and Kashan was completed by 1957 but by the early 1960s construction work on the remainder of the line had progressed. The gauge of all these lines is standard except the Tabriz–Jolfa line which is five feet. Locomotives are diesel.

2. Roads.—The important land routes which passed through Persia linking east with west in ancient times fell into decay with the opening of the seas to navigation. The Safawid shahs restored the road system in the north and west during the 16th and 17th centuries but it was not maintained, and natural obstacles and tribal unrest made travel in Persia a precarious and dangerous undertaking. These conditions persisted until World War I when roads fit for light motor traffic were built by the Russian and British armies in the northwest, southwest and east. When Reza Shah came to power, however, there were still only two main routes suitable for motor traffic (Teheran to the Iraq border at Qasr-e Shirin and Teheran to Shiraz), totaling less than 1,200 mi. and indifferently surfaced. As a part of his policy of centralization and tribal control Reza Shah initiated a plan of road construction in which appreciable progress had been made by 1939. During World War II the important supply routes were further developed and improved by the occupying forces, although there was some deterioration afterward. Under the seven-year plan, however, a scheme was started which aimed to reconstruct, or build by linking existing sections, six principal north–south and six principal east–west roads connecting the main cities of Iran and aggregating nearly 8,000 mi.

3. Inland Waterways.—The only navigable river of importance is the Karun, which is navigable by light vessels between Khorramshahr and Ahvaz (112 mi.), below which are rapids that are negotiable only with difficulty during the low-water season (August to November). Above Ahvaz it is navigable again almost to Shushtar. The river is used by vessels of the A.I.O.C. and there is also a separate service from Khorramshahr to Ahvaz.

4. Seaports.—Khorramshahr (*q.v.*) is the principal port at the head of the Persian gulf. It is situated on the north bank of the Shatt al Arab at its confluence with the Karun. The depth of the channel is from 2½ to 3 fathoms. A branch of the railway connects the port with Ahvaz. The port of Bandar-e Shahpur was erected after the construction of the railway by the reclamation of a mud flat in the Khowr-e Musa about 45 mi. from the sea. It was designed by Reza Shah to give an all-Persian outlet for the railway, the Shatt al Arab being in Iraqi territory. Abadan on the Shatt al Arab was the principal oil port of the A.I.O.C. Bandar-e Ma'shur on an extension of the Khowr-e Musa is also an oil port of importance. Bushire is an ancient port about 140 mi. S. of the mouth of the Shatt al Arab. It was formerly the principal point of entry for the Isfahan and Shiraz areas but has lost much of its trade. Ships anchor from three to seven miles offshore and cargo is discharged by lighter. Other Persian gulf and Gulf of Oman ports frequented by trading dhows and pearling vessels are Lengeh, Jask and Chah Bahar.

Pahlavi (*q.v.*) was the principal Caspian port for many years but it is now not greatly used. Bandar-e Shah was built in 1926 as the terminal of the railway but both this port and Now Shahr are subject to much silting. All Caspian ports were extensively used during World War II. In 1958 the administration general of ports was transferred from the ministry of roads to that of customs and monopolies.

5. Civil Airports.—The principal airports are at Teheran (Mehrabad) and Abadan. There are smaller airfields at all the principal towns. The main international airlines have services to Teheran. Iranian National Airways maintains internal air services as well as services to Pakistan and middle east countries.

6. Posts and Telecommunications.—These are administered by the ministry of posts, telegraphs and telephones (P.T.T.). The telegraph line from Tabriz through Teheran to Bushire was formerly part of the Indo-European system which connected London and India. The line now forms part of the national system which covers most of the country. Outlying districts are being brought into the network by radio. Long-distance telephone land lines were constructed by the Allied armies and later taken over by the government. They link Teheran with the southwest oil-field area, the main ports in the Persian gulf and Iraq. One follows the Trans-Iranian railway through Qom and Ahvaz to Bandar-e Shahpur, Khorramshahr and thence to Basra; the other follows the main highway through Kazvin, Hamadan and Kermanshah to Baghdad. There is no national radiotelephone network but international communication by telephone is available from Teheran to

most parts of Europe and the British Isles and, by relay through Bern, Switz., with the United States. There is also a point-to-point service with Karachi, Pak. Radiotelegraphic communication is available to all parts of the world. Radio broadcasting is operated and maintained by the ministry of P.T.T.; programs are handled by the department of propaganda and information. There is limited television programming from Teheran by Television Iran and the U.S. Armed Forces Radio and Television service; a third station was inaugurated in 1961 at Abadan.

Postal services are under the general post office department of the ministry of P.T.T.; mail is distributed by motor truck contractors to places not directly served by the railway. There are regular airmail services to principal cities and military planes serve the southern posts and towns where surface communications are inadequate. *See* also references under "Iran" in the Index.

IRANIAN LANGUAGES. The Iranian languages, of which the Persian branch is the most important, belong to the Indo-European (*q.v.*) family, within which Old Iranian and Sanskrit (*see* SANSKRIT LANGUAGE) form the Aryan group (the terms Aryan and Iran having a common origin). How close Old Iranian is to Sanskrit may be judged from the translation into Sanskrit of the Avestan phrase *yō vō āpō vayuhiš yazāitē ahurāniš ahurahe vahištābyō zaoθrābyō* ("he who worships you, the good waters, the Ahurian [daughters] of Ahura, with the best libations"), which becomes *yō vō āpō vasvīs yajātē asurānis asurasya vasisthabhyō hōtrābhyō;* and the original Avestan words, undisguised by the alphabet, would be still nearer to the Sanskrit.

The principal phonetic distinctions of Iranian from Indian are as follows: (1) original *s* becomes *h* in Iranian; (2) Iranian voiced stops or spirants correspond respectively to Indian voiced and voiceless aspirates; (3) Iranian has *z*, absent in Indian; (4) Iranian diphthongs *ai, au* are found in Indian as *ē, ō,* etc. Examples are given in the accompanying table. Later on the two branches, Iranian and Indian, diverged widely.

Sanskrit	Avestan	Old Persian	Modern Persian
Sindhu (Indus)	*Hindu*	*Hindu*	*Hind*
Asura Medhās	*Ahura Mazdāh*	*Ahuramazdā*	*Hurmuzd*
bhūmi (earth)	*būmi*	*būmi*	*būm*
kratu (insight)	*xratu*		*xirad*
hasta- (hand)	*zasta-*	*dasta-*	*dast*
açva- (horse)	*aspa-*	*asa-*	*asp*

Three successive stages in the history of the Iranian languages, typified by Ancient, Middle and Modern Persian, the principal branch of the group, correspond with successive national vicissitudes. Old Persian was used on the monuments of the Achaemenid dynasty (6th–4th centuries B.C.) destroyed by Alexander the Great. Middle Persian is known from the Parthian or Arsacid period (2nd century B.C.–3rd century A.D.) and more abundantly from the Sasanian epoch (*c.* A.D. 224–651) terminated by the Arab conquest and domination. With the Persian renaissance (9th century A.D.) Modern Persian appears. It changed little thereafter and is still alive. Other Iranian idioms passed through stages similar to those of Persian.

Ancient Iranian Languages.—Of the Median language are known only loan words in Old Persian and, from Herodotus, the word for "dog" (*spaka*), besides several personal names. Of the Old Saka-Scythian group of languages (Scythian and Sarmatian) only personal names in Greek inscriptions, found in south Russia, have come down. The only ancient Iranian languages really known are Avestan (*see* AVESTA) and Old Persian.

The former is the language of the Zoroastrian sacred books. By early European scholars it was improperly called Zend, a term designating only the commentary to the Avesta, written in the form of Middle Persian called Pahlavi (*see* below and PAHLAVI LANGUAGE). The age of the Avesta is dubious. Two parts of it are clearly distinct: the so-called Gathas are more or less at the same linguistic stage as the most ancient Vedic hymns of Old Indian. These archaic poems composed by the prophet of Iran, Zoroaster (*q.v.*), are authentic documents of his religious reform. The greater part of the Avesta, the so-called recent or younger Avesta, is a collection of texts of varying antiquity and is characterized by a gradual simplification and a lax use of grammatical forms. In its present state it is the size of the *Iliad* and *Odyssey* combined. At the time of its codification (4th–6th centuries A.D.) Avestan had long been a dead language known to the priests alone. Its original home is uncertain but must no doubt be sought in eastern Iran. It was long taken for the language of Bactria, but later arguments were advanced for localizing it in ancient Khwarizm (Khiva). The Avestan alphabet was evolved from the late Pahlavi script; before this, the Avestan texts are thought to have been transmitted orally.

Old Persian was used in the cuneiform inscriptions of the Achaemenid kings. The text is usually accompanied by translations into Elamite and Akkadian (Assyro-Babylonian). The most important document is the famous inscription of Darius the Great (reigned 522–486 B.C.) on the rock of Bisitun (Behistun), near Kermanshah, which was first read and published by Sir Henry Rawlinson in 1846.

Middle Iranian.—This term describes the state of Iranian languages from the 3rd to the 10th century A.D., although in the case of Persian the transition from the Middle to the Modern phase must have been completed by the 8th century. The Middle Iranian languages are Parthian, Middle Persian, Bactrian, Khwarazmian, Sogdian and Saka. Linguistically all except the second are closer to Avestan than to Old Persian.

Parthian was the official language of the Arsacid period. More than 2,000 Parthian ostraca, largely records of wine deliveries dated in the 1st century B.C., have been recovered from the site of Nisa, one of the Arsacid capitals (near present-day Ashkhabad). Otherwise Parthian is attested chiefly in later, Sasanian, inscriptions and in Manichaean texts. The Parthian hymn cycles composed by the Manichaean missionary Mar Ammo in the second half of the 3rd century A.D. rank among the highest literary achievements of the Middle Iranian period.

Middle Persian, the official language of the Sasanians, is found in their inscriptions as well as in Manichaean and Zoroastrian books. Of the former by far the most important is the great inscription (*c.* A.D. 262) of Shapur I, a historical record of the war against the Romans, with parallel versions in Parthian and Greek.

The Middle Persian Manichaean literature (3rd–10th centuries) shares with the Parthian and Sogdian Manichaean texts the advan-

tage of being written in an easily readable Aramaic alphabet, whereas the Zoroastrian books (largely commentaries on the Avesta and treatises on religious subjects, composed down to the 9th century) are written in the highly ambiguous Pahlavi script and abound in Semitic ideograms. The extant Pahlavi literature has been computed to amount to 628,000 words (E. W. West). The Manichaean texts, discovered in central Asia at the beginning of the 20th century, are much less numerous but have shed much light on the reading of Pahlavi books.

The first specimen of the Bactrian language, recorded in Greek letters, comes from an inscription of the 2nd century A.D., which was discovered in northern Afghanistan in 1957.

Khwarazmian is found only in glosses and sentences imbedded in medieval Islamic law books.

Sogdian, the native language of the province centred on Samarkand, is available in three distinct Semitic alphabets, one being employed for lay documents and for Buddhist texts, one for Christian and the third for Manichaean literature. Each group, moreover, is characterized by dialectal variations. Sogdian traders and missionaries, traveling and settling in colonies along the route connecting Sogdiana with China, raised their language to the status of a lingua franca of central Asia between the 4th and the 10th centuries. A great deal of Sogdian literature was still awaiting publication at mid-20th century.

Saka is known in two varieties. One, richly attested, was once the language of the kingdom of Khotan in Chinese Turkistan and hence is known as Khotanese. The other (of which only one Buddhist fragment survives) was connected with Tumshuq, also in Chinese Turkistan. (*See* SAKA.) Phonologically, the Iranian language which is closest to Khotanese is the present-day Wakhi in the Pamirs. The amount of Khotanese literature that has been recovered (largely Buddhist, but including some documents of lay content) is hardly less than what has survived in Pahlavi. The language is permeated with Indian elements. The study of Khotanese, still in its initial stage in the 1960s, seemed bound to have a profound effect on philologists' understanding of Iranian in all its branches.

Modern Languages.—All Iranian languages now used display some tendency toward an analytic stage (simplification of the sounds and, in morphology, the use of new auxiliary tenses, etc.). Of these languages by far the most important is literary Persian, as found in the extensive Persian literature and among educated speakers.

Modern Persian is a direct descendant of Middle Persian, but has borrowed many words from a source akin to Parthian, and contains numerous Arabic and Turkish elements. It is written in Arabic characters. Though Modern Persian is a single language, local variations spoken in Iran, Afghanistan, India and Russian Turkistan (Tadzhik S.S.R.) are considerable.

Dialects, parallel to literary Persian, are used in most Iranian towns and villages. The dialects of Fars, Luristan, Khurasan and Kerman belong to the same southern group as the literary language. On the other hand, numerous other vernaculars represent the remains of former northwestern idioms.

Such are the local dialects of the Caspian provinces, the language of the Kurds (spread over a vast area and sporadically found in northern Syria and even close to Ankara in Asia Minor), the language of the Balochis (*see* BALOCHI LANGUAGE) and the tongues of isolated groups (such as those of Kashan, Simnan, etc.).

Among Modern Iranian languages of the eastern group are the Afghan language, Pashto (*q.v.*) or Pushto, the various dialects of the Pamir group (Shughni, Wakhi, Munjani, etc.), Yaghnobi (a modern descendant of Sogdian) and Ossetic (*see* OSSETIC LANGUAGE), spoken in the heart of the Caucasian mountains south of Ordzhonikidze (Vladikavkaz), a survivor of the once powerful Sarmatian group of Saka spoken in south Russia.

See also references under "Iranian Languages" in the Index.

BIBLIOGRAPHY.—Detailed monographs on most Iranian languages, with a bibliography complete to the end of the 19th century, will be found in vol. i of *Grundriss der iranischen Philologie*, ed. by W. Geiger and E. Kuhn (part i, 1895–1901; part ii, 1898–1901; supplement on Ossetic, 1903). Its modern, more succinct counterpart is *Handbuch der Orientalistik*, vol. iv (*Iranistik*), part 1 (*Linguistik*), ed. by B. Spuler (1958). For the Old Iranian languages *see:* C. Bartholomae, *Altiranisches Wörterbuch* (1904), *Zum altiranischen Wörterbuch* (1906); R. G. Kent, *Old Persian* (1950). Middle Persian and Parthian texts have been edited by W. B. H. Henning from 1932 onward; *see* also A. Ghilain, *Essai sur la langue parthe* (1939); and Mary Boyce, *The Manichaean Hymn-Cycles in Parthian* (1954). For a selection of Parthian ostraca *see* I. M. Diakonov and V. A. Livshits, *Dokumenty iz Nizy* (25th International Congress of Orientalists, Moscow [1960]). For Shapur's inscription *see* M. Sprengling, *Third Century Iran, Sapor and Kartir* (1953). For Bactrian inscriptions *see* W. B. H. Henning, *Bull. Sch. Orient. (and Afr.) Stud. Lond. Univ.*, xxiii (1960). Other inscriptions: *Corpus Inscriptionum Iranicarum* (London, 1955–). For Khwarazmian *see* A. A. Freiman, *The Khorezmian Language* (in Russian, 1951). Sogdian texts have been published by F. W. K. Müller, W. Lentz, R. Gauthiot, E. Benveniste, W. B. H. Henning and O. Hansen; *see* Ilya Gershevitch, *A Grammar of Manichean Sogdian* (1954). V. A. Livshits has been publishing Sogdian documents from the Samarkand region since 1959. Khotanese texts have been edited chiefly by E. and M. Leumann, S. Konow and Sir Harold Bailey; *see* for instance H. W. Bailey, *Khotanese Texts*, vol. iv (1961). For the languages spoken in Afghanistan and the Pamirs *see* G. A. Grierson, *Linguistic Survey of India*, vol. x (1921); G. Morgenstierne, *An Etymological Vocabulary of Pashto* (1927), *Indo-Iranian Frontier Languages*, 2 vol. (1929, 1938); on Ossetic *see* V. I. Abayev, *Ossetic Language and Folklore* (1949), *Ossetic Etymological Dictionary* (1958–), both in Russian. For Modern Persian and Kurdish dialects *see* O. Mann and K. Hadank, *Kurdischpersische Forschungen*, 7 vol. (1906–30); D. N. MacKenzie, *Kurdish Dialect Studies*, 2 vol. (1961–62); A. Christensen, *Contributions à la dialectologie iranienne*, 2 vol. (1930–35); B. V. Miller, *The Talyshi Language* (in Russian, 1953).

The best theoretical grammar of Modern Persian is C. Salemann and V. A. Zhukovsky, *Persische Grammatik* (1889). More practical are D. C. Phillott, *Higher Persian Grammar* (1919), and Ann K. S. Lambton, *Persian Grammar* (1953). Dictionaries include: J. A. Vullers, *Lexicon persico-latinum*, 2 vol. and an annex (1855), complete and important for research work; Baron J. J. P. Desmaisons, *Dictionnaire persan-français*, 4 vol. (1908–14); S. Haïm, *New Persian-English Dictionary*, 2 vol. (1934–36), *New English-Persian Dictionary*, 2 vol. (1929–31). (V. F. M.; IA. G.)

IRANIAN LITERATURE: *see* PERSIAN LITERATURE.

IRAQ (AL JUMHURIYAH AL 'IRAQIYAH or AL 'IRAQ), an independent country of southwest Asia and a republic since 1958, is bounded north by Turkey, east by Iran, southeast by the Persian gulf, south by Kuwait and Saudi Arabia, and west by Jordan and Syria. Its area is 169,284 sq.mi. and population (1962 est.) 6,802,843. It comprises the three former Turkish provinces (*vilayetler*) of Basra, Baghdad and Mosul (*qq.v.*). The frontiers were agreed and delimited between 1922–37; until 1926 it was uncertain whether the Mosul region would form part of Turkey. In the north and much of the east, the frontiers follow natural features in difficult hill country with few routes. There is however one comparatively easy route via Kermanshah to central Iran. Toward the head of the Persian gulf the Iraq-Iran frontier is arbitrary, and the entire Shatt al Arab is included in Iraq. The western and southern frontiers are again arbitrary—straight lines drawn between a few outstanding natural features.

I. PHYSICAL GEOGRAPHY

1. Geology and Structure.—Iraq consists of a lowland trough lying between asymmetrical and very different upland massifs to the east, north and west, and continuing southeastward as the Persian gulf. The region is one of crustal weakness and subsidence, with relatively young and plastic sedimentary rocks engulfed and downwarped between (on the west) the ancient, rigid and highly resistant block of Syria-Arabia and (east and north) the highly folded and topographically imposing younger Zagros and Anatolian mountain chains. The Zagros folds are mainly immense anticlines or hogbacks running from northwest to southeast with great regularity, and rising abruptly from the flat low-lying riverine plain. The Iraq-Iran political frontier follows this well-defined physical boundary for only about 250 mi.; farther south, Iranian territory extends westward to include a stretch of lowland at the head of the Persian gulf, while toward the northeast the frontier swings east into the Zagros formation, thus including an extensive hill territory within Iraq. On the northwest and west, the land rises more gradually and regularly into the plateau of Syria-Arabia, which consists of a mass of Archean granites overlain by sedimentary layers, chiefly of the Mesozoic (Jurassic and Cretaceous) and Cenozoic (Eocene and Miocene) periods. Slight tilting or differential erosion have produced minor topographical features and the western edge of the Euphrates valley is in some places marked by a discernible cliff (*iraq*) from which the name of the country is said to originate. In the extreme northwest there are several small and gentle but clearly defined folds, which appear as ridges aligned more or less in an east–west direction, the chief of which is the Jabal Sinjar near Mosul.

2. Relief and Drainage.—The fundamental elements in the physiography are the twin valleys of the Tigris and Euphrates (*qq.v.*) rivers, joined in the south, but diverging in the north, separated by a tongue of higher land stretching southward from the Anatolian foothills to just north of Baghdad, and known as Al Jazirah ("the island"). Like Egypt, Iraq is very largely the gift of its rivers; and a consideration of both rivers is an essential basis to understanding the geography of the country.

Both rivers rise in the eastern highlands of Asia Minor, and pursue an intricate course southward around the numerous east–west aligned mountain ridges. In places, earth movements and the emission of lava have greatly affected their course; *e.g.*, the lava flow from Karacali Dag near Malatya has diverted the Euphrates to the southwest. Both rivers also flow at times in enormous gorges cut directly across the fold ridges, and it is inferred that the folds may have developed subsequent to the drainage pattern. Emerging from the Anatolian mountains into the upland country of Syria and Kurdistan, they have cut normal narrow valleys into the plateau surface and dropped considerably in level. Between the Turkish frontier and the Baghdad region, the Euphrates falls by about 800 ft. (1:3,000) and the Tigris by 1,000 ft. (1:1,750), hence both streams are swift and heavily charged with sediment at all seasons. In the region of Baghdad there is a sharp change: from there the valleys are extremely flat—Baghdad itself is only 110 ft. above sea level. Northward from the head of the Shatt al Arab, where the two rivers may be said to merge, there is a fall of only 8 ft. in 100 mi. To explain this somewhat unusual pattern two theories have been evolved. The earlier, postulated by J. de Morgan, is that at one time the Persian gulf extended as far as the Baghdad area. Two smaller rivers, the Karun and the Kharkeh, both of which are relatively large in volume and swift (owing to rapid descent from the Zagros mountains) then emptied directly into the Persian gulf, and in so doing rapidly built out deltas toward the south. Ultimately these deltas extended entirely across the gulf to its southern shore, thereby cutting off the Tigris-Euphrates system from the open sea and the scouring effects of currents. In consequence, the Tigris and Euphrates deposited huge quantities of silt and mud which gradually filled in the head of the gulf, and dried out to form a low, irregular land surface, with the head of the gulf rapidly receding toward the southeast; a rate of two miles per century has been suggested. As substantiating evidence, De Morgan invoked (1) the presence of a low but prominent ridge 250 ft. high running across the river valleys from Ramadi to a point a few miles southeast of Baghdad; this, he suggested, was the old coastline of the gulf; (2) the remarkable flatness of the lower valleys of both rivers, with a succession of river channel, marsh flats and sandy-ridges; and (3) the undoubted changes of coastline within historic time in the configuration of the gulf coastline around Basra.

In 1952 the validity of this view was challenged by G. M. Lees and N. L. Falcon (*Geogr. J.*, vol. cxviii, March 1952), who demonstrated that in the past 100 years in some areas there had been no significant advance of the coastline toward the southeast; that at Basra the alluvial deposits lie directly upon land-formed rock series and not, as would be expected, upon strata showing a former marine incursion; and lastly, that the historic changes in land and coastal forms may have been less than at first supposed. They therefore postulate a more stable coastline, roughly at its present day position, with the accumulation of silt from the rivers producing a downwarping of the land surface in order to accommodate increasing weight. As the land surface sank there would at first be temporary hollows which gradually filled up through the deposition of alluvium and also by the "trapping" and "fixing" of wind-borne dust by water surfaces. Discussion still continues, with inconclusive results in favour of either theory.

Regime of the Euphrates and Tigris.—Both rivers are at their lowest in September and October, and as temperatures fall, evaporation is markedly reduced, leading to an increased flow from November in the Euphrates, though not in the Tigris, which being narrower and deeper is less affected. In spring the melting of snows in the Anatolian and Zagros mountains produces flooding, with a maximum level in April (Tigris) and May (Euphrates). This difference is due to earlier melt in the more southerly Zagros, and also to the character of underlying rock strata: the western Zagros include many impermeable layers from which runoff is rapid, while in the Euphrates basin there is much porous limestone through which meltwater percolates relatively slowly. The Euphrates rises by 11 ft. at Hit, and its flow increases from 8,800 to 64,300 cu.ft. per second; and the Tigris by 18 ft. with, at Baghdad, a normal increase in volume from 11,900 to 106,650 cu.ft. per second. There are important differences in the two rivers. After leaving its mountain area, the Euphrates receives only two left-bank tributaries, the Belikh and Khabur; there are no right-bank tributaries. Consequently, there is much loss by evaporation during passage through the Syrian steppe and lowlands of Iraq. The Tigris, on the contrary, though devoid of right-bank tributaries, flows parallel to the Zagros ranges, from which it receives many affluents, including the Great and Little Zab, Diyala and Karun. The Tigris therefore not only carries far more water but is also subject to much more sudden flooding, since its catchment area is wider, and local rainfall can have a greater effect—it may rise by 10–20 ft. in one day. Another feature common to both rivers but more developed on the Tigris is the formation of natural embankments, or levees, in the lower valley. This phenomenon, characteristic of many silt-charged rivers flowing over flat plains, *e.g.*, the Mississippi in the U.S. and the Yellow river in China, gradually raises the river bed above the level of the surrounding plain, and tributaries thus enter with difficulty, often forming a marshy or flooded area near the confluence. Another feature is that if flooding destroys the bank of a natural levee, the river may develop an entirely new course. This has happened on many occasions in the past on both rivers; *e.g.*, the mainstream of the Euphrates flowed past Hillah in the early 19th century, but 100 years later had shifted to a new channel just east of Najaf. In the lower valley therefore there are many old channels, some dry, some occupied by distributary streams which lead off water from the main course, and others now used for irrigation. Because of the extreme flatness many thousands of square miles in lower Iraq are regularly

flooded from 10 to 20 ft. deep. Settlements, roads and railways are therefore sited on natural or artificial mounds. Baghdad in particular has been subjected to devastating floods, especially in 1954; but with the completion of river control projects, including that of the Wadi ath Tharthar, flooding has been greatly reduced in the north.

3. Geographical Subregions.—It is possible to distinguish on a physiographic basis four major subregions: lower Iraq, made up of the twin lowland of the Euphrates and Tigris rivers; upper Iraq, the now separated river valleys with an intervening plateau zone; Assyria and Iraqi Kurdistan; and the western desert region.

Lower Iraq or the *Lower Valley* (sometimes referred to as the delta lowlands) begins at the ridge between Ramadi and Baghdad and extends about 350 mi. southward to the Persian gulf. The Tigris and Euphrates diverge respectively east and west below Baghdad, which is therefore in a narrower waist of lowland. The Tigris has a particularly tortuous course; between Baghdad and Kut the distance by river (213 mi.) is about twice that by road. This stretch of the river is marked by large numbers of old meander channels, some cut off to form oxbow lakes. Because of the natural levees and the difficult entry for tributary streams there is much marsh. Many subsidiary rivers empty into the Suwayqiyah depression, and navigation of the mainstream is difficult because of the sharp bends and strong current. Below Kut the course of the Tigris is much straighter, with a flatter slope (1:29,000 as compared with 1:15,000) and this allows free-flow irrigation on a large scale—a more difficult matter above Kut. The Tigris has shifted its course several times in the last 1,500 years: between the 8th and 16th centuries it flowed in what is now the Shatt al Gharraf. In its lowest section, especially from 'Amarah southward, the waters are dispersed into distributary channels and marshes, both east and west; only 19% of the flow at Baghdad passes down the main (navigable) channel from 'Amarah to Al Qurnah.

From Ramadi southward the Euphrates flows at first in a well-defined channel, about 150–300 yd. wide and of low season depth, 3–7 ft. Natural levees occur, as on the Tigris. Between Al Musayyib and As Samawah the river discharges into various distributaries, and in early Arab times formed one enormous swamp, with many present-day remnant features: old channels, levees, cutoffs and lakes. From As Samawah there is a well-defined channel as far as Nasiriyah, or even Suq ash Shuyukh, lying within an open plain which is now largely arid and almost featureless. Below Nasiriyah distributary channels (natural and also man-made) take off the whole of the Euphrates water, which ultimately drains into Lake Hammar, a vast expanse of reedy swamp, only 2–3 ft. deep in places. From Al Qurnah, the point of junction between the waters of Lake Hammar and the Tigris, the river is known as the Shatt al Arab.

Away from the rivers patches of swamp and marsh occur with irregular ridges between. Parts are still largely uninhabited and unsurveyed; in other areas are communities of Marsh Arabs, who live in reed and brushwood huts set often on brushwood foundations, and who subsist on rice, fish and *ageyl* (an edible species of rush). Along the river there is much variation in the quality of the land; some parts have infertile sands and gravels while others have alluvium and clay which when watered can be highly productive.

Upper Iraq.—This comprises the valleys of the two main rivers, together with the tongue of irregular and somewhat higher ground which stretches southeastward between them as a prolongation of the Syrian steppe. At its entry into Iraq the Euphrates has cut a broad flat valley about 10–12 mi. wide, and because of the absence of tributaries the sides are generally steep. Rejuvenation of the Euphrates led to many meanders being incised into the flat floor, giving a second set of terraces, with the river about 150–500 yd. wide. Irregularities in rock strata have produced rapids and shoals, and the river tends to hug the western bank, producing a marked escarpment on the west, and more open country to the east. The Tigris on leaving Turkey has cut an irregular winding passage among low foothills and ridges: in places it runs parallel to the strike of these folds (mainly northwest-southeast) but elsewhere it cuts directly southward by narrow gorges through the hills themselves. Hence the upper Tigris has something of an alternation in topography; where the river flows southeastward it tends to have a wide, shallow bed, with steep-sided hills on the western (right) bank, and open rolling country to the east. Separating these reaches are north-south running defiles, the narrowest of which is at Baghloja, about 18 mi. below the confluence with the Iraqi Khabur, where the Tigris is only 40 yd. wide, with a series of rapids which are almost cascades. Such conditions continue as far as Mosul, after which relief becomes much less accentuated, ultimately falling away to open steppe through which the Tigris flows in a broader channel marked by shingle deposits. There the Tigris is joined by the Great and Little Zab rivers; the latter, though small in volume, being liable to rapid flooding. One last, isolated, defile occurs where the river breaks through the Jabal Hamrin above Ba'iji at a gorge which is now used to carry the oil pipelines from Kirkuk to the Mediterranean. From Tikrit southward the Tigris wanders on a flat plain, breaking up into several arms, with the beginning of some of the features developed to a greater degree below Baghdad; at least two major changes of course have occurred.

Between the Euphrates and Tigris, and bounded on the north by the Jabal Sinjar lies Al Jazirah, a region of undulating steppe, small-scale fold ranges and closed drainage basins. The steppe continues into Syria and Jordan with the fold structures arranged in an arc running from west to southeast. The warping of the whole area has produced closed drainage basins, the largest of which is the Wadi ath Tharthar (a long defile running more or less parallel to the Tigris about 30 mi. farther west) which was important as a grazing area and is now part of the Tigris flood control project.

Assyria and Iraqi Kurdistan.—Fronting the Tigris on the east between the Turkish frontier and the broad Diyala valley is an upland area roughly rectangular in shape which rises in steps eastward from river level. The first step is the Jabal Hamrin (1,600 ft.), and behind it lies an undulating territory of river basins, rolling plateaus and irregular hills which ultimately pass into the main Zagros range. The lower (western) part, broken by the valleys of the Great and Little Zab, is the ancient region of Assyria (*q.v.*); farther east, as the mountain zone begins, there is an alternation of high ridges aligned northwest–southeast, with river basins between.

The plain of Mosul is drained mainly by the Great Zab and consists of irregular steppe rising from about 700 to 2,000 ft. A rich heavy soil made this plain the granary and centre of ancient Assyria, with its capitals of Nineveh, Nimrud and Khorsabad. The zone between the two Zab rivers (central Assyria) is much less densely settled, partly because of the lack of good water; some springs are brackish and sulfurous. An exception occurs round Irbil, where the soil and water are better; this region still produces the best wheat in Iraq.

In Iraqi Kurdistan, mountain ridges trend generally northwest–southeast, attaining 10,000–11,000 ft. in a few places, with a summit average at about 8,000 ft. Between the ridges are trough valleys (often synclinal) usually occupied by rivers which have eroded out basins. All the streams weave a tortuous way south and southwest toward the lowlands, and are marked by gorge and defile sections (*darband*) where they skirt or cut through ridges. In a few places, *e.g.*, Sulaymaniyah, Al 'Amadiyah, Rawanduz, patches of lowland allow cultivation, but much of Kurdistan is given over to pastoral nomadism. Remoteness and difficulty of access have hindered surveys and development. (*See* also KURDISTAN.)

Western Desert.—Lying to the south and west of the riverine lowlands, this region extends from Kuwait and Saudi Arabia on the south as far as Jordan and Syria. The desert area slopes gently upward from the Euphrates lowland, and is formed of Cretaceous and Tertiary rock series, which are often exposed as irregular pavement. Differential resistance to erosion produces minor relief features, and there has been some small scale tectonic disturbance, hence the surface is by no means uniform or featureless. In the extreme south, the actual frontier with Kuwait is formed by the Wadi al Batin, a rift structure three miles wide running

inland from Zubayr as far as central Arabia. To the north lies Sahra' al Hijarah, in the main a region of shallow mud-lined depressions, rocky outcrops and loose sand, passing, near the Euphrates, into an extensive swamp area.

Farther north lies the Wadian region with steeper slopes. Because of this steepness normal drainage developed again, and there is a network of dry valleys which are aligned northeastward to the Euphrates, and still carry flood water for an hour or two each year. The region takes its name from these valleys (wadies). There is no fringe of continuous sand or salt marsh, as farther south; the Wadian therefore offers more practicable routes westward and has been used from earliest days for transport, and now for oil pipelines.

4. Climate.—Because of the simplicity and regularity of relief, Iraq has a straightforward climatic regime. In the lowlands two contrasting seasons occur: a dry and intensely hot summer (May–October), and a relatively cool, humid winter (December–March) with short transitional periods. In the mountain zones relief exerts a considerable effect, and winters can be moderately severe. From May onward the predominating element is the existence of a semi-permanent zone of extremely low atmospheric pressure, situated at the seaward end of the Persian gulf, and over West Pakistan. This draws in air from the northwest, which produces a very persistent and regular northwesterly wind (*shamal*) over the whole of Iraq. Coming from land areas, these currents are dry, and hardly any cloud forms, so that for several weeks or even months the sun beats down uninterruptedly, producing extremely high temperatures—July and August means are about 35° C. (95° F.), with mean day maxima up to 43° or 49° C. (110° or 120° F.). Some drop is apparent close to water surfaces because of intense evaporation, but the physiological effect is hardly improved because of higher humidity. Strong winds produce blowing dust or sandstorms; July is the worst month, with an average of five storms at Baghdad and eight at Ash Shu'aybah. No rain falls between May and October, the first onset beginning at the end of October, with January–February the wettest period.

During the winter season conditions are more variable. Relatively shallow and transient depressions move eastward from the Mediterranean to the Persian gulf, and give rise to the *sharki*—a cool, damp southeasterly which brings rain and variable weather. At other times a cold air mass from the interior of Asia may extend westward, bringing fine but cold conditions. Hot air masses from the south may also affect Iraq; January temperatures of more than 27° C. (80° F.) are known but frost may occur anywhere, even at Basra, though this is unusual. The northeast has its own climatic conditions, as much as 30–40 in. of rain occur on the highest mountains, with 15–25 in. in Assyria. There are therefore two climatic provinces within Iraq; a hot arid lowland, and the damper northeast where rainfall is sufficient for crop growing, with slightly lower summer temperatures and a colder, continental winter, up to three months of snow lying in some places. Over-all, Assyria and Kurdistan apart, the main features of Iraqi climate are aridity and overwhelming summer heat, the difficulties of which are intensified by high atmospheric humidity locally near the rivers. Lacking in most cases the opportunity to move to higher altitudes, many better-off Iraqis have constructed underground rooms or cellars (*sirdab*) in which to pass the hottest part of the day.

5. Soil Character.—Reflecting the physiographic and climatic divisions of the country, the soils fall into two contrasted groups: heavy alluvial deposits associated with the main rivers, and very light soils in the rest of the country. The alluvial soils contain a significant proportion of humus and clay, and dry out to a hard tenacious mass which can be used for building. The light soils are deficient or entirely lacking in humus, with a low clay content; but they may have a proportion of wind-deposited minerals, some of which are valuable plant nutrients.

For both groups of soils there is an acute problem of salinity induced by watering under conditions of sharply seasonal rainfall followed by a hot arid season. This produces evaporation of soil moisture, and consequent accumulation of alkaline salts at or near the surface, in quantities sufficient to inhibit cultivation. On entering Iraq, the Tigris and Euphrates contain about 30 parts per 100,000 of salts; in their lower courses this proportion has trebled. In 1949 the Haigh commission estimated that 60% of all irrigated land in Iraq had become salinated, and an over-all assessment is that 1% of total cultivated area is abandoned each year because of salinity. Crop yields have fallen by 20%–30% since 1920 with a 50% decline in a few extreme cases. It is now recognized that irrigation itself is not sufficient; there must also be a system of rapid underground drainage to lead away irrigation water after use, before it is evaporated with consequent salination.

6. Vegetation.—Iraq is a meeting place of two major plant groupings, both of which show the predominating influence of drought. Toward the north and east (broadly from latitude 32°–33° N.) there is a steppe vegetation of perennial bushes and low shrubs, with mugwort (*Artemisia*), goosefoot (*Chenopodiaceae*) and grass species dominant, together with a "flush" of short-lived creepers and grasses, which amount to 60%–70% of the total vegetation. Toward the south and west, vegetation is often restricted to thorns (chiefly tamarisk and species of *Haloxylon*, of which *H. persicum* affords useful camel-fodder and fuel), a few shrubs, *e.g.*, rhanterium and papposum, and other salt-resistant plants. Poplar, willow, licorice and tamarisk flourish (usually in small clumps) near the rivers, and below Al Qurnah the marshland is an area of reeds, tall grasses and sedge. Open oak forest occurs on the Zagros mountains between 2,000 and 6,000 ft., now mostly reduced to scrub by intensive cutting and unrestricted grazing; above this is an alpine zone of cushion plants and dwarf species broadly similar to those of alpine Europe. Millions of cultivated date palms produce one of Iraq's most important exports (see *Agriculture*, below).

7. Animal Life.—This has been much reduced: the oryx, ostrich and wild ass are now practically extinct, and the last lion appears to have been killed around 1910. Bats, rats of various species, jackals and wildcats are the most common mammals, with wild pig and gazelle in remoter parts. Reptiles are numerous: lizards (the largest, *Varanus griseus*, reaching four feet); snakes (mainly "racer" species and sand snakes), only three species of which (the horned and blunt-nosed vipers and a rare cobra) are poisonous; and two types of tortoise, of which *Trionyx euphraticus* is peculiar to Iraq. Many kinds of fish occur, including the "Tigris salmon," a barbel which can attain seven feet. Iraq is also visited by vast numbers of migrant birds.

II. THE PEOPLE

There are important racial and cultural distinctions among the population of Iraq, with the major, predominant difference lying between Arab and Kurd. The Arabs are a markedly homogenous group, and occupy most of the centre, west and south of Iraq, where they have probably lived since very early times. Both nomads and settled peoples in these areas are of this basic type; some authorities see a difference in the Marsh Arabs or Madan (*see* ARAB) who may be descended from the ancient Akkadians and Sumerians. The Kurds are racially akin to the Iranians, and form another, smaller homogenous group located mainly in the north and east; they are probably descendants of the Medes. Kurds with their racial associates, the Yezidis and the Assyrians, were estimated in 1961 to number 850,000, or about 12% of the total Iraqi population. Smaller groups are (1) the Turkmen (Turkoman; *q.v.*) who live in communities in Irbil and Sulaymaniyah provinces; (2) the Shabaks of Mosul, who possibly originated in central Asia; and (3) the Mandaeans (*q.v.*), who though distinct as a religious group are less so as a racial element. Until 1948 Iraq had a significant Jewish community, living mainly in the towns; the majority have migrated to Israel. Arabic, the official language, is the most widely spoken. Kurdish and Turkish dialects are common in the north and variants of Iranian are found among the eastern tribes.

Religion divides the people of Iraq. The majority (about 75%) of the Arab population are Shi'ah Muslims, as are 50%–60% of the Kurds; but a minority of Sunni Muslims (about 25% of the Arabs and 40%–50% of the Kurds) have long held effective political dominance. Most tribal chieftains and politicians are Sunnis, a fact which partly explains the disturbed nature of Iraqi

politics. There are also a number of small Christian groups, who live mainly in the north, round Mosul, or in the larger towns: Nestorians (*q.v.*), Jacobites, Chaldeans, Syrian Catholics (*see* ROMAN CATHOLIC CHURCH) and Gregorian Armenians (*see* ARMENIAN CHURCH). They have generally been in political disfavour. Other religious groups are the Yezidis, a Shi'ah offshoot who combine features of several religions; and the Mandaeans, who revere John the Baptist.

Population.—The population of Iraq at the census in 1957 was 6,538,109. It is very unevenly distributed: for the most part the valleys of the two large rivers are relatively densely inhabited, while the deserts of the west and even some area of the riverine lowlands have a scanty population. On a basis of persons per square mile of cultivable land, population is concentrated in four main regions: the banks of the Shatt al Arab; along the middle and upper Tigris around Baghdad and across to the Euphrates at Hillah; the lowland basin round Sulaymaniyah; and the upper Euphrates. By no means all of the great river valleys (especially just north of the Shatt al Arab) are as densely peopled as would be imagined. This is important because, with so much land sparsely populated, there is less incentive to farm it well, and some authorities have suggested that a denser population might result in improved methods of agriculture.

Towns play an important part in Iraq. Baghdad, the capital, is by far the largest; other large towns are Basra, Mosul, Kirkuk and Najaf (*qq.v.*). The rest are spread fairly evenly throughout the riverine areas. Special features of the settlement pattern are: (a) the number and even spread of towns of relatively small size (10,000–25,000 inhabitants); and (b) the extent to which the populations of even large towns are partly agricultural; *i.e.*, there is much less of the sharp distinction between town and country which is characteristic of western countries. Over most of Iraq the occurrence of towns and villages is closely related to water supply from rivers or irrigation canals, but in Assyria and Kurdistan rainfall is sufficient for nonirrigated cultivation, and there is a more uniform spread of settlement over the entire province—in sharp contrast to the rest of Iraq. Nomadism is important not only in the western deserts, but also between the two rivers, both in Al Jazirah and the drier and sandier parts as far south as the Shatt al Gharraf. Nomads are also an important element in the towns, which they frequent in large numbers at certain seasons. Religious pilgrimages to Karbala', Najaf and Samarra' swell the local population; and in Kurdistan seasonal migration (transhumance), mainly from winter (lowland) to summer (upland) pastures, is widely practised. Some Kurdish tribes even cross the frontiers into Iran and Turkey. (W. B. Fr.)

III. HISTORY

For the pre-1914 history of Iraq, *see* MESOPOTAMIA; CALIPHATE; PERSIAN HISTORY; and articles on the former empires (BABYLONIA AND ASSYRIA; TURKEY) of which the territory had formed part.

1. World War I.—The entry of Turkey into World War I in Nov. 1914 led immediately to the dispatch of a small British expeditionary force from India to the head of the Persian gulf. It had three main objectives: to secure Great Britain's unique and valued position in the gulf and to safeguard its friends in that area; to prevent a hostile Turko-German penetration of southern and eastern Persia, such as to threaten India; and to safeguard the infant petroleum industry in southwestern Persia where oil was first produced by the Anglo-Persian Oil company in 1912. The force, collected at Bahrain, landed at and secured Abadan, and occupied Basra (Nov. 22). With increasing local contacts and commitments in the southern areas of the Basra *vilayet*, a rudimentary British civil administration came into existence under the chief political officer, Sir Percy Cox (*see* COX, SIR PERCY).

Turkish counterstrokes having been repulsed, and country-wide river flooding survived, the expeditionary force, enlarged to army corps dimensions, reached upward into lower-Euphrates country as far as Nasiriyah, and up the Tigris to Qurnah and 'Amarah. In the autumn of 1915, however, a bold advance pressed upriver nearly to Baghdad could not be sustained, and resulted in withdrawal to Kut, where the army of Gen. Sir Charles Townshend was surrounded, besieged and finally, after 140 days, in spite of strenuous efforts for its relief, forced to surrender on April 29, 1916. The summer was employed by the British in a thorough overhaul of establishments and communications, under a vigorous commander, Gen. Sir Frederick Stanley Maude. In the winter of 1916–17, after patient preparation, he ousted the Turks from their positions in the Kut area and advanced to the occupation of Baghdad (March 11, 1917) and beyond it, before settling down to a summer of consolidation. Maude died of cholera in Baghdad (Nov. 18, 1917).

Early in 1918, while the occupied territory was already under an improvised but comprehensive civil administration (conducted with admirable devotion, though not without its painful episodes), Maude's successor Gen. Sir W. R. Marshall was able to advance up the Euphrates and to plan a final blow on the Tigris. Late in October he advanced through the Jabal Hamrin, crossed the Tigris and administered a final defeat to the Turks at Kalat Sherghat (Sharqat) a few days before the armistice of Mudros (Oct. 30). Kirkuk was also occupied and then Mosul itself. (*See* also WORLD WAR I.)

2. The Iraqi State.—Two uneasy years followed. The British administration, hampered by the repatriation of key men, by war-weariness, and by uncertain policy, maintained itself in spite of lower-Euphrates Shi'ite intrigues, endemic tribal disorders, the reluctance of the Kurds of the Iraqi northeast to be controlled, and the entry of a stream of Arab-nationalist propaganda from Syria. The last-named element took its place in the Iraq of 1919–20 with echoes of the 19th century yearnings for Arab emancipation, awareness of the real or alleged promises of Arab independent statehood made by Sir Henry MacMahon as high commissioner in Egypt in 1916, the Wilsonian fourteen points (and notably the self-determination principle), and with the specific Anglo-French declaration (Nov. 1918) that Iraq and Syria were to become free, self-determined states. It resulted that, while tribesmen chafed at the exigencies of an efficient and honest regime, the Iraqi intelligentsia demanded, first privately and then openly, an "Arab government" of their own. Converting some leading sheikhs to their view, and noting the wholesale withdrawal of British forces, together with indications that concessions to their views either by Whitehall or the local civil commissioner (Sir Arnold Wilson) were slow and reluctant, they managed in the summer of 1920 to bring about disorders which, except in the principal towns and some quiet areas, upset administration, cost lives, and cut communications (including the new Basra-Baghdad railway) in much of the territory. A major military effort, with the re-entry of important British forces, was needed to restore order, collect arms and punish the recalcitrant. These tasks were accomplished by mid-autumn 1920, Sir Percy Cox returning to Iraq as high commissioner in October.

The general policy to be adopted had by now been settled in London—it was one of Iraqi self-government under British advice and (temporary) control—and a mandate for the territory, awarded to Britain by the Supreme Allied council at San Remo in April 1920, had been accepted. Cox inaugurated an all-Iraqi council of ministers, entrusted departmental and provincial administration to Iraqis under British advice or inspection, founded an Iraqi army—and looked for a king. He was found without difficulty in the person of Amir Faisal (*see* FAISAL I). Driven by the French from his Syrian throne (July 1920), he was encouraged to proceed to Iraq, was there widely acclaimed, and thanks to his personal gifts and wartime fame was elected to the throne by a rough-and-ready but decisive referendum. He was crowned in Baghdad on Aug. 23, 1921; an Iraqi state and monarchy had come into existence.

3. Monarchy Under Mandate.—The British mandate lasted until the autumn of 1932: the monarchy, from 1921 to 1958. The period during which the two institutions ran concurrently was a vitally formative period for the modern Iraqi state. Successive high commissioners—Sir Percy Cox, Sir Henry Dobbs, Sir Gilbert Clayton, Sir Francis Humphrys—were devotedly supported by the comparatively large but diminishing staff of British advisers and experts—ministerial, departmental, regional—engaged by the Iraqi

government, which included some outstanding personalities; and the Iraqi administration, from the council of ministers and headquarter departments to remote outstations, developed and consolidated into a machine of considerable efficiency, with many officials of high merit. Relations between the British and Iraqi elements, too easily perverted to suspicion or worse, were normally preserved on a level of cordial co-operation. The mandate over Iraq, with its solid state-building achievement (and its early relinquishment) was beyond doubt the most successful of the mandatory experiments of the period.

The years 1921–32 showed many interesting features. The administration of the territory was established, and survived regrettable but inevitable incidents of tribal disorder, urban faction and political restlessness. Lawlessness in Kurdistan (which lacked Arab-inspired loyalty), mid-desert Bedouin anarchy and the theocratic recalcitrance of the Shi'ite (largely Persian) mujtahids (religious teachers) of the holy cities were gradually overcome. The Iraqi army and the police grew in efficiency. The monarchy appeared popular, with the king an indispensable element in unifying and inspiring public sentiment. The country in fact settled down to find its own orientation and level of security, and to be governed as a modern state. Its relations with neighbours were various: with Persia, never cordial but never violent; with Arabia, marked by serious frontier raids and bitterness (in which Hashemite-Saudi antipathy played a main part) until a measure of reconciliation was achieved in 1925. The Turks, neighbours and ex-suzerains, demanded at the 1923 Lausanne conference no less than the "return" of the Mosul *vilayet*, or most of it, to Turkey, as being predominantly Turkish in race. This led to the long-drawn "Mosul question" which, after many fruitless meetings at Geneva and Istanbul, and the mission to Iraq in 1925 of a fact-finding League of Nations commission, was decided by the League in favour of Iraq, with preservation of substantially the old *vilayet* boundary as the Iraq-Turkish frontier: a decision which, after initial protest, was loyally accepted by Ankara. The League decided, however, that British control in Iraq must be extended to 25 years.

The British decision to implement its mandate by a suitable Anglo-Iraqi treaty was a shrewd one, though it did not render the unpopular imposition of foreign tutelage either invisible or acceptable. A first treaty, with its attached agreements, was signed in June 1922, subject to ratification by a constituent assembly. The latter was convened in March 1924 and succeeded, in face of much intimidation and reluctance, in ratifying the treaty and passing also an organic law, which endowed the country with the institutions of a limited monarchy and two-chamber parliament. Meanwhile, short-lived Iraqi cabinets came and went, the social services developed and British staffs continued to diminish.

A new Anglo-Iraqi treaty, in 1927, marked some advance, but the desired final step of terminating the mandate was delayed by divergent views on timing and by the interest of other League of Nations members. The years 1927–30 were marked by mutual misunderstanding and impatience, as well as by the normal effervescence of Iraqi domestic politics, by problems of security, the development of new (road, rail and transdesert) communications, and by the discovery in 1927 of an important oil field at Kirkuk. But the 20-year treaty signed in June 1930 laid down an acceptable relationship between the two nations, with minimal British privileges, and provided for Iraqi membership of the League in 1932. This was accepted by the League itself, under strong British sponsorship, and on Oct. 3, 1932, Iraq achieved its ambition of complete independence and League membership.

4. Independence.—The years 1932–39 were uneasy and disappointing. The sudden death of Faisal I in Sept. 1933, a grievous loss, made way for the short and inglorious reign of his pleasure-loving son Ghazi, and the road accident which killed Ghazi in April 1939—followed, in Mosul, by anti-British rioting—passed the throne to Faisal II, a child of three, under the regency of his cousin (and uncle) the young amir Abd-ul-Ilah (*q.v.*). The material development of the country continued; oil production, with its resulting revenues, began actively in 1934; and industry, irrigation, communications and the public services all made progress. British control ceased, and advice at all levels grew rarer. Though one nationalist stalwart, Ja'far al-'Askari, was murdered, the state was served by many devoted ministers and officials, notably Nuri as-Said (*q.v.*), Yasin al-Hashimi, Hikmat Sulaiman and Jamil al-Midfai. New party groupings—although an authentic party system had little progressed—showed the advent of a new left-wing reforming nationalism among the middle-class intelligentsia. Cabinets continued to change rapidly, elections to be largely controlled, personal and class interests, mainly conservative, to be dominant.

A saddening, indeed shocking, episode of the time was the massacre of over 300 Assyrian villagers, at Simail (Sumayyil) in northern Iraq, by an army unit in Aug. 1933, an episode applauded by most Iraqi opinion, and never punished. It was followed by the departure of a large part of the hapless Assyrian community to Syria. A *coup d'état* by the ferocious Gen. Bakr Sidqi in Oct. 1936 was the first of a series of military interventions in the government; and though Bakr himself after some months of power was murdered in Aug. 1937, the evil precedent had been established. This was equally true of the politicians' practice of organizing tribal uprisings (never, in practice, controllable) against the government of their rivals in office.

Anti-British feeling gained ground during this period, largely by natural reaction against former control and through the Iraqi view of events in Palestine. Admiration of Hitler's Germany was shown in close contacts with that country and significant Nazi-type youth movements in Baghdad.

5. World War II.—The war period in Iraq falls into two unequal parts, separated by a single month of abnormal happenings. During the first 20 months from Sept. 1939 the normal restlessness of public life in Baghdad was aggravated not by mobilization or military disturbance but by increasing pressures, ambitions and controversies, and by the beginning of war shortages and economic dislocation. The murder of a minister of finance, Rustum Haidar, set off a long train of inquiries and vendettas; German victories and the fall of France seriously affected the attitude of the dominant army officers, and not least that of the "golden square" of four outstanding Anglophobe generals. In spite of a diplomatic breach with Germany (though not with Italy), a pro-German party, civil and military, formed and consolidated, while increased army pressure bore on successive civilian cabinets. Political strife grew ever bitterer and, after the finally enforced flight of the regent himself from the country, a revolutionary regime under a puppet amir was formed by Rashid Ali al-Gailani as prime minister supported by the "golden square."

In March 1941 the incoming British ambassador—Sir Kinahan Cornwallis, a veteran of the Iraqi administration of 1921–37—found himself at deadlock with the Gailani cabinet over British rights of military transit, for which the treaty of 1930 provided. Relations became critical, British women and children were evacuated, and on April 30, 1941, Anglo-Iraqi hostilities began in earnest at the British air base at Habbaniyah. This "war," highly embarrassing to Great Britain and its allies though waged with little conviction by the Iraqi forces, lasted some 30 days. The German aid expected by the Gailani government came too late and scantily; Iraqi opinion, and even its armed forces, were deeply divided. The attack on the scarcely defensible camp at Habbaniyah was never pressed, and, while all British and some U.S. subjects were confined uncomfortably in the British embassy in Baghdad and elsewhere in the country, light British forces reached the scene of action from Palestine, and others landed from India at Basra. These sufficed to bring about, in a few days, the disintegration and then the flight of the Gailani supporters, followed by the re-establishment of the legitimate regime, and constitutional government, under the returned amir Abd-ul-Ilah. The child-king returned from his Kurdish refuge to Baghdad.

During the remainder of the war period British troops stayed in Iraq, in a purely beneficent and defensive "second occupation" (as it was called by critical Iraqi politicians) until 1945. During this period political life was revived, within limits. Iraq adhered to (indeed, played a major part in) the inter-Arab negotiations at Cairo which produced the Arab league, as well as participating in all the end-of-war international congresses at Hot Springs, Bretton Woods, Chicago and San Francisco. Efforts, not wholly success-

ful, were made by responsible statesmen to restore national unity and self-respect. In spite of varied forms of control, retail prices rose, distress was widespread (though a few war millionaires flourished) and normal economic life was disturbed. The public services and officialdom deteriorated, and national development (including oil production) suffered; but security, except for a persistent nucleus of trouble in Kurdistan, was well maintained. The regent visited Great Britain and the United States, and Iraqi statesmen toured widely among Arab capitals.

6. Postwar Hopes and Distresses.—Once rid of British garrisons and wartime embarrassments, and with legitimacy and a degree of democracy restored, the state might well hope for rapid progress. Able men, though drawn still from a narrow circle, served the government—Hamdi al-Pachachi and his cousin Muzahim, Arshad al-'Umari, Fadhil al-Jamali, Salih Jabr, the Baban brothers Jalal and Jamal, and a dozen more, in addition to the veteran Nuri as-Said (Nuri Pasha), whose 10th premiership was announced in 1949 (and his 13th in 1958). The divorce between cabinet and parliament remained almost complete, still more the gap between parliament and nominal electorate. The regime was ill based and, increasingly year by year, failed to reflect much or most of the views, and the frustrated emotions, of the younger politicians and would-be reformers. The monarchy, with Abdul-Ilah still regent till 1953, was active and influential, with conservative leanings; the king went to complete his English education at Harrow. Reform or improvement in some public services was observable, especially after the shadow of acute financial shortage disappeared in the early 1950s as oil revenues increased. The oil development which produced these was extended, and material progress in many directions was notable. Almost the last of the veteran British advisory corps left between 1945 and 1947, only newly recruited technicians and specialists remaining. A permanent nonpolitical development board was set up in 1950, to spend 70% of oil revenues. Political parties, restarted in 1946, continued till 1954, and tended to coalesce into conservative progovernment and radical antigovernment groups, the latter of which seemed destined for permanent exclusion from power. Communism, ever present above or under ground, was habitually suppressed, especially by Nuri Pasha, but could still exercise attraction and had power to encourage disorder and fan anti-western feeling. The latter attitude, in spite of an explicit (but not uncritical) prowesternism among the ruling clique, constantly gained ground and force among the opposition. British policy in Palestine was a major cause of this. The newspapers by their violence called for frequent measures of discipline or suppression. Political life, in fact, was full of tension and instability, even in periods of apparent tranquillity, and outbreaks of mob violence, often Communist-organized, were unpleasantly common, notably in the capital. Tribal disorder, except for a time in Kurdistan, seemed to be a rarer phenomenon than in earlier years.

Relations with Iran remained strained and suspicious, in spite of a state visit by the regent to Teheran in 1949. With Turkey a friendly treaty was made in 1947, against opposition protests. The Fertile Crescent conception (that is, Iraqi-Syrian-Jordanian union) had its supporters during the period, but came to nothing. Iraqi relations with Egypt were not cordial, those with Saudi Arabia improved. Outspoken support of all Arab objectives was incumbent on every politician, as was hatred of Zionism and the state of Israel. The U.S.S.R., feared as the worst of menaces by Nuri Pasha and his followers, was viewed not without sympathy, or at least with indifference, by the opposition, by whom western Europe and the United States were condemned as reactionary, self-interested, and inimical to Arab ambitions.

Episodes of these years, more important than state visits, official openings of new public works, or the installation and rapid fall of cabinets, included the participation of Iraqi forces in the unsuccessful Arab intervention against newborn Israel in 1948: forces which gave, indeed, a better account of themselves than most of the Arab armies. They were withdrawn in 1949. (The departure to Israel of some five-sixths of Iraq's 150,000 Jews dates from this period.) The Palestine expedition was, by some months, preceded by the signature at Portsmouth by Ernest Bevin, the secretary of state for foreign affairs, and the Iraqi prime minister, Salih Jabr, of a new Anglo-Iraqi treaty (Jan. 1948) to replace that of 1930, which had long been unpopular; but massive and destructive riots in Baghdad, and a timely *volte-face* by the regent, led to the repudiation of the treaty by the Iraqi government and the hasty installation of a neutral caretaker government for some weeks, followed by general elections. Finally, the serious riots of Nov. 1952, starting with minor student grievances but soon transformed into a political demand for single-stage elections to the chamber (long an opposition desideratum), were a damaging blow to public order and confidence. With wholesale hooliganism and loss of police control, they led to the appointment of a leading general, Nureddin Mohammed, as temporary prime minister and, under martial law, to the temporary suppression of political parties. Normal forms of government were restored early in 1953; but it was to no peaceful heritage that the young King Faisal II, straight from Harrow, succeeded on his coronation on May 2. He was 18, small and unimpressive, a sufferer from asthma, but well meaning, dignified and popular. The regent, loyal and affectionate, remained as his chief personal adviser, and became crown prince.

7. Reign of Faisal II (1953–58).—The five-year reign of the young king covered a period of outward peace. There were fair hopes that the now great and increasing resources of the state treasury, derived from augmented oil revenues, would create a sounder and more broadly based national economy in agriculture, industry and commerce, and could thereby provide nonpolitical careers for the underemployed intelligentsia; and that the delights and distractions of an expanding and widely shared material prosperity would neutralize the fairly general "political" resentment known to be felt at the suppression of political parties and the sternly (but on the whole benevolently) authoritarian tone of political life under Nuri Pasha, who enjoyed the complete support of the throne. But this was not to be.

The reign opened with the inauguration of the great 30-in. transdesert oil pipeline from Kirkuk to the Syrian coast, followed unhappily by devastating Tigris floods which inundated the outskirts of Baghdad itself. The king and Nuri visited Pakistan. After some rapid changes of cabinet (without relation to popular or parliamentary feeling) Nuri Pasha assumed office, for the 12th time, at midsummer 1954, this time for three full years. He abolished all political parties, including his own, and imposed his customary strict discipline on political life and the press, with particular severity against the Communists. The excluded politicians, nevertheless, with a fairly large urban following, coalesced increasingly into a dumb but potentially powerful opposition, and sentiment hostile to the regime gained ground, invisibly, even in the army. The monarchical regime, in fact, with its "strong" government, its scant respect for political exuberances, its openly pro-western leaning in international affairs, and its local support mainly from feudal, conservative, upper-class, and satisfied circles, became a minority faction less robust than it appeared.

Nuri Pasha's outspoken anti-Communism was, with his habitual sympathy for Turkey, mainly responsible for the conclusion of a defensive alliance with that country in Feb. 1955. This, joined by Pakistan and Iran, became the Baghdad pact (*q.v.*), and was, in effect, a (not exclusively) military organization designed to safeguard the exposed northern tier of middle eastern nations against the U.S.S.R. The accession to the pact of Great Britain made possible a specific reformulation of the latter's rights, as an ally, at the surviving air base of Habbaniyah. This in turn permitted the politically convenient demise of the existing (1930) Anglo-Iraqi treaty, long an object of opposition-nationalist attack. The pact, which the United States joined as a benevolent "observer," was, however, greeted with the strongest dislike, not only by most of Iraqi, anti-Nuri opinion, but by almost all other Arab countries, notably Egypt, as being an organization faithless to Arab loyalties and too friendly to "imperialism." Iraqi-Egyptian relations as a consequence further deteriorated.

During the crisis of outraged Arab feeling precipitated by the British-French and Israeli action at Suez in Oct.–Nov. 1956, Iraq broke off diplomatic relations with France, and it required all the resolution of Nuri and the palace to prevent a similar en-

forced break with Britain. Anti-western disorders in fact broke out at various centres, and martial law was proclaimed; but the government, which temporarily but pointedly absented itself from Baghdad Pact council meetings attended by Britain, was able to ride the storm. The cessation of oil exports, due to the destruction of the Iraq Petroleum company's pipeline pumping stations by Syrian troops, was a severe, if temporary, financial blow to Iraq.

In 1956–57 an exchange of official visits improved Iraqi-Saudi relations; those with Syria deteriorated and those with Jordan, now clearly threatened by a Syro-Egyptian *rapprochement*, grew ever closer. The membership of successive cabinets in Baghdad rang the changes among Nuri's supporters. The king, in Sept. 1957, announced his engagement to a young Turkish-Egyptian princess.

The integration of the United Arab Republic (of Egypt with Syria) in Feb. 1958 led immediately to the announcement by Iraq and Jordan of a federation known as the Arab Union, which, as a Hashemite defensive move against republicanism, was formulated and brought into existence by a rapid series of conferences and agreements. A federal constitution and government (with Nuri as federal prime minister) came into existence, and general elections were held. But all this, including the Iraqi monarchy itself, was brought to nothing by the sudden and (it appears) unforeseen military revolution of July 14, 1958, led by Gen. Abdul Karim Kassem (or Qasim). Long planned in great secrecy, it was accomplished by a single day of street violence, wholesale arrests, an attack on the British embassy and the bloody "liquidation" of the king, the crown prince and almost the whole royal family—and Nuri Pasha—in circumstances never fully established. Order was thereafter quickly restored, a republic proclaimed under a council of sovereignty, and a revolutionary cabinet of civilians and officers formed, with Kassem as prime minister. The latter declared Iraq to be rid at last of a "corrupt gang imposed on the country by imperialism." The hitherto frustrated politicians and their followers, and doubtless a large part of the urban public, believed the millennium to have arrived. No counterblow, throughout Iraq, was struck. The revolution, received with horror in Jordan, and with doubt in Arabia, was warmly welcomed by the United Arab Republic.

8. Post-revolutionary Period.—The revolution failed to gratify these high hopes. Iraqi relations with the United Arab Republic rapidly deteriorated to extreme bitterness when Kassem's government refused the close bonds with Egypt and Syria which had been expected by pan-Arab optimists, and when Communist influence in Baghdad visibly increased. With Turkey relations were correct, even after Iraq had renounced the Baghdad pact; with Iran they fast deteriorated to the point of angry recriminations and troop movements when Iraq claimed a riverain strip on the Shatt al Arab, which the treaty signed at Sa'dabad in 1937 had ceded to Iran. Diplomatic relations were early established with the U.S.S.R., China and other Communist countries, and with these a series of pacts, trade agreements and missions were exchanged. The Communist element in Baghdad itself appeared, to western eyes, alarmingly prominent. This, and the internal acts of the regime, lost it much of the sympathy of the non-Communist world at large; its credit indeed never stood lower than in the post-revolutionary period of strain, suppression and reprisals. Kassem, fundamentally well meaning, not undemocratically minded and certainly non-Communist, showed little capacity for resolute or constructive action on enlightened lines; he tried, at best, by occasional gestures and utterances, to show a "neutrality" not consistently anti-western.

The political world, in which parties were still prohibited until licensed under an "Association law" in Jan. 1960, rapidly split into two main schools. One, supported by most hitherto excluded "progressive" politicians and returned exiles, favoured Egypt and pan-Arabism; the other, supported by the Kurds and well-organized Communist elements, preferred a more generalized pan-Arabism which reflected deep-seated Iraqi-Egyptian—and perhaps Nasser-Kassem—jealousies. Early differences and an alleged "plot" within the revolutionary ruling clique itself led to the deposition of Col. Abdul Salam 'Arif, Rashid Ali al-Gailani and other leading personalities, the resignation of cabinet ministers and the arrest of scores of old-regime high officials and statesmen. This gravely weakened the administration, and the conduct of the Communist-inspired military (or "people's") court trying these offenders, and condemning a number to death, brought much discredit on it.

The suppression of a short-lived military uprising in Mosul in March 1959, apparently in the Baathist or Nasserite interest, increased the Communist ascendancy; but demands for more Communist privileges, and their direct representation in the cabinet, were rejected by Kassem, and savage rioting in Kirkuk in July was attributed by the leader (who later, however, reversed his judgment) to their adherents. Four old-regime officials (including men of outstanding merit), and nine officers implicated in the Mosul rising, were put to death in September. Scores of further arrests followed an attempted assassination of Kassem in Oct. 1959; he was wounded, and retired for two months to a hospital; and amid the habitual and envenomed Cairo–Baghdad wireless and press polemics, "Nasserite agents" were generally blamed. The trial of suspects began late in December, the death penalty being demanded for some 100 individuals, in some cases in their absence. In March 1960 a number of death sentences were commuted to terms of imprisonment.

In the economic field, insecurity, restrictions, censorship and loss of public confidence were inhibiting factors. Works of development, for which treasury allotments were reduced from 70% to 50% of the oil revenues, slowed down, though an ambitious £400,000,000 program was published. The ministry of development was abolished. Land reform, confidently announced, made appreciable progress in some areas, but with varying results on the scale and efficiency of cultivation. Soviet contractors and experts multiplied, often in replacement of British. Varying pressures were brought to bear on the oil companies, but the work of these (except for the foreclosure of one minor concession) was not interrupted, and by their efforts oil production increased. Iraq left the sterling area, alleging nonpolitical reasons.

A serious revolt which broke out in Kurdistan in March 1961 continued throughout the year. It was suppressed with great severity, but incomplete success. On June 25, 1961, a few days after Great Britain had recognized the sovereignty and full independence of Kuwait, Kassem laid claim to the entire territory of the oil-rich amirate as an integral part of Iraq. At the request of the amir British troops were immediately sent to strengthen the defenses of Kuwait. This was sufficient to deter the Iraqi army from intervention, but later in the year Kassem repeated his claim to the territory. The admission of the sovereign amirate to the Arab league led to Iraq's abstention from its meetings. Further protracted negotiations with the Iraq Petroleum company and its subsidiaries ended in failure in October. The companies were thereupon deprived of the greater part of their concession areas, requests for statutory arbitration being ignored (see *Oil*, below).

An end to Kassem's repressive, eccentric dictatorship came with a long-planned coup by "free officers," mainly of the Baath Socialist party, on Feb. 8, 1963. This was followed by the execution immediately of Kassem and later of dozens of known Communists. The authors of the revolution, the National Council for the Revolutionary Command, pledged themselves to honour Iraq's foreign and industrial obligations and installed a seemingly capable team of ministers. Col. Abdul Salam 'Arif, Kassem's former deputy, became president of the republic. Plans for social, agricultural and industrial reform were published, though "security" absorbed most of ministerial time. Relations with the oil companies improved. Claims to Kuwait were, by implication, dropped. Relations with the U.S.S.R. markedly deteriorated, and Iraq's outspoken antimonarchism offended Jordan and Saudi Arabia while drawing it closer to (also Baathist) Syria. The western powers all recognized the new regime. Early cordiality with Egypt led to Iraq's inclusion, in April, in the plan for a wider U.A.R. to comprise Egypt, Syria and Iraq. It was clearly destined to be dominated by Nasser, but Baathist antipathy to some features of this union caused the Baghdad government, after *ad hoc* ministerial

changes, to cool visibly toward the project. On Nov. 18, 1963, President 'Arif and a team of generals seized power from the cabinet of Baath socialists. 'Arif indicated that he would co-operate closely with all Arab nations, especially the U.A.R. (S. H. Lo.)

IV. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—Iraq was for long a dependency of the Ottoman empire, though not fully brought into the central system of administration; thus while Turkish rule left a considerable imprint on some aspects of life, others were much less affected, and Iraq was far from being fully assimilated. After World War I and a period of British military government, a constitutional monarchy was set up in 1921, with the Hashemite Faisal I as king. The constitution was revised in 1924, and in 1932 the British mandate ended and Iraq became a fully sovereign state. Dynastic difficulties followed the death of Faisal I in 1933, his younger son Abd-ul-Ilah acting as regent for his young nephew (who became King Faisal II in 1953). This period was characterized by the growing influence of the army in political life, and by the development of a system of government under which, though democratic in theory, the real power lay in the hands of a few high officials, wealthy townsfolk, and tribal and religious leaders. The increasing unpopularity of the government led by the regent and his prime minister, Nuri as-Said, culminated in the military coup of 1958 which brought an end to the monarchy and gave power to the army group backed by Gen. Abdul Karim Kassem (who was in turn overthrown in 1963 by Colonel 'Arif [see *History*, above]). The 1924 constitution was annulled and a provisional constitution proclaimed on July 27, 1958, provided for the establishment of Iraq as an independent, sovereign and Islamic republic. Under the 1924 constitution, provision existed for popularly elected assemblies, with adult male suffrage; but this machinery was not always satisfactorily used under the monarchy or up to the mid-1960s by the "national revolutionary council."

By the 1924 constitution Iraq was divided into *liwa's* (provinces), each administered by a *mutasarrif* (governor). The settled and desert *liwa's* were subdivided into a varying number of *qadhas* and *nahyahs* under *qaimmaquams* and *mudirs* respectively. By 1960 the three desert *liwa's* (then designated as territories) had been distributed administratively among certain of the 14 settled *liwa's*. (*See* Table I.) The administration of the country is exercised by the government through the *liwa's;* the *mutasarrif* is responsible to the minister of the interior and also represents other ministries, though these may have their own representatives on the *liwa'* councils, which include some elected members. The *liwa'* council has a right to a share of local taxes and may also receive government grants for particular projects.

TABLE I.—*Administrative Divisions and Desert Territories*

Liwa's	Area (sq.mi.)	Pop. (1960 enumeration)
'Amarah	6,929	349,799
Irbil	5,913	281,367
Baghdad	7,692	1,411,693
Basra	6,958	542,660
Diwaniyah	42,753	520,757
Diyala	6,078	349,677
Hillah	2,660	376,213
Karbala'	2,619	237,319
Kirkuk	7,546	417,656
Kut	5,720	303,553
Mosul	19,645	756,482
Nasiriyah (formerly Muntafiq)	5,580	468,954
Ramadi (formerly Dulaym)	53,270	249,429
Sulaymaniyah	4,631	313,881
Desert territories*		
Northern Desert	39,127	—
Southern Desert	29,399	—
Al Jazirah	12,056	—

*The areas of these territories are also included in the areas of the *liwa's* above.

One long-standing problem has been the position of minority groups. The chief of these, the Kurds, have shown some nationalist feeling, aiming at uniting into one territory the peoples of Kurdish culture who are now scattered within Iran, Turkey, Syria and Iraq, and number probably 4,000,000–5,000,000—larger than the populations of several sovereign middle eastern states. From time to time Kurdish nationalist feeling has been a source of discord, e.g., with Iran and Turkey, and of internal weakness which could be exploited by outside powers such as the U.S.S.R.

2. Social Conditions.—A survey in Iraq during 1956 indicated that the average peasant annual income in cash and kind amounted to £14–20 per family. This is about the average within the middle east generally—slightly lower than in Egypt and Syria, but higher than in Arabia and Iran. A number of factors are responsible for this, some of which derive from the physiographic environment, others from purely social conditions. Of the former group, climate, irregular flooding and difficulties with soil fertility are the chief, and there is also a high incidence of disease, affecting humans, plants or animals. Three great afflictions in Iraq are malaria, parasitic infestation—chiefly schistosomiasis (bilharziasis) and ancylostomiasis (hookworm)—and dysentery. It is an unfortunate fact that often with an increase in irrigation, malaria and parasitic infestation also spread; and there are a few parts of riverine Iraq where 50%–70% of the total population are affected, though the situation is better than in Egypt.

Oppressive social conditions depress the living standards of many Iraqis. Heavy rents and taxes may absorb as much as 60%–85% of the total produce of an agricultural holding; a survey in southern Iraq by D. Warriner in the late 1950s showed that in many instances a peasant had to pay taxes to the government, rents to the principal landowner, to minor subtenants and to local overseers, and dues for irrigation water, leaving him with only 20% of all that he produced. Most land in Iraq is owned by wealthy townspeople, whose social and economic position was greatly strengthened after World War I; partly because under modern laws an entire tribal territory may be registered in the name of one leading individual, who comes to be regarded as sole owner; and partly because of the restricted outlets for capital investment within the middle east. Land with a settled cultivating peasantry is often purchased as an investment, to produce a fixed return on capital; hence an owner may discourage initiative; he is content to receive the fixed income and does not risk experiment or further investment in long-term improvement. The peasant, often suffering from debilitating disease, has neither the ability to plan nor the energy to initiate improvements, even were he permitted to do so; thus low resultant yields remain characteristic. Conditions in Iraq, more than in some other middle eastern countries, favour the wealthier classes rather than the small cultivator; flood control, dyking, marketing of produce abroad can be undertaken by an individual possessing capital, who can afford to wait for his return, but not by an underfed peasant totally dependent for existence upon the next harvest. As a result, Iraq has shown to a high degree a social unbalance: great disparity of wealth and poverty, much land held by absentees, and tribal patriarchal authority transforming itself into economic dominance, while at the same time divesting itself of social responsibility to those from whom its wealth is derived. The 1958 revolution is thus not hard to explain; and one of its principal results was an important program of land reform and redistribution, which by the early 1960s affected about 500,000 ac. Of this, a certain proportion represented genuine transfer from landlord to peasant; but, as in other middle eastern countries, there have also been collusive transfers which leave real ownership untouched.

The growing contrast between an archaic countryside and developing towns has produced in the mid-20th century a second social phenomenon in Iraq: a considerable migration into, and expansion of, the towns. Most of the increased wealth is spent or displayed in the towns, which thus offer a strong attraction to the more intelligent peasant; Baghdad grew by 50,000 annually during the 1950s and doubled in size during the same period. The *Iraq Times* stated in 1956 that in some areas more than 80% of the total rural population had migrated to the towns; and many of these live as squatters, in huts made of reeds, mud or flattened gasoline cans, with few or no amenities. This explosive development of town life brings political as well as social problems. The growth

of a rootless, underprivileged town proletariat, by no means always employed, adds yet another dangerous element to the already perilous social mixture in Iraq.

On the other hand, the growth of an educated middle class may prove a stabilizing factor. In 1947 only 8.5% of the Iraqi population was regarded as literate; but since then education has considerably expanded. The emergence of technically trained persons is not only essential if the wealth of Iraq is to increase, but highly desirable on political grounds. A high birth rate (30–33 per 1,000), and a low death rate (8–12 per 1,000) strikingly reduced during the mid-20th century, means that population is increasing by about 2.5% annually, and thus could double in less than 50 years. With only 20% of potentially cultivable land in use, and a relatively assured income from oil royalties for a number of years, this population surge can be accommodated (one of the few middle eastern territories where this is now the case), but development depends on a favourable political situation.

Of a total working population of approximately 2,000,000, it was estimated that 1,560,000 were farmers or herders (160,000 nomadic); 105,000 in industry (14,000 in the oil fields and refining); 200,000 in commerce; 55,000 in transport; 20,000 in catering trades; and the remainder in professional or government service. Women would seem to provide 25%–30% of the labour force in agriculture, and 15% in industry. Under the monarchy organized labour was virtually nonexistent. The announced policy of the republican government was the encouragement of trade unions, and by the early 1960s the General Federation of Labour Unions claimed 50 affiliated unions and a membership of 250,000. The General Federation of Peasant Societies, founded 1959, claimed more than 730 affiliated societies.

3. Welfare.—Iraqi life has a certain dualism; in some respects ways have changed little since Ottoman days when sharp class distinction, with extreme poverty the lot of the majority, and inefficient, bureaucratic and unsympathetic methods of rule tended to prevail. Since World War II, however, major changes have occurred; 1954 saw the enactment of a comprehensive labour law which sanctioned and encouraged co-operation movements, extended provision for educational and cultural improvements, and laid down minimum wage rates for workers. Trades unions came into existence unofficially about 1924 and became legal in 1944; some have since been dissolved by governmental action and others infiltrated by Communist sympathizers. The law of social security (1956) formulated a plan of national insurance, covering old age, illness, death and unemployment; but its provisions need time to become fully operative.

4. Justice.—At the start of mandatory rule, the existing Ottoman civil and commercial law codes were retained, and the penal code replaced; after 1945 both the civil and commercial laws were in turn altered. There are now three types of court: civil, religious and special; and in addition tribesmen are permitted to accept tribal justice. Trial by jury does not operate in Iraq. The civil courts are organized by *liwa'* into courts of first instance and appeal courts; personal status (marriage, divorce, inheritance, etc.) is dealt with by religious community courts; and the special courts deal with tribal land cases, political offenses, malpractices by officials, and the interpretation of the constitution and its legal implications. *Ad hoc* military courts are set up in the *liwa's* if deemed necessary.

5. Education.—Education developed considerably after 1920. Primary schools, then less than 100, now number about 2,000; and elementary education is in theory free and compulsory, though in fact only a minority of Iraqi children attend school regularly. Female education has progressed with the opening of mixed primary schools, but the over-all proportion of pupils is 4:1 in favour of boys. Most colleges of higher education are now co-educational, and technical institutes have been started since 1947. To co-ordinate the working of the various existing colleges of higher education the University of Baghdad was inaugurated in 1956. There has been much enthusiasm for development, leading to marked advance; but the abstract, didactic and theoretical nature of Iraqi teaching tends on occasion to obscure logical and critical thinking. Preoccupation with politics and a fear of overproduction of graduates have also been adverse factors. Many Iraqi students are sent abroad to study, mainly in the U.S., U.K. and Lebanon.

6. Defense.—At its creation, the Iraqi state was faced with both internal turbulence and the hostility of its neighbours; the British government moreover was disinclined to maintain a large British force within Iraq. Hence the creation of a strong Iraqi army (and also later an air force) was one of the earliest developments, and the army has remained a pillar of the state—the symbol of independence and power, closely influencing events, and in turn having the personal interest and support of the ruler. Compulsory national service was introduced in 1935, and the air force came into being in 1930. Training and equipment for defense were first provided by Britain, with some U.S. participation from 1954; and later Soviet assistance was obtained. The former R.A.F. base at Habbaniyah was evacuated in May 1959.

V. THE ECONOMY

Iraq is still overwhelmingly an agricultural country. Despite the richness and wide extent of petroleum deposits, the number of Iraqis actually employed by the oil companies is relatively small; and although oil revenues play a highly important part in development, they provide a much smaller percentage of the gross national product than agriculture and stock rearing. Manufacturing, very restricted before 1950, has increased significantly but is still on a small scale. More than 75% of Iraqis still live by agriculture or stock rearing, either directly or by handling the products.

1. Agriculture.—The 15-in. isohyet dividing Iraq into two climatic provinces (rain-watered agriculture and irrigated cultivation) also coincides approximately with the northern limit of the date palm, hence the country really comprises two agricultural regions. In one, the smaller, which takes in Assyria and Kurdistan, barley, wheat and Mediterranean crops (fruit, tobacco, nuts) are staples; in the other, where irrigation is essential, barley, dates and rice are the chief crops. Barley is the main cereal of Iraq, because of its tolerance of aridity and a saline soil, and also because, having a relatively short growing season, it is less likely to be affected by pests, the most widespread of which are the sunn pest, a small insect which appears in late summer and bores into the ear, and the locust, which arrives in swarms usually from Arabia. Yields of barley can be double those of wheat; native strains are not especially productive, but improvements have followed the introduction of foreign varieties. The principal areas of barley growing are the lower Tigris valley round Kut and the Shatt al Gharraf, the middle Euphrates zone from Nasiriyah to Samawah, and the Assyrian plains, especially round Mosul, Irbil and Kirkuk. Rice is grown extensively only in low-lying areas where irrigation is easily available. Under good conditions it produces over four times as much as barley or wheat per unit area planted, and it is thus the main cereal crop of lower Iraq. Specially good areas are the marshes round 'Amarah (Tigris) and two zones on the Euphrates, the Shamiyah area between Najaf and Diwaniyah, and from Nasiriyah as far as the head of Lake Hammar. Rice is also grown in small plots in the mountain valleys of Kurdistan, where it is much more a delicacy. Because of heavy demands on irrigation water the total area devoted annually to rice growing is restricted by law, but since World War II marked expansion has occurred, parallel with the enlargement of irrigation works. Wheat, like barley, is grown as a winter crop and more than 70% of Iraqi production is still from Assyria, where it is grown with or as an alternative to barley. Some production also occurs on the upper Tigris and Euphrates valleys. Two cereals of recent introduction are millet and maize (corn), both of which are summer crops and therefore useful as an element in rotation. Millet is used as an adulterant in human food and as animal fodder, while maize is still a new introduction.

Iraq produces most of the world's export supply of dates. The palms can tolerate extremely dry and sandy conditions, but bear best with a copious supply of water. A hot, long and bright summer is also essential; hence conditions along the lower valley of Iraq are ideal, and the southern Tigris and Euphrates, especially the Shatt al Arab round Basra, are the most productive areas.

The ground is dug over annually, and the female palms artificially pollinated in April. Harvesting begins in August, and many nomads arrive in the region as temporary labour. The finest quality fruit is produced only in moderate quantities; but more prolific palms carry up to 120 lb. of dates annually, of lower quality. Dates form an important, sometimes principal, article of diet (they keep well, provide sugar and do not easily carry human disease), and the stones of the date are used as animal fodder. *Arak* (a spirit) is distilled.

Cotton is grown in increasing quantities, though soil salinity is one distinct handicap, another being liability to attack by weevils and locusts. Quality is not outstandingly high, and levels of production have oscillated, reflecting world conditions, because until the 1950s there was little or no home demand. Now east Asia (Japan and Hong Kong) and Europe provide markets, with exports exceeding £1,000,000 annually, while a newly established home industry has further stabilized the position. Other crops are tobacco and vines, both for internal use only and largely within the hill country of the northeast. Nut trees are important in a few localities; and market gardening around the larger cities is increasingly important, reflecting rising standards of living and the new demand from such groups as oil-field workers. Experiments have been made with flax, jute, alfalfa, sesame, peanuts, potatoes, yams and clover. There is much individual variety in fruit and vegetable growing, especially in the rain-watered zone, though yields are sometimes less than in irrigated areas.

A number of wild crops are also important. Licorice grows along the banks of the principal rivers as far south as the Shatt al Arab, and the root is dried for export for tobacco curing and as a sweetmeat. Gum tragacanth is an exudation from a bush which occurs in drier steppe regions, and about one-half of world production, used in sauces and pharmaceuticals, comes from Iraq. The valonia oak, native to the higher, damper mountains of the north and east, produces an extract used in tanning.

2. Irrigation.—The problems involved are somewhat complex because of the time of flooding, at the season when many crops are partially grown. Excess water must be retained within the river between high banks. Variation in the level of the river beds means that in some parts free-flow irrigation is possible, while in others pumping is necessary. Stagnant water must be led back to the rivers as rapidly as possible, again by pumping if necessary, in order to avoid salination.

The largest river control project is that of the Wadi ath Tharthar, completed in 1956. A canal 40 mi. long leads from the Tigris at Samarra' to the basin of the wadi, which thus accumulates floodwater. The basin was expected to fill by 1966, but because of possible seepage and contamination by salt deposits it was not known whether the water would be usable for irrigation; there were, however, definite possibilities of generating electricity. A smaller project on the Euphrates employs similar methods; water is led off from the mainstream at Ramadi into two basins, at Habbaniyah and Hawr Abu Dibs. The Habbaniyah basin is definitely saline, so only flood control can be achieved. Other regulator dams are complete or under construction: on the Little Zab at Dokan —a high dam of 350 ft., with extensions at Batma, 'Udhaim and Kirkuk; on the Great Zab at Bekhme; and on the Tigris above Mosul. These are primarily for irrigation, with flood control and electricity generation as subsidiary features.

The earliest modern irrigation work was at Hindiyah (1913, enlarged 1922) which directs the Euphrates water into an older channel running through Hillah; and also on the Euphrates are the Musayyib project (1956) and smaller works at the head of Lake Hammar. At Kut on the Tigris a barrage completed in 1943 and three times the size of the Hindiyah dam will ultimately improve irrigation south and southeast of Kut; but a limiting factor there is the restricted volume of water available in summer. The entire low-season flow of the Diyala river below the Jabal Hamrin is now diverted for irrigation. Other irrigation works on a smaller scale are planned or in construction around Lake Hammar, the Shatt al Arab, Sulaymaniyah, Irbil and Mosul. Between £30,000,000 and £40,000,000 has also been spent on land drainage projects (to counter salination) and on windbreaks to prevent the silting up of irrigation and drainage channels. In all, more than £100,000,000 had been devoted to irrigation and flood control by the early 1960s, and it was planned to spend as much again.

3. Livestock.—This is proportionately much more significant than in many other countries of the middle east. Because of the extent of mountain, desert and even unirrigable stretches within the riverine lowlands, the boundary between cultivated and grazing land is far less sharp than, say, in Egypt; and alternation of the two kinds of terrain encourages herding in close proximity to cultivation. Within the steppe and mountain zones (Al Jazirah and much of Kurdistan) stock rearing is by far the most important activity; in occasional years exports of animal products can be as valuable as those from agriculture.

Sheep number 7,000,000–8,000,000 and are chiefly found in Al Jazirah, and the arid zones south and west of the Euphrates; but south Assyria and the Gharraf areas are also important. There are four breeds: the Arabi, chiefly found in the lowlands; the Karadi (Kurdish), larger and fatter but with coarser wool; the Tartar (fat tailed) and the best meat producer; and the Awassi, a cross between the first two. There is usually a well-developed seasonal migration of sheep. During winter and spring they move into the arid areas, where a flush of grass occurs until about May–June; in summer they are brought back into the riverine lands where they are kept either near marshy tracts or on fallow cultivated ground where their manure is valuable. In Kurdistan transhumance is practised.

Goats (2,000,000–3,000,000) occur mainly in the hillier parts of the north and east, and in the drier areas. They furnish milk, meat and hair valuable for tent cloth and for Arab clothes which, when well made, are waterproof. Cattle are kept, mainly in riverine areas, for milk (meat is rarely eaten) and as draft animals for plowing and the operation of irrigation wheels. Camels are still bred in considerable numbers in the deserts; formerly their main use was for transport, but increasingly they are slaughtered for their meat and hides. Camels do not thrive in the swampy lowlands; there water buffalo are numerous, and about 80% of the total in Iraq are found in the four southern *liwa's*. Donkeys are the principal beasts of burden, and mule breeding is important in Kurdistan. As elsewhere in the middle east a few horses are kept, but definitely as an exotic luxury.

There has long been a trade in animals with neighbouring countries. Formerly they were driven westward to market in the Levant using a circuitous route along or close to the Euphrates. But with the advent of through railway connection, and above all, the motor truck, live animals are increasingly transported for sale in Syria, Lebanon and Jordan. Wool is exported to Europe mainly for use in carpets; it is of lower quality than Australian wool.

4. Forestry.—In 1955 a forest law was passed. Forest land had been greatly reduced by cutting for fuel and the grazing of animals, and only 2,800 sq.mi. of woodland, much of marginal quality, could be said to exist in Iraq. There had hitherto been little concern for woodland, but various 20- and 50-year plans were then drawn up, with the aims of doubling present forest areas, and of creating tree avenues on certain main roads. The poplar is well established in parts of the northeast, and in drier sandier areas eucalyptus was introduced with some success. A forest police was started, and extension of woodland was given importance as a protection against soil erosion and the silting of irrigation canals, and for the provision of building timber, practically all of which must now be imported.

5. Oil.—Overwhelmingly the most important mineral resource in Iraq is petroleum, which is now exploited in the northeast, north and south of the country. The first field to be developed was at Kirkuk (1927), which lies on a lowland embayment between the Zagros and the Mesopotamian plain. In this area there is a fold structure, the Pusht-i-Kuh, running parallel to the main Zagros, which dies out to northwest and southeast, where two enclaves of lower ground occur, one in Iran which forms the Masjed Soleyman oil field, and the other in Iraq, at Kirkuk. The geological structure is interesting. At Kirkuk the petroleum is held in Eocene-Miocene limestone about 1,000–2,000 ft. thick, termed Main limestone. Above lies an impermeable complex of Miocene shales, salt and

W. B. FISHER AND E. W. PULLIN

PRINCIPAL TOWNS, OIL FIELDS, PIPELINES AND RAILROADS OF IRAQ

anhydrite which acts as a seal, and the whole series is folded into long anticlines and synclines striking northwest-southeast. A special feature is the continuity of porous rock series into the main Zagros farther east; hence considerable hydrostatic pressure within the rock is induced from rainfall at higher levels, producing in the oil region itself pressures of 2,000–3,000 lb. per square inch—a fortunate circumstance in that there is no need to pump the oil, which rises of itself in immense gushes. At Kirkuk there is an oil-bearing anticline 50–60 mi. long (a huge size for such structures, which are normally measured in yards) and only 38 wells are needed to tap the entire structure (*cf.* 25,000–30,000 wells in Texas). A much smaller field in the southern embayment (at Naft Khaneh, just inside Iraq) produces oil which is refined at Alwand near Khanaqin, and serves only the internal needs of Iraq, with no export. Deposits of petroleum also occur within the riverine lowlands (the bitumen at Hit has been exploited for 2,000–3,000 yr.), and oil fields have been developed at 'Ayn Zalah and Butmah (north of Mosul), and at Zubayr-Rumaylah near Basra. First discovered in 1939 but not productive until 1952, the Mosul field has a relatively small reserve of lower grade oil, held in Cretaceous limestone. The Zubayr field has been developed since 1949 and now ranks second to Kirkuk. Its reservoir rock is of Cretaceous sandstone, like that of adjacent Kuwait, at greater depth and only slightly folded into a very shallow anticline. Other petroleum deposits are known to exist in central Iraq, but these are "heavy" and sulfurous, and under present conditions are uneconomic to exploit.

Because of distance involved (about 4,000 mi. by sea from the mouth of the Shatt al Arab to the eastern Mediterranean) and Suez canal dues, it is normally cheaper to move oil from Kirkuk by pipeline, whereas oil from the Basra area is shipped by tanker. Two 12-in. pipelines were constructed from Kirkuk to the Mediterranean, running together as far as the crossing of the Euphrates at Al Hadithah. The lines then divided, one continuing via Palmyra, Syria, to Tripoli, Lebanon, the other via Ar Rutbah to Haifa, Israel. This latter was closed by the Iraqi government during the Israel-Arab war of 1947–48. It had been planned to construct a 16-in. pipeline to Tripoli and Haifa, and the Tripoli branch came into operation in 1949; the other remained unfinished. A 30–32-in. pipe was completed to Baniyas, Syria (about 40 mi. N. of Tripoli), in 1952, giving a transportation capacity of 14,000,000 tons annually. Because of the vulnerability of pipelines to political and other pressures, it is policy to diversify routes—hence the alternative terminal in Syria; and the possibility of a new pipeline via Turkey has been considered.

The entire oil production of Iraq (with the exception of the Khanaqin field formerly owned by the British Petroleum Oil company but after 1958 operated by the Iraqi government) is controlled by the Iraq Petroleum company (I.P.C.) and its two subsidiaries, the Basrah Petroleum and Mosul Petroleum companies. This group began before World War I as an Anglo-German group, known as the Turkish Petroleum company, but was reconstituted after 1918 and renamed, the shareholders being: B.P.O.C. 23¾%, Royal Dutch Shell 23¾%, Near East Development company (Standard Oil of New Jersey and Standard Vacuum of New York) 23¾%, Compagnie Française des Pétroles 23¾%, and the foundation of Calouste Sarkis Gulbenkian (*q.v.*), the original negotiator of the concession, 5%. The British government is a majority shareholder in the B.P.O.C., and the French government owns 35% of the rights in C.F.P. Under an oil agreement of 1952, Iraq receives 50% of the profits before deduction of foreign taxes and, as from Jan. 1956, the companies guaranteed a minimum annual output of 30,000,000 tons. In Dec. 1961 the Iraqi government announced that the combined concessions of I.P.C. and its associates, which had previously covered almost the whole country, would be restricted to an area of less than 750 sq.mi. (although allocation of additional areas could be authorized).

Other Mineral Resources.—These comprise (1) a deposit of brown coal at Kifri between Baghdad and Kirkuk, a few thousand tons of which are produced annually; (2) small-scale local deposits of potassium nitrate, gypsum and quartz; (3) rock salt

TABLE II.—*Oil Fields of Iraq*

Field	Date of development	No. of wells	Annual production (1962; bbl.)	Cumulative production to 1962 (000,000 bbl.)
Naft Khaneh	1923	2	1,095,000*	59†
Kirkuk	1927	38	258,900,115	2,503
'Ayn Zalah	1939	4	7,691,760	73
Zubayr	1949	23	24,978,604	317
Butmah	1952	4	1,951,580	18
Bai Hassan	1953	6	16,705,522	42
Rumaylah	1953	14	40,451,338	337
Jambur	1954	4	6,108,656	20

*1959 figure. †1960 figure.

which is exploited in a number of localities under government supervision as subject to taxation. Small deposits of copper, iron, chromium and manganese are known to exist, but there is no large-scale exploitation.

6. Industries.—These are on a small scale. Prior to 1940, there were little more than craft industries producing textiles, building materials (chiefly cement), food products and leather goods, together with a restricted amount of modern machinery. Since about 1940 attention has been given to industrial development, with some state participation in oil refining, asphalt, cement, and tobacco and food processing. Textile production (mainly cotton and rayon with some jute) is the most important activity, with a number of modern factories in Baghdad, Mosul and Basra.

Development.—Much economic improvement achieved in Iraq has been financed by the state, through a development board established in 1950. Some 75% of oil revenues received by the Iraqi state (these averaged about £75,000,000 annually in the late 1950s–early 1960s) are allocated to the board, together with further sums from taxation. Various economic development plans (5-, 6-, or 7-year) have been initiated, some for the improvement of communications (*e.g.*, better road surfacing and the conversion of metre-gauge railways to standard), some to education and some to flood control and irrigation.

7. Trade and Finance.—Domestic trading is of two kinds. Westernized department stores serve an exclusive small group of well-to-do people. However, most Iraqis use the traditional bazaars, retail trade being especially brisk in the holy cities. Peddlers and traveling merchants visit villages and tribal camps.

Foreign trade is dominated by petroleum, which by value accounts for about 85%–90% of all exports, and is at an annual level of about £100,000,000 ($280,000,000). Most oil moves untreated to Europe, with small but increasing amounts to eastern Asia and Africa. Other exports are mainly of agricultural and pastoral products, especially grain and flour (barley and wheat) to neighbouring areas (particularly Arabia, Jordan and Lebanon), with some export to the U.K. for malting purposes. Iraq is the largest world exporter of dates (about 80% of world sales); and there is a significant export of raw cotton, chiefly to Japan, Hong Kong, India and eastern Europe. Wool and hides are sold to Europe, and there is some trade in live animals with Jordan, Lebanon and Turkey. Production of oil continues to grow fairly steadily; but in contrast, exports of other products (dates excepted) tend to experience sharp annual fluctuations, reflecting the vagaries of climate within Iraq and changing world prices.

Capital goods (steelwork, machinery and vehicles) are the principal imports, followed by foodstuffs (sugar, tea, etc.) and textiles. By the early 1960s annual exports (excluding oil) averaged about £16,000,000, transit traffic (to Turkey, Iran and Arabia) £8,500,000, and imports £120,000,000, the balance being covered by petroleum exports and by subventions or loans from abroad chiefly for the armed forces. Main trade links have been with the U.K. (which takes about half of total oil exports and supplies 30% of imports), the Federal Republic of Germany and Japan. Some increase in trade with the U.S.S.R. was suggested after the fall of the monarchy, but, at least at first, was more putative than actual.

The unit of currency is the Iraqi dinar. I.D. 1 = £1 sterling; I.D. 1 = U.S. $2.80. The greatest single item in the revenue of the state is the oil royalties, about 40%–45% of the total. The remainder of the revenue is raised by taxes both direct and indirect. There are several foreign banks operating in Iraq and four government banks.

8. Communications.—Originally the rivers provided most of Iraq's means of communication, but they are greatly declining in importance. The railway system (now operated by the Iraqi State Railways administration) gradually developed: of standard gauge from Baghdad to Mosul and (in 1940) connecting Syria and Turkey; and of metre gauge from Basra to Baghdad, and on to Kirkuk. This was an inconvenient system, and plans were made to extend the standard-gauge line to Basra and the metre-gauge line from Kirkuk via Irbil to Mosul, and to change over to diesel haulage.

Flooding restricted road development for a long time. In 1950 there were only 1,500 mi. of surfaced roads, the rest being of earth and impassable in winter. By the early 1960s more than 4,500 mi. of roads and tracks had been developed for motor traffic, which increased greatly. Air-conditioned buses operate to Damascus and most of the pilgrim traffic from Iran is handled by motor coach. There are international airports at Baghdad and Basra, and a state-owned airline operates within Iraq and abroad, with pilgrim flights to Jidda. Air, rail and to some extent road services are integrated by a state board. Radio and television stations in Baghdad are a government monopoly administered by the ministry of guidance.

IRBID, the third largest and the most northerly city of the Hashemite Kingdom of Jordan, lies on the northwest corner of a rich corn-growing plain, 40 mi. N. of Amman. Pop. (1961) 44,805. The houses are built of white limestone and black basalt, and part of the town covers a mound which represents the Early Bronze Age town of about 2500 B.C. A section of the ancient basalt town wall can be seen on the west. The town is an administrative and commercial centre linked by main road with Amman, Syria, and the desert road to Iraq. (G. W. L. H.)

IRBIL, also known as Arbil, Erbil or Arbela, an important foothill town in northeast Iraq, about 48 mi. E.S.E. of Mosul in 36° 15′ N. and 44° W.; pop. (1957) 34,751, largely Kurds. The long unbroken history of Irbil, attested by the accumulation of building debris which forms the high citadel mound, is explained by its position as a centre of communications and by the fertility of the countryside, which is for the most part adequately watered and produces good cereal crops. It is the commercial and administrative centre for the *liwa'* (province) of the same name, bounded west by the Tigris, north and south by the Great and Little Zab rivers, and east by the Iranian frontier.

The city was known to the Sumerians in the 3rd millennium B.C. as Urbillum, and later, as Arba'ilu, ranked among the principal cities of Assyria; it housed a famous shrine of Ishtar (*q.v.*), and Sennacherib (*q.v.*) dug a canal, partly underground, to supply it with water from the Great Zab. In Achaemenid times it lay on the royal road through Nineveh from Sardis to Susa and Alexander the Great defeated the last Achaemenid, Darius III, on this road about 31 mi. W. of Irbil (*see* Gaugamela, Battle of). Under the Parthians, Arbela became the capital of the petty kingdom of Adiabene, approximately the modern *liwa'* of Irbil; the city apparently retained its religious importance, since many Parthian kings were buried there. In the late Abbasid period it was a considerable town and a fine minaret of this era still stands in the plain below the deserted citadel, whose western side is skirted by the older part of the town; more modern buildings now extend across the plain. A tarmac road from Mosul to Kirkuk and Baghdad passes through Irbil, whence there is a branch through the Rawanduz gorge to the Iranian frontier. A metre-gauge railway runs from Irbil through Kirkuk to Baghdad.

(E. E. D. M. O.)

IRELAND, JOHN (JOHANNES DE IRLANDIA) (*c.* 1435–*c.* 1500), Scottish writer, theologian and diplomatist, whose treatise *The Meroure of Wyssdome* is the earliest extant example of original Scots prose, was educated at the University of St. Andrews. He left without taking a degree, and attended the University of Paris, of which he was made a licentiate in 1460. He lived in France till 1483–84, becoming a doctor of theology and being sent on several diplomatic missions by Louis XI. On the death of Louis he returned to Scotland and became private chaplain to James III. He was rector of Yarrow and sat in the Scottish parliament. When James died in 1488 he continued as chaplain to the young James IV, and wrote for his edification, in 1490, the work which is his chief claim to fame, *The Meroure of Wyssdome*, a hortatory and pious treatise on the value of wisdom to temporal rulers.

(E. G. M.)

IRELAND, JOHN (1838–1918), U.S. Roman Catholic archbishop, a leader of the "progressive" clergy, was born at Burnchurch, County Kilkenny, Ire., on Sept. 11, 1838. In 1849 he was taken to the United States by his parents, who settled at St. Paul, Minnesota territory. After being educated in France for the priesthood, he was ordained at St. Paul in 1861. In the following year he accompanied the 5th Minnesota Volunteer Infantry south as chaplain. Subsequently he became rector of the cathedral at St. Paul.

At the request of Bishop Thomas Langdon Grace of St. Paul Ireland was appointed bishop-coadjutor with the right of succession in 1875. Nine years later he became bishop of the diocese, which was raised to metropolitan rank in 1888.

Ireland's liberal views gave him a wide influence and reputation both within and without the church, and he came to be looked upon as a leader of the "progressive" as distinguished from the "conservative" party in the clergy, principally in the Americanism, Cahenslyism and school controversies. By Europeans he was looked upon as the Catholic intellectual leader in the U.S. His ideas on social reform and the relation of the church to a democratic society were in advance of his time. He was prominently identified with the planting of Catholic colonies in the northwest, with the establishment of the Catholic university at Washington, and with the Catholic total abstinence movement. He published *The Church and Modern Society* (1896). Archbishop Ireland died at St. Paul on Sept. 25, 1918.

See James H. Moynihan, *The Life of Archbishop John Ireland* (1953).
(P. H. A.)

IRELAND, JOHN NICHOLSON (1879–1962), English composer known for his evocative works of literary and pictorial associations, was born at Bowdon, Cheshire, on Aug. 13, 1879. He entered the Royal College of Music, London, in 1893 where he studied with Sir Charles Stanford. Later he taught composition there; his pupils included E. J. Moeran and Benjamin Britten. His first important work was the song cycle *Songs of a Wayfarer* (1903–05). His piano pieces *Decorations*, including "The Island Spell" written at Jersey in 1912, are prefaced by quotations from the writings of Arthur Machen, the novelist and essayist, to whose fantasy and mysticism he was greatly drawn. *The Forgotten Rite* (1913), for orchestra, was similarly inspired by Machen. His symphonic rhapsody *Mai-Dun* (1920–21) evokes a vision of the prehistoric earthwork, Maiden Castle, in Dorset.

Ireland spent much time in the Channel Islands, where he wrote the piano suite *Sarnia* (1940–41). He also wrote a piano concerto, many picturesque or evocative piano works, among them the *London Pieces*, and songs on poems of Thomas Hardy, A. E. Housman, Arthur Symons and others. He died at Washington, Sussex, on June 12, 1962.

See N. Townshend, "The Achievement of John Ireland," *Music and Letters* (April 1943).
(E. LR.)

IRELAND, WILLIAM HENRY (1777–1835), Shakespearean forger whose faked manuscripts deceived many of the leading scholars of his day, was born in London, the son of Samuel Ireland, a dealer in rare books and prints. As a boy, he was much impressed by the career of Thomas Chatterton (*q.v.*). He was articled to a conveyancer in chancery at New Inn and so became familiar with ancient documents and handwriting. On a visit to Stratford in 1794 he encountered John Jordan, a wheelwright and amateur poet with a fund of Shakespearean anecdotes of doubtful authenticity. Jordan's romances and the elder Ireland's passionate desire to acquire Shakespearean relics probably inspired William to produce his forgeries, which he pretended to have obtained from a rich gentleman who preferred to remain anonymous. Later, he improved upon this story, claiming that one of his own ancestors had saved Shakespeare from drowning and had been rewarded by the poet with the gift of his manuscripts. These included Shakespeare's "Profession of Faith"; stanzas to Anne Hathaway; and a letter to Shakespeare from Queen Elizabeth I. In Feb. 1795 the elder Ireland held an exhibition of the precious documents at his home, and it was there, on Feb. 20, that James Boswell knelt and kissed the supposed relics. Ireland did not, however, enjoy universal confidence; some newspapers denounced his forgeries from the first.

The ludicrous failure of his "Shakespearean tragedy" *Vortigern* at Drury Lane theatre on April 2, 1796, and the publication of Edmond Malone's *An Inquiry into the authenticity of certain papers . . . attributed to Shakespeare* (1796) discredited him. He admitted his forgery in *An authentic account of the Shakespearian manuscripts* (1796), following this by his more detailed *Confessions* in 1805. His father died in 1800, probably broken by the shock of the whole affair. It seems likely that he was the victim of his son's duplicity. After some years of precarious existence Ireland succeeded in obtaining fairly regular employment from London publishers. He died in London on April 17, 1835. He never showed any shame at his conduct, and his effrontery is well illustrated by the title page to a collection of his forgeries: "The following pages contain the several Autographs &c produced by me, W^m H^y Ireland, during my fabrication of the Manuscripts which I wrote & attributed to William Shakespeare" (British museum manuscript Stowe 994, f. 1). The museum also possesses the elder Ireland's correspondence relating to the forgeries and numerous specimens of Ireland's work.

See G. H. Libbis, "Notes on Ireland," in *Notes and Queries*, vol. clx, pp. 201–204, 219–221 (1931), vol. clxii, pp. 236–239, 347–350 (1932).
(GD. B.)

IRELAND, an island of distinctive character to the west of Great Britain, is bounded on the northeast by the North channel, on the east and southeast by the Irish sea and St. George's channel, and on the west and south by the Atlantic ocean. Its greatest length north-northeast to south-southwest from Fair head (Antrim) to Brow head (Cork) is 306 mi. and from east to west 182 mi. Brow head is the most southerly point on the mainland, though there are islands farther south, and the most northerly point is Malin head (Donegal). The most easterly point is on the coast of the Ards peninsula (Down) and the most westerly Dunmore head in the Dingle peninsula (Kerry). Ireland averages 110 mi. in breadth and 220 mi. in length; its area is 32,595 sq.mi. The minimum distance from Great Britain is 13½ mi. between the Mull of Kintyre (Scotland) and Torr head. The narrowest crossings of St. George's channel are about 50 mi. in the south and 70 mi. in the north: from Holyhead to Dublin the distance is 65 mi. Ireland's history has been concerned with immigrations of settlers and would-be conquerors though it is now known as a land supplying many emigrants. It is part of the Atlantic fringe of Europe, and has been called "the last outpost of Eurasia." Many of its physical features bear an obvious resemblance to those of Great Britain, yet it is best regarded as a separate land, possessing a landscape molded by a different physical and human history. Since 1921, it has been divided into two political units, Northern Ireland (area 5,459 sq.mi.; pop. [1961] 1,425,462) and the Republic of Ireland (area 27,136 sq.mi.; pop. [1961] 2,814,703). There are separate articles on IRELAND, NORTHERN and IRELAND, REPUBLIC OF.

This article concerns subjects common to both countries and contains the following sections:

I. Physical Geography
1. Geology and Relief
2. Drainage
3. Coasts
4. Climate
5. Vegetation
6. Animal Life
II. Geographical Regions
III. The People
1. Racial Types
2. Language
3. Religion
4. Customs and Culture
IV. Archaeology
V. History (to 1921)

I. PHYSICAL GEOGRAPHY

1. Geology and Relief.—Conspicuous features of the physical landscape are the similar trend or alignment of many hills and valleys, and the extensive peneplains or erosion surfaces of fairly uniform altitude, about 2,000 ft., 800 ft. and 200 ft., with others, such as those at 600 ft. and 400 ft., which are less well marked. A third major characteristic is the prevalence of drifts due to the effects of the Quaternary glaciation of the country. Both the erosive and depositional work of ice have had considerable influence on the detailed physical features.

The older, often severely folded strata generally emerge at the surface in mountain areas round the margin of the land mass, with younger strata in the central lowland. The rim of rocks representing the main axis of folding in early Paleozoic (*i.e.*, Caledonian) times is seen in the northwest in County Donegal and in the north in the Sperrins on the borders of Tyrone and Londonderry where the mountains are composed of early Paleozoic and older strata folded along these axes. The west-east or Armorican trend is dominant in the southwestern peninsulas of Kerry and County Cork, where the strata include the Old Red (Devonian) Sandstones and Carboniferous shales and limestones. The mountains of the Dingle peninsula (Kerry) comprise the Brandon range, with Brandon mountain (3,115 ft.), and the Slieve Mish range, with Baurtregaum (2,796 ft.). The Macgillycuddy Reeks have Ireland's highest mountain, Carrantuohill (3,414 ft.). Inland from these peninsulas there are long west-east valleys extending into Counties Cork and Waterford, floored by Carboniferous rocks, between which anticlinal interfluves of Devonian sandstones rise as ranges, *e.g.*, Boggeraghs, Knockmealdowns and Galtees (Galtymore 3,018 ft.). An isolated peak (2,510 ft.) in County Mayo is the quartzite Croagh Patrick (*q.v.*).

In the central lowland a change occurs: rocks of Devonian and Carboniferous age are gently folded in a southwest-northeast trend, possibly because older mountain ranges, of Caledonian age, underlay the newer rocks when they were folded, *e.g.*, the Slieve Bloom and many ranges to the south of a line from Galway bay to Dublin. South of Dublin the Leinster chain extends for more than 70 mi. to County Waterford in a northeast-southwest direction. A vast anticlinal arch due to the intrusion of granite during the Caledonian mountain building, it is a fine upland as much as 10 mi. wide in places, with Lugnaquilla (3,039 ft.) in County Wicklow as its highest summit. Farther north, in County Down, the Mourne mountains were formed by a granite intrusion in Tertiary times; the highest point is Slieve Donard (2,796 ft.). The extreme northeast has Tertiary basaltic intrusions which form plateaus in County Antrim 1,000–1,500 ft. high, but floor the Bann valley.

Preglacial erosion surfaces have been widely recognized at various altitudes in Great Britain, reflecting a comparable history of erosion and uplift, and it might be expected that a similar pattern should occur in the adjacent land mass of Ireland. The recognition of such surfaces in Ireland is, however, difficult, for in many places they are covered by glacial deposits of varying thickness, *e.g.*, 50–100 ft.; and these in turn are frequently covered with postglacial peat bog of varying depth. In the south glacial deposits are generally thin or nonexistent, and vast stretches of the 200-ft. surface are visible, notably topping cliffs along the coast. There also appears to be an extensive surface at about 200 ft. in the central lowland, which is by no means the flat, featureless plain it is sometimes imagined to be. From Dublin roads and railways climb westward on to the 200-ft. level, but above this there appears to be a rise to an altitude of 400 ft. as, for example, in County Meath where there are large areas at this altitude, and it also occurs in some of the wide lowland corridors between the various uplands, such as that between Portlaoise (Maryborough) and Thurles. The 800-ft. surface is clearly marked in the lower parts of the west-east ridges of the south and also in many uplands, for example in County Donegal, where the peaks rise above it to 2,000 ft. or more. Another major erosion surface may exist at 600 ft., but it is possible that this is the higher ground from the 400-ft. surface, or lower ground from the surface at 800 ft.; these altitudes are not absolute, but rather are indicators of the general level of erosion surfaces which may be horizontal, but in other cases sloping. For example, in the Calary district of the Wicklow mountains there is thought to be an expanse of the 800-ft. surface, but in fact it slopes from 1,000 to 600 ft. Finally, the 2,000-ft. surface which exists on Slieve League, County Donegal, is thought to be of Devonian age, as on it there are Carboniferous beds. The other surfaces were probably cut during the Tertiary period: possibly the uplift of the land between them was associated with the Tertiary orogenic movements.

2. Drainage.—Rivers and lakes are an attractive element in the Irish landscape. Of these the greatest is the Shannon (*q.v.*), 161 mi. long, which with its various tributaries, such as the Suck and the Inny, drains one-fifth of the area of Ireland. Almost entirely a river of the lowland, it spreads into numerous lakes (loughs), such as Allen, Bofin, Ree and Derg. Most of the other rivers

reaching the west coast are short though the Erne, flowing to Donegal bay, is 64 mi. long and loses its identity in the two Erne loughs. In County Galway, Loughs Mask and Corrib are joined by underground channels through the porous Carboniferous limestones. The short Laune river is the outlet for the famous lakes of Killarney (*q.v.*) to Dingle bay. To the south of Killarney all the rivers are swift-flowing mountain streams for the greater part, in some cases almost the whole, of their courses.

The pronounced west-east line of the mountains and valleys in the extreme south is reflected in the courses of the rivers. Of these the Bandon flows for 45 mi. to reach the sea at Kinsale (Cork). The Lee, rising only a few miles from the Atlantic coast, flows for over 55 mi. to Cork harbour, which it enters after dividing into two arms round the city centre. The Blackwater, 104½ mi. long, rises in the Carboniferous plateau country of Kerry and northwest Cork and flows into the sea at Youghal (Cork).

In Waterford harbour the three rivers, the Suir, Nore and Barrow, known as the "three sisters," meet. The Suir, 114 mi. long, rises in the Devil's Bit mountain. The Nore rises close to the Suir, but in its 87-mi. course runs southeast across the lowland to New Ross, County Wexford, where it is joined by the Barrow. This river rises in a peat bog of the central lowland and, like the Nore and the Suir, gradually finds its way into an entrenched valley course which it occupies until its junction with the Suir.

Rivers of the Leinster chain are mainly short swift-flowing streams, but two are of special interest. The Slaney, 73 mi. long, rises on the slopes of Lugnaquilla and enters the sea in Wexford harbour. No other river cuts through the Leinster chain. The Liffey rises 12 mi. from the sea but turns west to the edge of the central lowland and bends east through the city and its outskirts to Dublin bay. In the central lowland, north of Dublin, the Boyne rises in the Bog of Allen and flows for 70 mi. to the estuary near Drogheda (Louth): it is joined by its main tributary, the Blackwater, at Navan (Meath). Like many other Irish rivers, the Boyne occupies a gorgelike valley cut in the general lowland surface at 200–400 ft.

Belfast is divided into two by the Lagan, a short canalized river now known chiefly for the shipyards beside its dredged channel. In the northeast the glens of Antrim have short swift streams. The most famed of the northern rivers is the Bann, normally divided into two parts; the upper Bann rises in the Mourne mountains and flows to Lough Neagh, 25 mi. away, in a course that begins as a mountain stream but soon settles in a flood plain, and the lower Bann covers 33 mi. largely through peat bogs, to the sea. Lough Neagh (*see* NEAGH, LOUGH), 52 ft. above sea level, receives on its northern shore the river Main which flows parallel to the Bann, but in the opposite direction.

Lough Foyle is the outlet of the Foyle river, north of Londonderry; strictly the name Foyle applies to the 16 mi. of river from Lifford to the lough, but the whole drainage basin includes several streams draining the Sperrin mountains, as well as the Strule, the Derg and the Finn. Beyond the Foyle basin, in County Donegal, there are numerous short rivers, many of which run parallel to the mountain chains, there possessing a marked northeast-southwest Caledonian trend.

Glaciation.—This has been a major factor in the development of the Irish landscape, through the actions of ice and of meltwater, both in erosion and in deposition. The country was affected by two main glaciations, of which the earlier, or Eastern General, covered most of the country except for the southwest. The newer, or Midland General, extended as far south as a terminal moraine along a line forming the Shannon estuary to a point near Cahir, across the lowland to the western side of the Wicklow mountains, and spread into valleys on the north and east of this range and out to sea a few miles north of Wexford. Contemporaneously there was a separate ice sheet over Cork and Kerry, and various mountain glaciations, as in the Wicklows, where there are some fine glaciated valleys, such as Glendalough (*see* GLENDALOUGH, VALE OF). Various areas were ice-free, including the summits of the Macgillycuddy Reeks in Kerry, though these uplands had a corrie glaciation which has left strikingly sculptured forms. On the east coast an ice stream from Scotland and the Irish sea penetrated inland and southward for some distance.

The passage of ice removed much of the soil, particularly from areas in the west, and elsewhere left thick deposits, especially in the east. The removal of soil was severe in areas such as Connemara, where large expanses of bare rock are covered only by postglacial peat bogs and the mountains are almost bare of vegetation. Numerous erratic boulders were transported and later deposited by the ice, and as they can be traced by the rock type to the area of origin, the direction of ice movement is known. Equally striking are the extensive areas of bare limestone (karsts) in County Clare (the Burren), in the Aran Islands and in a belt of country to the north and south of Galway bay. By contrast, in the east there are places where glacial deposits are as much as 100 ft. thick, while in the Curragh (*q.v.*) the sands are 234 ft. thick. To a great extent the agricultural possibilities depend on the nature of the glacial deposits: well-drained ground and terminal moraines generally develop good soils under the damp Irish climate, but the one-time fens between them have become peat bogs. Long sinuous ridges, known as eskers, which may be due to deposition of sand and gravel by ice meltwater streams, are common in the lowland and generally have poor grassland or are wooded, while some have been quarried for sand and gravel. Interesting glacial features are the drumlins of which there are several thousand in the northern part of the lowland, *e.g.*, in and around Clew bay (Mayo), in the Erne valley and south Donegal, in a wide belt extending from County Sligo almost to Dundalk (Louth) and also in County Down and the Bann valley. These elongated whale-backed mounds have their steeper end facing the source of the ice which deposited them and so their alignment indicates the various directions of ice movement during glacial periods. These drumlins, said to cover one-eighth of the surface of Ireland, vary from a few hundred yards to a mile in length and are more than half as broad. In Cavan and Monaghan, and in south Donegal, these mounds dominate the scene, with lakes and bogs in the dips between them: in County Down they are small and in places so rounded that the countryside has been said to have a "basket of eggs" topography. Offshore, in Clew bay on the west and in Strangford lough on the east, the drumlins appear as a multitude of islands.

Ice meltwater, during various phases of the glacial period, carved channels and was impounded in lakes held up by ice. This is seen round the Wicklow mountains, where the ice front lay parallel to the mountain edge, and in consequence the meltwater, running in the same direction, cut overflow channels at right angles to the present drainage system. There are said to be at least 120 of these, including some over 100 ft. deep: some of them drained extensive meltwater lakes in which large deltas were deposited. Ice melting (at several periods) released large volumes of water, and many valleys now occupied by small streams were carved by these meltwater torrents. It appears that in this area the present river system is successor to a great meltwater system of drainage. In the lowland particularly, glacial erosion and deposition left large areas of indeterminate drainage with vast areas of fen in hollows between morainic and other land forms of glacial origin. During the drier early postglacial period these fens were better drained and had forests including oak, alder and willow, but during the succeeding wetter, cooler climatic periods, continuing to the present time, acid peat has accumulated on a large scale. Many of the smaller bogs have long since been cut away for fuel; since the beginning of World War II several large raised bogs have been exploited for domestic fuel or to supply power stations (*see* IRELAND, REPUBLIC OF: *The Economy*). In the west, bog has accumulated as a blanket extending over hills and slopes as well as hollows, but once this is cleared no soil remains: the area of bare rock in the west has been greatly extended by the cutting of this blanket bog. Blanket bog occurs where the annual rainfall exceeds about 40 in. and the air is frequently, if not invariably, damp.

3. Coasts.—The coasts of Ireland are as varied as the land behind them: many of the coastal waters are dangerous, hard to navigate and subject to heavy gales. The main harbours are all in river estuaries: the Norse invaders established Dublin on the

Liffey, Wexford on the Slaney, Waterford on the Suir, Cork on the Lee and Limerick on the Shannon. Belfast, on the Lagan, is of later date but owes its present deep channel and importance to dredging and river control; so does Londonderry on the Foyle. Along the northeast coast, the Antrim coast road runs along a raised beach (due to postglacial recovery of the land after glaciation and the rise in sea level during that period). In the extreme northeastern corner of Antrim there are spectacular cliffs composed of basalts and dolerites. Near Bushmills (Antrim) basalts form the Giant's causeway (*q.v.*), a fine exposure of hexagonal basalts with a coast walk in which a splendid series of basaltic rock forms may be seen. Lough Foyle has on the east extensive sand dunes and reclaimed land, and on the west the rocky coast line of Donegal. The Donegal coast is varied: there are some spectacular cliffs, such as those nearly 600 ft. high on Horn head, and the land is penetrated by the long inlets of Lough Swilly, Mulroy bay and Sheep haven. The west coast of Donegal has stretches of sand dunes alternating with cliffs; the finest feature is the quartzite scarp falling nearly 2,000 ft. into the sea from Slieve League. Off the coast there are numerous islands. Round Donegal bay there is a lowland formed of Carboniferous limestones covered with numerous drumlins but the main beauty lies in the back cloth of hills beyond the lowland.

From Sligo bay westward the coast is interrupted only by the inlet of Killala bay (Mayo) and has some fine cliffs. The west Connaught coast is marked by the Mullet, most of it a line of sand dunes protecting an agricultural area, and Achill (*q.v.*) Island, with quartzite scarps similar to that of Slieve League in Donegal. At the head of Clew bay there are scores of islands formed of drumlins, and here the scenic glory lies in the surrounding mountains. Between Clew bay and Galway bay there is an intricate coast with a large number of islands, and on the north shore of Galway the land merges gently into the sea, without cliffs. Galway bay has the three islands of Aran across its entrance (*see* ARAN ISLANDS), and on the south the flat coast of Clare where, near Black Head, there is a vast limestone pavement swept by the sea. But the most famous feature of west Clare is the 600-ft. vertical cliffs of Moher, in Carboniferous flagstones, and many lesser cliffs along the coast.

South of the flat shores of the Shannon estuary, Kerry has some fine cliffs, notably at Brandon head in the Dingle peninsula. Much of the long ramifying coasts of the southwest consists of an alternation of sandy bays and cliffed coasts. The south coasts are too varied for detailed treatment, but in general they consist of cliffs up to 200 ft. high, interrupted by inlets such as those forming the harbours of Kinsale, Cork, Youghal and Waterford, with some sheltered sandy bays at places along the coast. In the southeast Wexford harbour is the largest inlet, and the coast includes some long stretches of sand dunes and pebble ridges guarding marshes, with many miles of cliffs, some of which show glacial drifts over the rock beds. Here, as on the south coast, there are extensive sandy beaches and sheltered coves.

4. Climate.—Commonly described as "mild, moist and changeable," Ireland's weather shows an almost imperceptible temperature gradation from one season to another with rain a common element throughout the year, particularly in the west. Along the Atlantic coasts, where the mean monthly temperature for December to March is 7° C. (44° F.), there is little seasonal check to plant growth. This is especially so in such sheltered valleys as those round Killarney, where a rich evergreen vegetation includes laurels, rhododendrons, the Mediterranean arbutus, and holly, with oak and other deciduous trees. In the east winter temperatures are slightly lower, about 5° C. (42° F.), but sheltered gardens in Dublin may have an abundance of blooms even in December and January.

The rainfall over four-fifths of the country averages 30–50 in. per year, with much higher totals on mountains and in exposed places near the Atlantic. A particular hazard of the climate is the distribution of rain through the year; in many years heavy rains during the harvest period, especially in September, cause difficulties. The number of rain days averages 175 a year in the east, but reaches 250 in the wettest parts of the west.

The incidence of sunshine is relatively low, June being the sunniest month. Leinster, which is the sunniest region, has a daily average of seven hours sunshine during June (the maximum period); this decreases to two hours during December (the minimum period).

Winds are predominantly westerly and at times heavy gales can do considerable damage to shipping, particularly on the west coast. Equally, damage is done to standing crops by high winds, especially when combined with heavy rains. Though the frost incidence is lower than in Great Britain, occasional frosts in late April or even early May damage fruit and other crops, including early potatoes. Normally, early potato crops are successful, and in some years highly remunerative in parts of the west, including the Aran Islands. (T. W. Fr.)

5. Vegetation.—The Irish flora is essentially an impoverished version of the British flora: impoverished partly because Ireland is a smaller and less diversified island than Britain, and partly because it was isolated earlier than Britain in postglacial times. Some 15 species of higher plants are found in Ireland but not in Britain; these are mostly extreme Atlantic species which probably survived the last glaciation in western Ireland when they were exterminated elsewhere in northern Europe.

The natural woodlands of Ireland have been almost completely destroyed. The limestone plain, which was probably occupied originally by oak-ash-alder wood, is now converted to pasture and meadow. On siliceous rocks in the hills some fragments of the original oak-birch-holly-rowan wood remain, but most of the area it covered is now heathy moorland or rough pasture. This deforestation began in Neolithic times and was completed in the 17th century; modern reafforestation uses mainly exotic species of conifers. In the limestone Burren of County Clare alpine species such as gentians and mountain avens (*Dryas octopetala*) have spread in the absence of a shrub vegetation.

The more exposed mountain slopes and the western seaboard are too windswept to support trees. The present mountain vegetation of heaths, with crowberry, dwarf juniper, etc., is fairly natural, as is also that of the large bogs of the west and centre, where the deep peat is covered by bog cotton and other sedges, grasses such as *Molinia*, dwarfed heather and *Sphagnum* moss.

The equable temperature and high humidity, especially in the west, promotes rapid growth if shelter from the wind is provided, so that in sheltered situations an impression of subtropical luxuriance often prevails. This applies especially to ferns and mosses, which are much more abundant and luxuriant than in Britain. Round Killarney, for example, are woods of oak, arbutus, birch, holly and rowan with a rich ground flora of saxifrages, ferns, mosses and liverworts. (X.)

6. Animal Life.—This is very similar to that of Britain but contains fewer species in almost every group. The following larger animals are absent as breeding species: woodpeckers, voles, the common shrew, the mole and the greater horseshoe bat. Reptiles and amphibia are represented solely by the lizard *Lacerta vivipara*, smooth newt, natterjack toad and common frog. The last named, together with aliens like the brown rat, house mouse, house cricket and a number of other insects, has probably been introduced. The poverty of the number of species as compared with Britain is probably due to the severance of the land connection between them before the break of the land connection between England and France following the retreat of the ice in the postglacial period. A number of animals have a wider distribution in Ireland than in Britain (*e.g.*, Leisler's bat). As with the flora there is a small Mediterranean element in the fauna (*e.g.*, the Kerry slug, *Geomaculus maculosus*) and an American element (*e.g.*, the freshwater sponge *Heteromeyenia ryderi*), together with a number of arctic relicts. The isolation of the fauna has resulted in a number of differences between similar animals in Britain and Ireland. This is seen in the Irish breeds of the hare, stoat, jay and red grouse. (J. N. R. G.)

II. GEOGRAPHICAL REGIONS

The Northwest.—This area comprises Donegal, the Foyle valley and the uplands and lowlands of Sligo. Donegal's agriculture is restricted to lowlands and mountain valleys, and becomes richer

in the east toward the Foyle valley. Sligo has plateaus, deep valleys and coastal lowlands. Rainfall is high (40–70 in.) except in the north; the winters are mild (5° C. [41° F.] Dec.–Feb.) and summers cool (14.5° C. [58° F.]). The high rainfall and mild temperatures encourage a luxuriant plant growth though winds frequently limit tree growth on the coasts. Bogs are common where the drainage is poor. Oats, potatoes, grass farming, sheep and cattle form the basis of the economy; some of the agriculture is carried on as cottage farming.

Connaught and Clare to the Shannon Estuary.—This area has a similar climate to the northwest but is slightly warmer and wetter (rainfall averages between 40 and 60 in. with up to 100 in. in the mountains). Average temperatures are 6° C. (43° F.) in winter and 15° C. (59° F.) in summer. Tree growth is limited along the coastal strip by the strong winds which have also forced agriculture and settlement to sheltered places or have compelled farmers to build high walls round their fields. Agriculture is mainly pastoral with sheep predominating on the dry limestones and cattle on the better grasslands; sheep supply wool for Donegal and Irish tweeds. On the farms and cottage holdings potatoes and oats are the main crops.

The Southwest.—High rainfall (60–100 in.) and a relatively warm climate mark this region. Rainfall is not uniform and decreases to 50 in. in the lowlands. There is a pronounced winter rainfall maximum; rain falls on an average of three out of four days. Vegetation is luxuriant, verging to subtropical. There are extensive boglands in areas of excessively poor drainage and rich woodlands in sheltered, well-drained places. The soils are derived from Old Red Sandstone, limestone and superficial deposits. Agriculture is pastoral with the cultivation of oats and potatoes and some dairying, stock rearing and hog farming. Sheep are less numerous than in other areas.

The South and Southeast.—This region, extending northward to the Slieve Bloom, is marked by a rainfall of 30–40 in. in the lowlands, increasing to over 40 in. in Cork and Waterford. The winters are mild, 7° C. (44° F.), the summers comparatively warm, 15° C. (59° F.) July average. This area also has the highest sunshine average in Ireland. The lack of blanket bog has made extensive cultivation possible and on some farms one-third of the land is arable. The main crops grown are oats, barley, turnips, potatoes, beets and some wheat. Pasture for dairy herds and store cattle is excellent and farming is prosperous. Sheep are also grazed extensively.

The Central Lowland.—This is characterized by a much drier climate, receiving 30 in. or less rain per year. Temperatures vary according to exposure; in some areas winters are very mild. Agriculture is mainly pastoral as the soils are heavy, impermeable boulder clays and limestone drifts. These give rise to very rich grasslands, but crops can only be grown where the land is well drained. There are some famous stud farms in this area. Cattle are reared for beef and for dairying. The plain includes the major bogland area in Ireland and is the site of several peat-fired electricity stations. There are also hydroelectric projects; *e.g.*, Pollaphouca on the western edge of the Wicklow mountains in the Liffey valley.

The Northeast.—This is one of the most intensively farmed areas in Ireland. The climate is cooler than in other parts (4.5° C. [40° F.] winter mean) but becomes warmer along the coasts. The summer mean is 15° C. (59° F.). Rainfall varies from 30 to 60 in. according to location. Agriculture is dominated by grassland, both for pasture and for seed raising. Other crops are oats, potatoes and a little wheat and barley. The traditional flax growing had almost ceased by the early 1960s. Livestock includes pigs, sheep, cattle (store and dairy) and poultry. (T. W. Fr.)

III. THE PEOPLE

1. Racial Types.—The most distinctive anthropological feature of the Irish people is the combination of light eyes and dark hair. In samples taken from all Irish counties 40% were found to have blue eyes and a further 44% blue-brown. Hair colour is normally dark brown, but black hair is rare and declines to less than 1% in some areas: the highest proportion of dark hair is found in Waterford and Wexford. A broad belt of relatively light hair runs down the island from Londonderry to Cork, extending westward into Galway, and in this belt red hair reaches its maximum (7.5%) in Leitrim and Cavan. The mean stature of adult males is high (172 cm.; 5 ft. 8 in.): it is lowest on the east coast and highest in Kerry and Galway. The span-stature index is remarkably high. Heaviest mean body weight occurs in the west, especially in the westernmost peninsulas. Heads everywhere tend to be mesocephalic, the index ranging by counties from just below 78 in Meath and neighbouring counties to a little over 80 in Kerry.

Many attempts have been made to correlate these anthropometric variations with prehistoric and historic invaders. C. S. Coon discerns strong Upper Paleolithic elements in the populations of Kerry and Cork and claims that at least half of the genetic ancestry of the composite modern Irishman is to be referred to the survival of strains from the first Mesolithic inhabitants of the island. E. A. Hooton disputes this but thinks that Nordic-Mediterranean features—long headed, tall, dark haired types with mixed pigmentation—are basic and represent a prehistoric substratum. While there is little agreement as to origins most workers recognize at least six subracial types and all are agreed that post-Celtic settlers have had little effect on the composition of the population, though they strengthened certain pre-existing subracial types. It is paradoxical that the so-called Celtic type (of medium stature, long-headed, combining blue eyes with darkish hair) is most concentrated along the east coast, while the physical characters of the population group which has most successfully retained the Gaelic language—the Aran islanders—have been plausibly attributed to a strong admixture of blood from English garrisons in Cromwellian and later times.

2. Language.—The Gaelic language, once universally spoken but now generally replaced by English, is a member of the Goidelic branch of the Celtic tongues. Areas which preserve Gaelic as the language of the home are now few and scattered, being virtually confined to the westernmost peninsulas of Donegal, north Mayo, south Galway and Kerry. The official Gaeltacht (Gaelic speaking) areas of the republic are somewhat more extensive, since they include adjacent areas where the language has not entirely died out. It is the avowed policy of the republic to revive the use of Irish as a vernacular language in these adjacent areas, but it may perhaps be doubted whether this will be any more successful than the attempts which have been made, mainly through compulsory teaching in the schools, to restore the Irish language as the habitual medium of speech throughout the republic. (*See* also Celtic Languages; Irish Literature.)

3. Religion.—Religion enters deeply into the fabric of life in both parts of the island, and the churches exert a strong influence in social and educational affairs. Taking the island as a whole, the proportions of Roman Catholics (75%) and Protestants (25%) have remained fairly stable since the middle of the 19th century, despite heavy emigration and other demographic changes. Since political partition, in 1921, the greater part of the Protestants have been contained in Northern Ireland, where Roman Catholics and the two main protestant groups, Presbyterians and Church of Ireland adherents, are almost equally represented in the total population. Roman Catholics, however, are the largest single denomination in Northern Ireland, and whereas they are found in all parts of the province there are many districts in the republic where there are no Protestants. In fact only about 6% of the people of the republic are Protestant, mainly belonging to the Church of Ireland, and this percentage is declining steadily. The strongest Protestant communities are found in Dublin, Wicklow, Cork and the three Ulster counties of Donegal, Cavan and Monaghan. The political division of Ireland is not considered in the ecclesiastical organization. The Catholic primate of all-Ireland and the primate of the Church of Ireland have their seats at Armagh in Northern Ireland and the headquarters of the Presbyterians and Methodists are in Belfast.

4. Customs and Culture.—Many parts of rural Ireland, and especially the Gaeltacht, have preserved a strong tradition of oral literature from which the Irish Folklore commission has built up an extensive archive. Folk tales, fairy lore and calendar customs

are also richly represented in the collections, the quarter days marking the beginning of February, May, August and November (All Hallows) being especially important in the folk calendar. In the field of material culture, rural Ireland is no less rich in ethnographic survivals, which include the wheelless slide cars of Antrim, the hide currachs of the river Boyne, the seagoing currachs of the west coast, the rawhide shoes of the Aran Islands and the one-eared spade which is commonly used throughout the south of the island. In folk art Ireland has little to offer, decorative painting for instance being almost unknown. A wide range of skilled techniques in wood, metal and illuminated manuscripts is attested in early historic times, but the humble artifacts of the peasant, though often of great ethnographic interest, are for the most part strictly utilitarian. This material poverty contrasts strikingly with the vigorous development of nonmaterial forms of expression, in conversation, poetry, song and dancing. Country games which are found locally include skittles, handball and bowls ("hullet-throwing"). Other ball games which enjoy a wider popularity are hurley and Gaelic football. Attracting large crowds in the county championship games, they may be regarded as the national forms of competitive sport. As for rugby football and most games the island is not partitioned when international teams are selected.

(E. E. E.)

IV. ARCHAEOLOGY

The Mesolithic Age.—The human occupation of Ireland does not begin until a late date in the prehistory of Europe. The island seems to have been uninhabited throughout the whole of the Ice Age; at least no incontrovertible trace of an interglacial colonization had been found by the early 1960s. The earliest relics of man appear in the remains of a culture of Mesolithic affinities, evidence for which has been found at Cushendun, Larne, Rough Island and other places on the northeast coast of the country and also at other coastal sites in Counties Louth and Dublin. This culture has been divided into two phases, called Early and Late Larnian after the type site at Larne (Antrim). As the majority of the sites associated with the culture are secondary and as most of them are on beaches, the relics they have yielded consist entirely of implements of stone and flint. Early Larnian is characterized by microliths, scrapers and blades allied to those of the Mesolithic cultures of the adjacent areas of Britain. Its descent is probably to be traced to the British Upper Paleolithic and it may be roughly dated to 6000 B.C. Late Larnian is regarded as a local evolution of this culture and its equipment of flint tools tends to be of a more massive type. The people of both these phases were dependent for subsistence chiefly on hunting and fishing, supplemented by minor food collecting activities. It would seem that groups of these people survived in lakeside and riverside settlements until the coming of the Neolithic agriculturalists and pastoralists.

The Neolithic Age.—Radiocarbon datings suggest that the Neolithic culture was well established in the country before 2500 B.C. The surviving artifacts of the period are polished stone axes, leaf-shaped arrowheads, hollow scrapers and pottery vessels belonging to the general type of western Neolithic. The pots are simple round-bottomed bowls, plain or decorated; round-bottomed shouldered bowls, which may be either plain or ornamented; and a flat-bottomed ware of coarse texture. Habitation sites have been excavated at Lough Gur (Limerick) where houses, both round and rectangular in plan, were discovered. The economy of the inhabitants seems to have been based largely on cattle rearing and only to a minor extent on agriculture. The burials of the period include both single graves and collective tombs. The single graves generally consist of a stone cist, sometimes covered with a circular mound of earth. The collective tombs are the earliest of the Irish series of megalithic monuments and, from one of their most characteristic features, have been called court cairns. A typical tomb of this type has an open court giving access to one or more galleries, each containing two or more chambers, roofed with lintels and divided from each other by pairs of jamb stones which have, occasionally, a sill stone between them below. The court is bounded by orthostats and varies from a full circle to a segment of one. The whole tomb, excluding the court, was covered with a low cairn, more or less trapezoidal in plan. In distribution, these tombs are confined to coastal and upland districts in the northern half of the country, a pattern which has been

PATRICK. (BOTTOM, LEFT TO RIGHT) TARA BROOCH, 8TH CENTURY A.D.; GOLD GORGET, LATE BRONZE AGE; BRONZE CAULDRON, LATE BRONZE AGE; GOLD COLLAR, 1ST CENTURY B.C.

interpreted as reflecting a settlement of incoming people arriving by sea on the western coast and gradually spreading eastward over the better drained and less heavily forested land. Cremation was the normal burial rite in these tombs and the scanty grave goods are in the full Neolithic tradition. The dispersal focus of these people is unknown and the ultimate derivation of their characteristic tomb undecided.

The Bronze Age.—The early Bronze Age, which seems to have begun some centuries before 2000 B.C., was a continuation of forces already at work in the preceding period, strengthened by fresh ones which made their appearance about that time. Of the latter, one of the most important was the Beaker culture. The Lough Gur site, already mentioned in connection with the Neolithic, produced considerable quantities of the very distinctive Beaker pottery and further finds of it have been made in megalithic graves in Derry (Londonderry), Tyrone, Sligo and Dublin. The beakers found are of mixed British and continental affinities and their presence presumably indicates an immigration of people. It is worth noting, however, that no burials of the kind typical of the British beaker tradition have been found.

A factor which may have contributed to the flourishing state of early Bronze Age culture in Ireland was the presence of gold. The metal is still to be found, although not in commercially remunerative quantities, in the gravels of mountain streams in County Wicklow. As no traces of ancient mining have been discovered, it is probable that the supply was won from the same alluvial gravels in early times. The large number of gold ornaments of the early Bronze Age which have been found in the country prove that considerable amounts of the metal were available. Among the earliest types of these gold objects are the lunulae: crescents of thin gold sheet, having the tips of the horns enlarged and bent at right angles to the plane of the crescent. An average specimen is about 8 in. in diameter. They are decorated with finely engraved geometric patterns, the ornament being restricted to the horns, except for a narrow band bordering the outer and inner edges of the wider portion of the crescent. A few have been found abroad but the great preponderance of those of Irish provenance points to an origin in Ireland. Another early gold object is a small disc of sheet metal bearing a cruciform design ringed by ornamental bands. They have generally been found in matching pairs and, since each is provided with two small holes in the centre, it is thought that they were originally attached to some backing material. From a later phase of the Bronze Age there are numerous torques made of gold bars and ribbons spirally twisted. They vary greatly in size, from specimens small enough to have been used as bracelets to ones large enough to have been worn as girdles. A characteristic ornament of the late Bronze Age consists of a thin round gold bar bent into a semicircle with a funnel-shaped expansion at each end. To the same period belong eight magnificent gold gorgets, all discovered in the region of the Shannon estuary. They are decorated with bold moldings enriched with *repoussé* work and attached to each of their terminals is a disk bearing a pattern formed of groups of concentric circles. Whatever the significance of their very limited distribution, these gorgets have definite north European affinities.

The weapons of the earlier phase of the Bronze Age included flat axes and small triangular daggers, and rapiers which appeared at a somewhat later stage. The axheads frequently bear geometrical decoration executed by punching and hammering. Some of the daggers were hafted by means of a tang, but more usually the handle was secured to the blade by rivets. The rapiers are long slender blades strengthened by a midrib and the halberds are broad, daggerlike blades which were mounted by means of rivets at right angles to one end of a long handle. As the Bronze Age advanced the flat ax was superseded by the palstave, an ax with a relatively narrow blade and a pocket on each side to accommodate the ends of a split knee-shaped handle, to which the head was further secured by lashing through a loop cast on the edge. Cast bronze spearheads of beautiful proportions were produced in a great variety of sizes by the native smiths. In the later part of the Bronze Age new types of weapons, based on imported models, replaced the long established patterns. The axhead was cast hollow to provide a socket for the end of the handle and the looped spearhead was replaced by one which was attached to the shaft by pegs or rivets passing through holes in the socket. An entirely new kind of weapon, a slashing sword with a leaf-shaped blade, appeared and to this phase of the period also belong the earliest shields discovered in the country. These are circular, with a central hemispherical boss surrounded by concentric moldings and were made of bronze, leather or wood. The art of the bronzesmith was not limited to the production of weapons alone for the existence of hammers, saws, chisels and gouges shows that he provided the tools for other craftsmen as well, although the only agricultural implement which he was called upon to supply was the sickle. The large cauldrons which he made for domestic use rank among the finest specimens of his workmanship. Their swelling contours are built up of comparatively small sheets of bronze fastened together with close rows of decorative conical-headed rivets and the stout everted rims are provided with two large ring handles by which the vessels could be suspended over the fire. He also cast the first musical instruments in the country of which there is any present knowledge, trumpets, both side- and end-blow, which imitate in shape and size the cattle horns which were their exemplars.

The megalithic tombs, which began with the court cairns of the Neolithic period, continued to be built in the Bronze Age but new types, representing several waves of cultural influence from abroad, made their appearance. Of these, the passage graves, although not the most numerous, comprise some of the most impressive monuments in the country. Roughly speaking, they extend across the central third of the country and are commonly grouped in cemeteries on hilltops or high ground. The most important of these concentrations are those beside the river Boyne and on the Loughcrew hills in County Meath and at Carrowkeel in County Sligo. The largest of all the tombs is the enormous tumulus of Newgrange on the Boyne. It covers an acre of ground and encloses a great cruciform chamber built of corbeled slabs of stone, many of which are decorated with spirals, chevrons and lozenges pecked into their surface. The chamber is approached by a linteled passage of massive stones and the whole mound, which is about 40 ft. high, is girdled round the base by a continuous curb of huge stones laid end to end. The mound was originally encircled by a ring of large standing stones, most of which have been destroyed. The Boyne group includes two other great tumuli which approach Newgrange in dimensions: that of Dowth containing two independent chambers, the stones of which bear decoration similar to that found in Newgrange, while the other mound, known as Knowth, has its curb profusely ornamented with a wide variety of patterns of this peculiar art. Further examples of it occur in the Loughcrew cairns, at Knockmany and Sess Kilgreen, both in County Tyrone, and in a tomb at Fourknocks, County Meath. Some of the patterns appear to be very schematized anthropomorphic motifs. The scanty grave furniture of those passage graves which have been excavated includes round-bottomed highly decorated pots of a kind known as Carrowkeel ware, small stone pendants shaped like hammers and mushroom-headed bone pins.

The wedge-shaped gallery grave, characteristic of the southern third of the country, has walls constructed of upright slabs which support a roof of horizontal capstones and, as the name indicates, the tombs are wider at one end than the other. They are frequently two-chambered, with a large compartment at the wider end and a smaller one behind it at the narrower end. While the grave goods of some show Neolithic survivals, the more common occurrence of beaker pottery and tanged-and-barbed arrowheads demonstrates that they are to be assigned to the earlier part of the Bronze Age.

A further kind of megalithic tomb is the portal dolmen. This is a single-chambered structure, usually narrowing toward one end, the entrance being flanked by two tall portal stones and the whole covered by a single capstone, often of enormous size, which slopes down from the tall portals to the rear of the tomb. They are found in the north and extend southward along the east coast but are rare elsewhere and seem to be wholly absent from the southwest.

Burial was, however, by no means confined to the megalithic tombs for one of the commonest Bronze Age graves is a stone cist of rectangular plan, constructed of four slabs set on edge and covered by a capstone, the entire structure being sunk in the ground. The body was either cremated or inhumed and a highly decorated pot, known as a food vessel, often accompanied by a slug-shaped flint blade, was usually deposited with the remains. Food vessels fall into two broad types, bowl- and vase-shaped, the former being the commoner. In late Bronze Age times a new kind of funerary pottery appears: a large wide-mouthed urn, tapering to a flat base. One type of urn is decorated with cordons and rudely executed incised geometrical ornament, the other with strips of clay applied to the surface to produce an encrusted effect. The urn may be enclosed in a protecting stone cist or merely buried in the ground and it is often found in an inverted position over the cremated bones.

The Iron Age.—There is no clear cut line of distinction between the end of the Bronze Age and the beginning of the Iron Age although the latter may be said to have begun about 500 B.C. and to have ended about A.D. 500. The Hallstatt or earlier phase of the continental Iron Age is represented in Ireland only by a few discrete cultural elements such as a small group of bronze swords and sword mounts and several bronze buckets or situlae. From the succeeding La Tène period the finds are more numerous and more culturally coherent. They include personal ornaments in gold, silver and bronze decorated in the style typical of the period; items of horse furniture, such as beautifully designed bronze bridle bits; long curved trumpets of riveted sheet bronze; iron swords, spearheads and tools; and a few carved standing stones, including those at Turoe (Galway) and Castlestrange (Roscommon). It is to this period that the immigration which introduced the Celtic speech must be assigned. The oldest written relics of this Celtic language are enshrined in the Ogham inscriptions, most of which appear to date from the end of the Iron Age (*see* OGHAM WRITING). Ogham stones are particularly abundant in the extreme south of the country and some are to be found in Wales and Scotland. In later centuries some of these pagan memorials were "christianized" by the addition of a cross, usually of the equal-armed type enclosed in a circle. Although the articles of actual Roman origin found in the country are relatively few in number, there is an increasing body of evidence to suggest that there was very considerable contact between Ireland and the Roman and romanized world during the latest phase of this period.

The Early Christian Period.—While there can be little doubt that small Christian communities existed in the country prior to the middle of the 5th century, it was not until the arrival of St. Patrick (*q.v.*) about that time that large scale conversion from paganism began and that the church became an integral part of the social structure. Christianity brought with it Latin learning and cursive writing and created the need for books, church buildings and their furnishings. The earlier Christian centuries were characterized by the development of an ascetic monasticism, leading to the foundation of numerous small monasteries which were frequently situated in islands off the coast or in then uninhabited tracts inland. One of the most inaccessible of these settlements was on the towering rock of Skellig Michael off the Kerry coast where the early stone-built beehive cells still exist in a remarkable state of preservation. A number of these monasteries developed into schools of learning of considerable size and importance, among them being Clonmacnoise in County Offaly and Clonard in County Meath. Many of the sites retained their importance down to the 12th century and were, in the time of the Viking incursions, provided with tall round towers which functioned as places of refuge, belfries and lookout points. About 100 of these towers remain in varying states of preservation. A typical example is about 90 ft. high, with a doorway at a considerable height from the ground and four windows immediately below the conical roof. Internally, it was originally divided by wooden floors into stories, each lit by a small window and communicating with the next by a ladder.

Also associated with monasteries and other ecclesiastical sites is a series of large carved stone crosses, ranging in date from the 8th to the 12th century. They vary greatly in size but an average specimen may be from 10 to 15 ft. high. It is set on a pyramidal base and at the junction of the arms and shaft the members are connected by four arcs which give a wheellike appearance to the head of the cross. The earliest of the group are to be found in the southeast of the country and two particularly fine examples are situated at Ahenny, County Tipperary. Such figure sculpture as they bear is confined to the base, the cross proper being entirely covered with ornament of which interlacing forms the staple. In origin, these earliest crosses seem to be gigantic enlargements in stone of metal prototypes. Various lines of development from this early type can be traced, the broad result of which was to lend increasing prominence to figure sculpture until a stage was reached when the cross was formally divided into a large number of panels, each illustrating an incident from the Old or New Testament, such purely decorative carving as was still retained being similarly apportioned into separate compartments. Perhaps the best example of this stage of evolution is the excellently preserved cross of Muiredach at Monasterboice, County Louth, which dates to the early 10th century. The iconographical plan on these later crosses shows a marked influence from contemporary continental religious art.

Evidence for other aspects of the artistic achievement of the period survives chiefly in metalwork and manuscript illumination. A large body of metalwork, both lay and ecclesiastical in origin, reveals the adaptation by Irish craftsmen of many techniques from Britain and the European continent. An instinct for design added to the superlatively skilful use of these techniques enabled them to produce many objects of outstanding craftsmanship. The Tara brooch, which dates to about the middle of the 8th century, may be taken as an example of these beautiful objects which have been found. It, like its fellows, consists of a long straight pin with a triangular top looped to a ring terminating in two large expansions, the outer edges of which complete the circumference of the circle of the head. The front of the head is divided into panels embellished with geometric and zoomorphic interlacing in filigree and set with studs of amber, and blue and red enamel. The back of the brooch is decorated in a different and older style with spirals, trumpet patterns and animal interlacements. The top of the pin is also elaborately ornamented and the lower end terminates in a stylized animal head. An even more remarkable 8th-century object is the large silver ministral chalice found at Ardagh, County Limerick. It is a wide two-handled cup with a stem and a broad circular base and measures seven inches in height and nine and one-half inches in diameter. Below the bronze rim is a band of small panels of gold filigree interlacements separated by studs of blue and red enamel. The handles are divided into panels in which gold filigree and glass mosaic plaques alternate, while their escutcheons are set with enamel bosses overlaid with a silver network. The stem, the upper and lower surfaces of the flange around the base and even the underside of the base itself all bear enrichments in a great variety of techniques and designs.

Among the other metalwork from the 9th to the 12th centuries are mounts of various kinds, pins, brooches, bells and numerous shrines and reliquaries for articles associated with the native saints. These last include elaborately decorated containers for bells, books, staffs and bodily relics. One of the latest of the series is the great processional cross from Cong, County Mayo, which was made about 1125 to enshrine a relic of the True Cross.

The style of the later pieces is influenced by Scandinavian art with which the country had been brought into contact by the Viking incursions. These began toward the end of the 8th century as raids on coastal settlements and monasteries but in the course of the succeeding century the intruders established themselves in a number of strategic places around the coast, the main centres being at Dublin, Wexford, Waterford, Cork and Limerick. Apart from such of the larger monastic centres as might have partaken of an urban character, the pattern of settlement in Ireland had hitherto been a completely rural one and these Scandinavian outposts formed the nuclei of the first towns in the history of the country.

Manuscript illumination parallels and complements the metalwork in early Christian art. The growth of the church called for

the multiplication of books for instruction, study and divine service and these were produced in the scriptoria of the monasteries. The benefits of letters were not, of course, restricted to purely religious texts and the native traditional literature in prose, saga and verse was also committed to writing, together with a large corpus of legal tracts and much else of a miscellaneous character, to produce the largest body of early vernacular literature in western Europe. Most of the manuscripts containing material in the Irish language are comparatively late, the oldest being no earlier than the 12th century, but, because of the existence of secular schools of learning with strong antiquarian propensities, they contain much matter which was already linguistically archaic when incorporated in the manuscripts. As might be expected, few of these manuscripts are decorated and the art of illumination is bestowed chiefly on texts destined for church use and ritual. The most famous of the Irish illuminated manuscripts is the *Book of Kells*, a copy of the four Gospels which can only have been made in one of two Columban foundations, Iona or Kells. It probably dates to the end of the 8th century. The earliest surviving illuminated manuscript is the *Book of Durrow*, dating to the second half of the 7th century. Irish missionary activity on the continent led to the dispersal there of books illuminated in Ireland or to the production in Irish continental foundations of books illuminated in the Irish style. In all these manuscripts the illumination is in great part confined to initial letters and is executed mainly in ribbon and zoomorphic interlacements of astonishing intricacy and wealth of invention. Representations of human beings are largely limited to figures of the four evangelists and even these are treated in an abstract and stylized manner (*see* also ILLUMINATED MANUSCRIPTS: *Ireland*).

There can be little doubt that the greater number of the buildings of the time, both secular and ecclesiastical, were made of wood, timber being readily available from the great oak forests which still covered large areas in most regions of the country. Building in stone was, however, practised for special reasons or in those places where timber was scarce. The defensive round towers mentioned above are an example of stone buildings erected for special purposes, and the beehive cells of Skellig Michael are an example of the resort to stone where wood was unobtainable. Dry-built beehive cells, most of them now ruinous, survive on early monastic sites along the west coast from Inishmurray, County Sligo to the Dingle peninsula, County Kerry. They are constructed of courses of flattish stones, each course slightly oversailing that below so that the diameter of the cell constantly diminishes as it rises until the final opening left is small enough to be closed with a single large stone. A more developed, but less stable, type of dry-built construction is to be seen in a small rectangular oratory, numerous in Kerry, in which the side walls are skilfully corbeled inward until they meet in a ridge above the centre line of the floor. The end walls have a slight inward batter and in one is a doorway with sloping jambs and in the other a small round-headed window. The only example standing intact is that known as the Gallarus Oratory, situated near the tip of the Dingle peninsula. When mortared stone churches began to be built, probably in the 9th century, this type of roof was in some cases retained and examples of it are to be found in churches at Killaloe (County Clare), Kells (County Meath) and Glendalough (County Wicklow). One of the last and certainly the most ambitious of these stone roofs is that of the 12th-century Cormac's chapel in Cashel, County Tipperary. The majority of the early mortared churches were, however, roofed in the orthodox fashion with rafters carrying thatch or shingles. Many of these structures show, in such details as gable barges and gable finials, the translation into stone of features proper to wooden buildings. The romanesque style was introduced sometime in the 11th century and appears to have been in fashion for about a hundred years, during which there were built a considerable number of churches, most of them, like their predecessors, of relatively small size, and in which some of the characteristics of the earlier buildings, like sloping door jambs, persisted. In these romanesque buildings decoration is concentrated chiefly on the doorways, of which the finest example is that at Clonfert, County Galway, and on the chancel arches, of which the most elaborate is that at Tuam in the same county.

If, in dealing with the early Christian period, attention has been concentrated on aspects of art and architecture which are principally ecclesiastical in context, it must not be thought that archaeology has nothing to tell about the life of the ordinary people of the time.

There were no urban centres and the economic basis of the society was cattle and corn. An overwhelming proportion of the cattle seems to have consisted of cows, and milk and its products appear to have constituted an extremely important part of the national diet. The land was tilled with the plow which was drawn by oxen harnessed to it by wooden shoulder yokes. The grain crops were oats, barley and wheat, in that order of importance, the grain from which was dried in kilns and ground in mills of the horizontal type or in rotary querns and eaten as porridge or bread. Sheep appear to have been bred principally for their wool and the only animal reared specifically for slaughter was the pig, the flesh of which was eaten fresh as pork or salted as bacon. Fish were taken with hooks, nets and spears or in weirs erected on rivers. Hunting, fowling and trapping supplemented the diet in a small way and large wooden deer traps have been found preserved in bogs. There is one representation of a deer caught in such a trap on a sculptured slab of the period from Banagher, County Offaly. Wool was spun with a wooden spindle weighted with a whorl of bone or stone and woven on a loom. The outer garment worn by both sexes was an ample woolen cloak called a *brat* which was fastened on the shoulder or the breast by a pin or one of the large brooches of the Tara type described above. The inner garment was a long linen tunic, called a *leine*, which was girded at the waist with a belt or *crios*. Shoes of rawhide or tanned leather were worn, at least by the upper classes and the higher professional ranks. A large number of these shoes have been found in bogs. Each is made from a single piece of leather, sewn with gut or thong. Some are provided with small ornamental tongues which lay on the wearer's instep and some specimens have these tongues delicately tooled with patterns which enable them to be dated to this period. The chief musical instrument was the harp and harpists are depicted in many scenes on the high crosses. Transport of goods by land, insofar as there was any need of it in a society composed of self-sufficient local communities, was by pack horse, for wheeled vehicles appear to have been few. In the earlier part of the period a chariot drawn by two horses harnessed to a central pole was in use, perhaps mainly as a vehicle of parade. If the scenes where it is depicted on the high crosses can be trusted to reflect contemporary life, it remained in use up to the 10th century, but there is no evidence to show when it finally disappeared. Sea transport was accomplished by currach, a wicker-framed boat covered with hides, propelled by paddles and sometimes fitted with a sail also made of hide. On inland waterways, the currach may also have been used but, to judge by the great numbers of them discovered in lakes and rivers everywhere in the country, the normal freshwater craft was the dugout, which remained in common use to the 17th century.

The houses of the time were built after the post-and-wattle technique but the data about them which can be gathered from the ancient literature are vague and very little has yet been discovered by excavation. Some, at least, of these houses were situated within the protected sites called ring forts, of which tens of thousands still remain. A typical ring fort consists of a circular outer ditch, the upcast from which was used to build a concentric bank around the margin of the enclosed level space, the bank being, no doubt, topped by a wooden palisade. Excavations carried out at Carrigillihy, County Cork, and at Lough Gur and Cush, County Limerick, show that a possible prototype was in existence in the country during the early and late phases of the Bronze Age and other excavated examples prove that it was a normal place of habitation down to medieval times. Larger defended habitation sites were often surrounded by a number of concentric banks and ditches. In parts of the country where surface stone was plentiful, the ring fort was replaced by a stone fort, commonly called a cashel: a circular enclosure ringed by a massive dry-built wall pierced by a single linteled doorway. Forts of this kind are espe-

cially numerous in County Clare and some of the most impressive examples are to be found in the Aran Islands, off the Galway coast, that known as Dun Oengus being the most formidable. Many ring forts are provided with complexes of underground chambers and passages called souterrains, which may have been used both as refuges and storerooms. Souterrains also occur where no visible indications of former habitation remain but these may have been connected with unprotected wooden dwellings long since vanished.

Advantage was also taken of the relative security afforded by islands in rivers and lakes as dwelling places, and artificial islands, called crannogs, were extensively made to supplement the limited number of natural sites. Crannogs vary greatly in size but all consist of material mounded up on the lake bottom on rafts of brushwood and held in position by rows of piles driven in round the perimeter and through the mass itself. There is some evidence that the custom of constructing them goes back to Neolithic and, perhaps, even to Mesolithic times, while they are well attested from the Bronze Age. They were commonly inhabited during the early Christian period and they were, in some cases, tenanted up to the 16th century. Partly because they have been undisturbed by agriculture and other activities and partly because of the preservative effect of their waterlogged soil, such crannogs have yielded exceedingly numerous and varied finds. Among the richest hitherto investigated are those of Lagore (County Meath) and Ballinderry (County Offaly).

With the arrival of the first Anglo-Norman invaders in County Wexford in 1169 this outline of the archaeology of Ireland may be brought to a close for with that event a new era opens in Irish history marked by a rapid decay of many of the native arts, the introduction of new styles in architecture and the imposition of the feudal system on much of the country. (A. T. Ls.)

V. HISTORY (TO 1921)

Earliest Inhabitants.—The earliest-known remains of human habitation in Ireland are assigned by archaeologists to the period of the transition between the early and the late Stone Age. This period, it is held, was preceded by intense glacial conditions, covering the whole island and extending also over Britain as far south as the estuaries of the Severn and the Thames. The Neolithic and early Bronze periods which follow are well represented in Ireland, but their data belong rather to archaeology than to history. The later Bronze Age in Ireland, though it has no documents, native or extraneous, has left evidences sufficiently abundant and vivid to be considered historical. To it belong numerous tombs of massive structure, surmounted by great tumuli of earth or stones, the stone slabs in some of them being carved with a great variety of designs, symbolic or ornamental—evidence of a settled population under opulent rulers. Bronze was abundant. There were rich copper mines, but no tin mines, and the tin which was needed to make bronze must have been an article of import, no doubt from Cornwall, during the whole of the Bronze Age and later. The distinctive feature of this period in Ireland was the production of native gold, of which it is certain that there were comparatively rich deposits in the Wicklow mountain region. Irish gold ornaments of the Bronze Age have been found in various parts of Britain, in northern France and in Luxembourg, Hanover and Denmark. In Ireland the principal finds have been in districts far away from the gold-producing region. Finds of the ancient apparatus of bronze founding are likewise recorded in places far away from copper mines and from seaports through which tin could be obtained. The facts point to a development of commerce, internal and external.

To the Celts of Gaul, and through them to the Greeks, the ancient inhabitants of Britain and Ireland appear to have been known by the common name of "Pretani." The two islands, Albion and Iverne (Hiberio, thence Eriu, Eire), are called in Greek the Pretanic Islands. In Latin and first, so far as is known, by Julius Caesar (d. 44 B.C.), the name "Brittani" (becoming later Britanni and Brittones) is substituted for Pretani and used distinctively of the people of the larger island, to which the name "Brittania" (Britannia) was given. "Pretani," represented in early Irish by "Cruithin," was the name of the people who in later times are known as Picti, Picts (*q.v.*). Hence it may be inferred that during the later Bronze Age the Picts were the chief people of Ireland as well as of Britain, and this inference is amply confirmed by ancient Irish traditions.

Celtic Colonization and Civilization

Arrival of the Celts.—During the historical period Ireland was a Celtic country, deriving its civilization either directly from the continent of Europe or indirectly from the continent through Britain (*see* CELT). The extent to which Celtic civilization spread indicates extensive colonization and it thus becomes important to try to determine when the Celts came to Ireland. Many distinguished scholars have provided answers to this question: linguists such as D'Arbois de Jubainville, Sir John Rhys, Thomas Francis O'Rahilly, Julius Pokorny; archaeologists such as Joseph Déchelette, Henri Hubert, Adolf Mahr; historians such as Camille Jullian and John MacNeill. No two of those mentioned agree among themselves and the differences are irreconcilable. The first great problem concerns the Picts. If these were a Celtic people, Celtic colonization is likely to have taken place 1,000 or more years before the Christian era. Though this is possible it cannot be said to be probable. The evidence in favour of a Celtic origin for the Picts is linguistic (*see* CELTIC LANGUAGES); there are clear traces of the use among the Scottish Picts of what philologists call a P-Celtic language cognate with Brythonic and Gaulish. On the other hand the evidence is equally clear that another language, apparently not a member of the Indo-European family, was employed in Pictish inscriptions down to the collapse of the independent Pictish kingdom in the 9th century A.D. There is also political and social evidence pointing to the existence among the Picts of the principle of matrilinear succession, an institution foreign to the Celtic states of the European continent and to the Celts in Ireland. Nor does the earliest stratum in Irish literature lend support to the theory of common origin; for there the distinction between the Irish and the Picts is so sharply drawn that it is difficult to visualize the two as mere divergent branches from the same Celtic stem. A likely explanation, put forward with convincing argument by Kenneth Jackson ("The Pictish Language," in *The Problem of the Picts*, edited by F. T. Wainwright, 1955), is that a section of the Picts in Scotland had adopted, perhaps at a quite remote period, the Celtic language spoken by their neighbours.

Traces of another language group, Q-Celtic, are rare in continental Europe. In the period of the Roman conquest of Gaul the language spoken by the various peoples was P-Celtic. The same holds true of Britain. Assuming that so striking a peculiarity is very ancient, the Q-Celts who traveled from the continent to Ireland and ultimately imposed their rule on the whole island must have migrated some centuries before the beginning of the Christian era. We know that migration on a large scale was taking place along the Danube and to the south and east in the 5th century B.C. It is likely that a corresponding movement toward the west resulted in the Celtic colonization of Ireland in the same century. In corroboration of this date two facts deserve mention. The way of life of the Celts in Ireland and the way of life of the Celts of Gaul, as described by Julius Caesar, are so very similar that the separation cannot properly be placed too far back in time. On the other hand, the historical memory of the Celts in Ireland, which reached back to the beginning of the Christian era, knew nothing of Gaulish origins. Even in the conservative field of religion the pantheons of the Celts of Gaul and of the Celts of Ireland were no longer the same. The lapse of time between colonization and the earliest remembrance in Irish Celtic tradition must therefore have been considerable. As a suggested date for the migration, the 5th century B.C. is sufficiently close to the time of Caesar's Gaul (1st century B.C.) to explain the substantial unity in civilization and sufficiently removed to explain forgetfulness of the circumstances of migration. No greater precision can be achieved from the archaeological evidence.

Celtic Institutions.—Like their forebears on the continent the Celts in Ireland established themselves in small states. The com-

mon term for each of these states in Old Irish was *tuath*. Over the people of each state was the elected leader who bore the title of *rí*, "king." The constitution was completely monarchic. In Gaul, before the Roman conquest, a number of states had become republics ruled by presidents; in Ireland there is not the slightest hint of any such change. The king governed his people, gave judgment in cases of dispute, a task in which he was assisted by professional lawyers (*brithemain*), and commanded the military forces. Round the king stood his council (*airecht*) of nobles. They and the freemen of the state came together at regular intervals in an assembly (*aenach*) to discuss matters of common interest and to determine policy. A well-known territorial unit was the *tricha cét*, corresponding, Giraldus Cambrensis says (*Topographia Hibernica*, iii, 5), to the Welsh *cantref*, 100 households (*villae*). There was a common law (*urradas*) and the occasional special law (*cáin*) passed by an assembly or promulgated by a king. A freeman had full franchise in his own *tuath*, but was a noncitizen (*deorad*) elsewhere, though with rights beyond those of the foreigner (*allmurach*) or the outcast (*muirchuirthe*). Common jurisdiction (*cairde*) between states could be established by mutual agreement.

Among the Celts every freeman struggled to maintain the maximum of personal independence and the states, however small, strove desperately to achieve and maintain political independence. But this proved to be impracticable; for self-protection the small states had of necessity to gather themselves into groups and accept the hegemony of a superior king.

About the beginning of the Christian era the groups had taken permanent shape and appeared as five major states, the Five-Fifths (*cóic cóicid*) of Ireland. These were Ulster (Ulaid), Meath (Mide), Leinster (Laigin), Munster (Muma) and Connaught (*q.v.*; Connacht or Connachta). The last-named is also called in early documents the Cóiced nOléccmacht and this may have been the original name. Ulster had its chief fortress or centre of rule at Emain Macha (Navan Fort) near Armagh. Meath had as its centre, or capital, Temuir (Tara); Leinster a central stronghold at Ailend, in Kildare; Munster a similar stronghold known (probably by analogy with the more famous capital of Mide) as Temuir Érann, near Ardpatrick in Limerick; Connaught its centre at Crúachu (Rathcroghan) in Roscommon.

Among the landed freemen the noble (*flaith*) was distinguished by the possession of greater wealth and by a following of clients (*céli*). *Flaith* means both "lord" and the state of being a lord or nobleman. The *céle* rendered service to the lord at least to the extent of acknowledging dependence on him and accompanying him as a mark of honour. It is not clear that the term *céle* connoted of necessity economic dependence on the *flaith*, but that such a relationship was known is beyond question. There were *céli* who received from the *flaith* capital in the form of cattle and who paid interest at a fixed rate until the capital was paid back. Such *céli* were *saerchéli* (free tenants) or *daerchéli* (the legally unfree) according to the conditions on which the capital was lent. To the *daer* class belonged the *aithech* ("he who pays rent") and those beneath him in the social scale. While the position of the *aithech* was conceived as low, there were rich farmers (*briugaid*) whose social standing was almost that of a *flaith*. A disadvantage of their position was the obligation to provide hospitality on a generous scale; at times, indeed, to supply provisions to a whole army. In the inferior world of service was the *gilla* (personal servant) and the *inailt* (housemaid); and at the bottom of the ladder the man slave (*mug*) and the female slave (*cumal*).

The Druids.—Druidism (*q.v.*), known only in transalpine Gaul, Britain and Ireland, but not recorded in Britain outside Anglesey and the northern Pictland, is unlikely to have originated in Ireland. The druids may be described as an association of professional wise men, philosophers in the early Greek sense, claiming to be experts in all the higher branches of knowledge. They professed special knowledge of the gods, the other world, the future life, the form and measurement of the earth, the movements of the heavenly bodies, the history of men; and they were accepted as authorities in matters of religion and law. They also claimed occult and prophetic powers. In the Roman world, after their suppression by the state, and in Ireland, after its conversion to Christianity, they were chiefly remembered as soothsayers and magicians. The notion that they were the priests of a particular religion is of modern growth. In Christian Ireland the druids continued to exist, but with a change of name and with limited scope. They were called *filid*, a name which in time became restricted to the meaning of poets (*see* IRISH LITERATURE: *Gaelic Literature*) but which originally, signifying seers, denoted one of the functions of the druids. They no longer had authority in matters of religion but they long continued to practise occult rites of divination. As exponents of learning they were largely displaced from the ground covered by the Latin teaching of the ecclesiastical schools, but remained for long the authoritative exponents of the national history, literature and law. In Gaul, notwithstanding the division of the country into so many independent states, the druids formed a single society, with annual conventions and an elected president. In Ireland the *filid* did not present this organized form, but they maintained an effective unity through a long course of centuries. They provided a single code of law for the whole country. They followed a common literary usage in writing and in minutely regulated rules of prosody which they all accepted. What Caesar tells of the long course of education of the Gallic druids and of the instruction given orally and in verse is paralleled in the *filid*. Like the druids, they enjoyed civil immunities. Their persons were sacred. The influence of druidism remained operative and distinctive in Irish history throughout medieval times. It can be traced in the conversion of the Irish to Christianity, in the development of the monastic schools, in Irish law, in the form and content of Irish literature, and in lasting pedantic tendencies; but its most important effect was the forging of a national consciousness in no way dependent on political cohesion.

The Septs and the Early Monarchy.—In the sagas of the Ulster cycle (*see* IRISH LITERATURE: *Gaelic Literature*) strong rivalry is suggested between the Ulster and the Connaught kingdoms, but the queen of Connaught, Medb or Maeve, was herself a Mide princess and the chief political feature of the early Christian centuries was the rise of the midland dynasty to a position of great strength. The steps in this advance are not easy to follow, since the sources are literary rather than historical, and the exploits of Conn (*q.v.*) of the Hundred Battles and Cormac Mac Art (fl. *c.* A.D. 275) who figure as powerful kings of Ireland in the Mide genealogical tree, may be little more than poetic inventions. That there was, however, such an advance is abundantly clear. The Ulster kingdom was reduced in extent and in status and even threatened with complete annihilation. In the 4th century A.D. princes of the Mide dynasty made an incursion into mid-Ulster. They were entirely successful. The result was the formation of a new kingdom, known as Airgialla, independent of the Ulster kings. About the same time princes of the Mide dynasty are found ruling in Crúachu, the capital of Connaught. As the fortunes of Mide prospered, the prestige of Tara rose. In the early 5th century the midland kingdom reached the pinnacle of glory. Its ruler then was Niall of the Nine Hostages (d. 405), a man renowned beyond any of his predecessors for energy and ability. Under his direction the western portion of Ulster was occupied and colonized by his sons, Eogan, Conall and Enda. Their descendants were henceforward supreme in Ulster and the kingdom established by Eogan and his descendants, the Cenél nEogain, which was generally called Ailech after a great stone fortress that overlooks Lough Foyle near Derry, ranked as a leading state in the country.

At the same time the other sons of Niall, moving east and west from a centre near Kells, established themselves as princes across the midland kingdom "from the Shannon to the Irish sea," Conall occupying the Tir Conaill (modern Donegal) and Enda taking land farther east. Niall's brothers ruled in Connaught. His relatives ruled in Airgialla (Oriel), the new kingdom in mid-Ulster. Within that territory lay Emain Macha, the ancient capital. With it the Ulaid lost their whole kingdom save an eastern strip, the modern counties of Antrim and Down and about a third of Louth. There they were to remain, mindful of their

former greatness, doggedly defending their local autonomy, to the days of Shane O'Neill (d. 1567) and beyond.

To the chroniclers Niall of the Nine Hostages was king of Ireland (*Rí Érenn*). The title marks the conclusion of a process of unification, first the gathering of innumerable small *tuatha* into five major states; next the control of the northern states (Leth Cuinn, Conn's Half) by the dynasts of Mide and a similar control of the southern states (Leth Moga, Mog's Half) by the dynasts of Munster. In the last-mentioned kingdom (*see* MUNSTER) the Eoghanachta (not connected with Niall's son) had succeeded the Érainn as the ruling population group. They had moved to Cashel (*c.* 400) and made the great rock their chief fortress and the symbolic capital of the Munster state. They had crossed the Shannon and deprived the Connaught kingdom of the region later known as the county of Clare. They had established princes of their house who became the ancestors of ruling septs in Limerick, Cork, Kerry, and even beyond the sea in Wales. Despite this outburst of activity, or perhaps because of it, since it meant urgent preoccupation with the affairs of southern Munster, they allowed the predominant place in Ireland as a whole to go unchallenged to Niall of the Nine Hostages and his descendants. It is to be noted that the title of king of Ireland did not give the ruler who bore it administrative or legislative rights over the country; it did, however, confer immense prestige, reflected generally in the size and strength of the king's army. Niall's nephew Nathi (d. 428) and his grandnephew Ailill, both kings of Connaught, were kings of Ireland also but with the defeat and death of Ailill at the hands of Niall's direct descendants in the battle of Ocha (482 or 483) the claim of Connaught collapsed. It was to be revived by the O'Connor kings of Connaught in the 12th century.

Meanwhile, no fewer than 42 of Niall's descendants became kings of Ireland—an extraordinary roll of honour. They maintained their supremacy against several attacks. For instance, Domnall Brecc, king of Dalriada, crossed from Scotland to Ireland in 637 to assist the Ulaid in an attack on the Uí Néill. They were utterly defeated by the king of Ireland, Domnall, son of Aed, son of Ainmire, in the battle of Mag Roth, somewhere in the southern half of Down. Two branches, the Cenél nEogain, of the northern Uí Néill, and the Clann Cholmáin of the southern Uí Néill, alternated as kings of Ireland from 734 to 1002, a fact which suggests a formal arrangement between the two septs. The Leinstermen resented their hegemony but were unable to shake it off, though they won more than one important battle in the field. When the power of the Eoghanachta was widely and firmly established, they became restive in their position of formal subservience, little as the high kings interfered with their government or restricted their exercise of independence. A challenge was thrown down once in the 8th century and once again in each of the two following centuries but always without success.

Rural Economic Development.—The Irish laws point to a large development of rural industry in the period in which they were first written, preceding the Norse incursions. They deal minutely with the enclosure, subdivision and fencing of lands for tillage, the measurement and valuation of land, the management of crops and domestic animals, and innumerable details of husbandry, including milling, dyeing, spinning and weaving, dairying, malting, meat curing, etc. The principal crops were wheat, barley, oats, flax and hay. Dyestuffs were grown. Irish hounds were in high repute. St. Patrick, in his escape from captivity, joined a company of Irish traders whose chief merchandise was hounds. Watermills were owned and worked jointly by landholders.

Irish Raids and Migrations.—From about the middle of the 3rd century, Latin writings bear constant evidence of Irish raiding expeditions, and the older Latin name Hiberni or Iverni is almost wholly replaced by a new name, Scotti. Linked with the Scotti are found the Atecotti, a Celtic word meaning "the very ancient folk," and probably distinguishing the Irish of pre-Celtic origin from the dominant Celts. Irish tradition fully reflects the evidence of Latin writers. As the Roman power weakened in Britain, Irish raids were followed by migratory settlements. Irish dynasties sprang up in Wales and lasted there for centuries. In the 5th century, the kings of Dalriada, a small kingdom in the northeastern angle of Ulster, extended their power over the Irish settlers in Argyll and the neighbouring islands, their descendants ultimately, in the 9th century, becoming kings of Scotland. Niall of the Nine Hostages has been identified with "the Scot" who, in Claudian's poem *De consulatu Stilichonis* (ii, 251), "mobilized all Ireland" against Roman Britain. In his reign St. Patrick was carried to Ireland as a captive. At the head of a later expedition, Niall was killed at sea by a Leinster prince. His successor, Nathi, heading another raid, died on the continent.

Early Christianity

The Early Missionaries.—Quite apart from the thousands of enslaved Christian captives, there is evidence of Christianity in Ireland before the first Roman mission arrived there. In 429, at the instance of Palladius, deacon of the Roman church, St. Germanus, bishop of Auxerre, was sent by Pope Celestine I to combat the Pelagian heresy in Britain. It was doubtless in answer to an appeal made through Germanus that, in 431, "Palladius himself was sent, their first bishop, to the Scots believing in Christ." Apparently, after a short stay in Ireland, Palladius went to northern Britain, where he soon died. Very shortly afterward (the traditional date is 432), Patrick, a disciple of Germanus, was sent as bishop to Ireland. He was a Briton, son of a decurion under the Roman government, and probably a native of some small town near the river Severn. He was carried off as a captive (*c.* 401) in the reign of Niall and became a slave in northeastern Ulster. After six years he escaped. His mission in Ireland succeeded rapidly. He was favourably received at the court of the high king, Loiguire, son of Niall. In 439, doubtless in answer to a request sent to Germanus, three bishops were sent to his assistance, Secundinus, Auxilius and Iserninus. Patrick chose for his own see Armagh, beside the ancient Ulster capital. Secundinus had his church near Tara, the seat of the high king; Auxilius, near Naas, also a royal seat in Leinster; Iserninus, driven out at first by Enda, king of Leinster, was restored later by Enda's son Crimthann, a Christian convert, and fixed his see at Aghade, near Rathvilly, where Crimthann lived. There is evidence that Patrick chose Baislec (Basilica Sanctorum), near Crúachu, the capital of the kings of Connaught, as the see of a bishop for that kingdom. (For the conflicting views concerning the life of St. Patrick, *see* PATRICK, SAINT.) In the story of St. Patrick's reform of Irish law one might see an influence transformed by tradition into an event. A druid foretold to Loiguire: "He shall free slaves, he shall raise up men of lowly kin." In the written laws, two centuries later, a slave class no longer existed. St. Patrick's epistle condemns the enslavement of Christians. The earlier racial distinctions between conquerors and conquered survive only in antiquarian tradition, and all become known by the name Goidil (Gaels) or Fir Erenn (Men of Ireland).

Irish Monasticism.—Though monks and monasteries were to be found in Ireland in the days of St. Patrick their place was altogether secondary. A great change took place in the course of the 6th century, so great that by the year 600 the church in Ireland had become monastic in organization. Why this happened is not easy to explain. The monastic ideal appealed obviously to the religious vein in the Irish character, and the loose monastic system, based on a multitude of independent foundations, was in harmony with state institutions. Daily experience tended to show that this was the mold within which the church could grow and prosper. The influence of monasteries from Britain, such as the Candida Casa at Whitern in Galloway, the Llangarvan of St. Cadoc and later the Menevia of St. David, increased this tendency. A patriarch of monasticism in its typically Irish form was St. Finnian (d. *c.* 589) of Clonard. Among his disciples who became in their turn founders of distinguished monasteries were St. Columba (*q.v.*; Derry and Durrow), St. Ciaran (Clonmacnoise) and the two Brendans of Clonfert and Birr (*see* BRENDAN, SAINT). St. Congall's monastery at Bangor in the Ards of Ulster was hardly less important. Convents of women were relatively few compared with communities of men, but the foundation of St. Brigit (*q.v.*) at Kildare was of high repute. Beside the community of women lived a community of men, ruled by a bishop, and for Mass and

for the divine office the two communities used the same church, divided only by a high partition wall of wood. Kildare was thus a double monastery, the one example of its kind in Ireland.

Though there was variety in detail there was so much similarity in the practice of the Irish monks and nuns that it is possible to speak of an Irish monastic observance. Its characteristics were severity in the discipline of the body and zeal in the cultivation of the mind. This is the justification for the title *insula sanctorum et doctorum*. The Venerable Bede bears eloquent testimony to the reputation enjoyed by the Irish schools of the 7th century, and to the hospitable reception given there to students from other lands. While the abbot represented ecclesiastical power, the bishop held the highest ecclesiastical dignity, for to him were reserved the supreme episcopal functions, such as the ordination of priests and the consecration of churches, and his "honour-price" was equal to that of a king. The *Fer Léginn*, "man of learning," was president of the monastic school.

Scholarship and Missions.—In these schools the language especially prized was Latin. Not only the works of the Fathers of the Church but the secular classics were held in high esteem. Greek texts, on the other hand, were scarce, and those who could claim a deep knowledge of that language were few. Noteworthy in this connection is Johannes Scotus Erigena, a teacher in the Frankish kingdom under Charles II the Bald. Erigena translated various neoplatonist treatises from the Greek, wrote poems in that tongue, and composed a philosophical and theological work of remarkable quality, which he called *De divisione naturae*. Poetry in the native classical metres is found in the Irish language about the year 600. An older form of rhythmical alliterative verse, curiously similar in structure to verse in ancient Latin, is found scattered through the sagas. The new syllabic poetry, usually called *dán dírech*, of which specimens survive from the end of the 5th century, was based on the Latin hymn poetry of the early Christian centuries. Though its construction was rigid there was room for variety; 44 different metre forms have been noted. From the early 7th century onward Irish written literature in prose and verse is extensive. In art, too, especially in metalwork and in illumination of manuscripts, progress was marked. Architecture remained backward and cramped, no doubt because of the tradition of political unrest: a noble and spacious building would be too tempting a target for an invading army.

The Irish proved to be zealous missionaries. From the island of Iona, St. Columba directed the evangelization of the pagan Picts of Scotland. Success in this field was absolute. Until the time of St. Margaret (d. 1083), queen of Malcolm III, the church in Scotland was an offshoot of the church in Ireland, hardly distinguished from it in spirit, organization and customs. Iona also sent missionaries to England, first to Northumbria, then to Mercia, East Anglia and even as far south as Wessex. The work of these was impeded by the Paschal controversy. Ireland had received its method of computing the Easter date (the cycle of Augustalis) from Britain. This system differed from the Alexandrian cycle, followed by the Roman missionaries of the 7th century, and which was accepted in the southern half of Ireland *c.* 632. It was not accepted in the north, however, the part of Ireland to which Iona belonged. A clash between the archaic Irish system and the Alexandrian system led to the withdrawal of the Irish clergy and monks to Iona from Northumbria after the synod of Whitby (663 or 664). While the churches of northern Ireland adopted the Alexandrian cycle in the late 7th century, Iona did not submit until 716. Even then the reason for submission was not the conviction that the Alexandrian system was mathematically correct but the desire to be in harmony with the apostolic see.

Norse Invasion and Settlement

The first appearance of the Northmen on the Irish coast is recorded in 795. Thenceforward there were frequent plundering raids, sometimes far inland. By degrees the Norse took possession of all the islands of Scotland, of Caithness, Argyll, Galloway and of the Isle of Man. In 838 they seized and fortified two ports, Annagassan, between Dundalk and Drogheda, and Dublin. About the same time a fleet under a Norse leader, Thorgest (Turgeis), passed up the Bann to Lough Neagh. He afterward sailed round to the Shannon and took possession of Lough Ree in like manner. Thorgest was captured in 845 and put to death by Maelsechlainn, king of Mide, who in 846 became king of Ireland. Large invading forces were defeated in 847. The turning point of these invasions was reached in the reign of Aed Findliath, high king from 862 to 879, who forced the Northmen to abandon all their stations in the northern parts of Ireland. At the same time the Norse kings of Dublin reached the height of their power, waging war in England and Scotland, and so disturbing normal life in Ireland that in 873, 876 and 878 the high king was unable to hold the national assembly of Tailtiu. Waterford in 914 and Limerick in 920 were occupied by the Northmen without opposition. In 917 Niall Glúndub, high king, endeavoured to dislodge them from Waterford but was defeated and forced to withdraw. In 919 Niall led an army against Dublin, and in a battle where the Phoenix park now lies he was defeated and killed. The permanence of the Norse settlements in Dublin, Waterford and Limerick became assured. Landed colonies spread out from Dublin and Waterford. Without quite abandoning piracy, the vikings became traders in close intercourse with the Irish, and their commercial towns formed a new element in the life of the country, typified in Wexford, which did not appear in warfare until the siege of 1169. The combination of war and commerce led to a recrudescence of slavery, and imported slaves are mentioned in the *Book of Rights* (about A.D. 900).

About 964 Mathgamain, king of Dal Chais, one of the petty kingdoms of Munster, became king of Munster, displacing the ancient Eoghanachta line. In 968 he defeated the Norse of Limerick and captured their city. In 976 he was captured and put to death by two Eoghanachta princes, one of whom, Mael Muaid, then became king of Munster. In 978 Mael Muaid was defeated and put to death by Brian, brother of Mathgamain. Brian, having gained the kingdom of Munster, steadily increased his power. His claim to suzerainty over Leinster forced the Leinster king into close alliance with the Norse of Dublin. In 999 their united forces were defeated by Brian at Glenn Máma, near Dublin, and they agreed to become his allies and supporters. In 1002 Brian became king of Ireland by the submission of the high king Maelsechlainn II. The Irish and Norse accounts agree in bearing witness to the high character and good government of Brian. The kings of Dublin and Leinster, however, chafed under his authority. In 1013 Sigurd, earl of the Orkneys, had for a Christmas guest the Norse king of Dublin, Sigtrygg, and a compact was made between them. Sigurd was to gather from all parts the greatest possible host of Northmen and to bring them before Easter to Dublin, where they were to be joined by the forces of Dublin and Leinster to give battle to Brian; if they were victorious, Sigurd was to have the kingdom of Ireland. Brian learned of these preparations and met the Norse army at Clontarf, near Dublin, on April 23, 1014. The Northmen and their Leinster allies were defeated and Earl Sigurd was slain, but a viking chief, who had taken refuge in a wood, sallied out in the rear of the Irish army and killed Brian in his tent.

Though the battle of Clontarf removed the prospect of a Norse conquest, it brought a period of unsettlement. All the chief dynasties had lost their prestige, and, except in Connaught, new rivalries and fresh pretensions to power, based on force and careless of tradition, arose everywhere. Brian's son Murchad, who had already gained a reputation hardly less than his father's, had fallen in the battle. Of the sons who survived, none was able to sustain Brian's power. Maelsechlainn was restored to the high kingship and held it until his death in 1022. After him for half a century there was no acknowledged king of Ireland.

Then followed the period of the high kings "with opposition," *i.e.*, not acknowledged by a minority of the provincial kings: Toirdelbach (Turloch, d. 1086), grandson of Brian, and his son Muirchertach (d. 1119), kings of Munster; in opposition were Domnall Ua Lochlainn, king of Ailech, who died in 1121; Toirdelbach Ua Conchubair (Turloch O'Connor, d. 1156), king of Connaught; Muirchertach Ua Lochlainn (d. 1160), king of Ailech; and Ruadri Ua Conchubair (Rory O'Connor, d. 1199), king of

Connaught, who lost his power as high king to Henry II of England in 1175. The centralized feudalism established in England by William the Conqueror had some influence on the policy of these kings. One after another they sought, for the most part without success, to set aside ancient tradition and exercise direct authority outside their hereditary jurisdictions. Thus Toirdelbach Ua Conchubair in 1118 divided Munster into two coequal kingdoms; in 1125 he deposed the king of Mide and appointed three kings in his stead; in 1126 he made one of his sons king of Dublin and Leinster; and in 1129 he built the first castle in Ireland, commanding the passage of the Shannon at Athlone.

The last effort to establish Norse domination was made by Magnus II, king of Norway, who in 1098 restored the Norwegian sovereignty over the Scottish islands, Cantire and the Isle of Man. In 1103 he landed on the Ulster coast, and was slain by a local levy while endeavouring to bring a "shore-killing" of cattle to his ships.

The period of political ferment which followed the success of Brian over the ancient chief dynasties was also a period of new growth in religion, literature and the arts. The movement for religious reform, mainly in the direction of a Catholic uniformity and the removal of abuses in matters of ecclesiastical discipline and observance, was led by Gillebert, bishop of Limerick, and Cellach (Celsus), bishop of Armagh and primate, in the beginning of the 12th century, and by the successor of Cellach, Maelmaedoc Ua Morgair, better known as St. Malachy (*q.v.*). The outstanding feature of the abundant literary output of this time is enthusiasm for ancient national tradition. It became customary to compile tomes, each forming a kind of library of traditional lore, comprising sagas, poems, genealogies, etc. A number are still extant.

(J. J. Ry.)

First Centuries of English Rule

The Anglo-Norman Invasion.—As early in his reign as 1155, Henry II of England had through his envoy, John of Salisbury, received from Pope Adrian IV the grant of Ireland "as an inheritance," on condition that he should reduce to order the Irish church and state. The so-called "bull," *Laudabiliter*, which defines this grant, rests on the sole authority of Giraldus Cambrensis; how far it is genuine is one of the puzzles of history, but the general submission of the Irish to Henry in 1171–72 would imply that some such papal privilege had been issued.

Henry had to put his project aside for the time, and, when the invasion came, it was a feudal one and directed from south Wales, where there were many Normans looking for land and adventure. The first invaders, Maurice Fitzgerald, Robert FitzStephen, Raymond "le Gros" de Carew and others, were sons or grandsons of the famous Welsh princess Nesta and vassals of Richard de Clare, 2nd earl of Pembroke (*q.v.*), called "Strongbow" in Irish tradition.

Their opportunity came when Dermot Mac Murrough (*q.v.*), king of Leinster, expelled by his enemies, decided to seek aid in England and arrived in Bristol in Aug. 1166. He was referred to Henry, found the king in France, was graciously received and given permission to raise forces in Britain. Returning to Wales, he won Strongbow over by the offer of his daughter's hand with apparently the succession to Leinster. He also enlisted "the sons of Nesta" in his cause, and they found volunteers among the Welsh and Flemings of south Wales and Pembroke. Returning to Leinster, where his son Donal Kavanagh, whom Giraldus calls illegitimate, was holding out for him, he held his ground until successively Fitzgerald, FitzStephen, Raymond and finally Strongbow himself arrived, the latter landing at Waterford in Aug. 1170 with 200 knights and 1,000 men-at-arms.

The successes of Dermot, backed by these professional fighters, were rapid; Danish Waterford was taken, the marriage of his daughter Eva and the earl celebrated, and by a rapid march Dublin also was captured and a relieving force under the high king scattered, late in 1170. Leinster and Ossory were reduced, but the death of Dermot the following May made the situation difficult. The Irish regarded his son Donal as the true heir, but Strongbow considered himself king of Leinster, and in feudal theory he was, in virtue of his wife, lord of the province. But he was hemmed up in Dublin in midsummer by a national levy raised by Roderic (*q.v.*; Ruadri, or Rory O'Connor), king of Connaught, and though this attack was repelled it was uncertain whether he could hold his own. Therefore when Henry, fearful lest a new Norman state should arise across the Irish channel, resolved to come to Ireland, Strongbow placed his conquests at his suzerain's feet.

Henry landed near Waterford on Oct. 17, 1171, with an imposing army, but a conquest in arms was not necessary, and in fact the peaceful submission of the Irish leaders was prompt and widespread. The king marched to Lismore and Cashel and finally to Dublin, where he spent the winter, leaving Ireland on April 27, 1172. In this short period he managed to set up the rough essentials of a government. At Dublin and elsewhere he received the homage of all the kings of Ireland except those of Connaught and Ulster. To Strongbow he granted the land of Leinster; he confirmed the Geraldines and others in their fiefs, and annexed to the crown the Danish kingdom of Dublin. He gave the capital to "the men of Bristol," took the Ostmen (the Danes) under his protection and appointed as governor of the colony Hugh de Lacy, 1st lord of Meath (*q.v.*). He did not scruple to confer the whole of Meath on De Lacy, though its native king, O'Melaghlin, had recently submitted, and the grant illustrates the inevitable clash of feudal and Irish law. Meanwhile during the winter the Irish bishops met at the synod of Cashel and, after enacting various reforms, declared (according to Giraldus): "Divine offices shall be celebrated according to the forms of the English church, for it is just and right that as Ireland has received her lord and king from England, she should accept reform from the same source." This of course was an inspired assurance of the task with which the papacy had commissioned Henry. The submission of the church was complete, at least in theory. Christian, bishop of Lismore and papal legate, was on Henry's side; Laurence, archbishop of Dublin, and the native prelates of Armagh, Cashel and Tuam were also present.

Meanwhile the adventurers were attacking Desmond, though its king had submitted to Henry; De Lacy was organizing Meath, and John de Courci (*q.v.*) conquered in Antrim and Down a principality for which he could show no royal patent. Strongbow enfeoffed many Normans with land in Leinster, giving the barony of Naas, for instance, to Maurice Fitzgerald. Strongbow died in 1176, leaving only a daughter, who later married William, the earl marshal, and brought to him "the land of Leinster." Ulster and Connaught were unconquered, and in 1175, by the treaty of Windsor, Henry acknowledged Roderic as king of Connaught under him.

English Overlordship.—At the Council of Oxford in 1177 Henry created his son John *Dominus Hibernie* and granted Desmond to Robert FitzStephen and Milo de Cogan. Eight years later (1185) John himself visited Ireland. A fresh series of grants was made, and William de Burgh and Theobald Walter "le Botiller" got wide lands in north Munster and Theobald de Verdun about Dundalk. The resentment of the Irish was shown in the assassination (1186) of Hugh de Lacy, and the lesson was taken to heart later in John's reign when Cathal Crovderg O'Connor, brother of Roderic, was confirmed in the kingdom of Connaught and Donnchad O'Brien in that of Thomond west of the Shannon.

Under John the lordship of Ireland was united with the English crown, and to this king belongs the credit of first establishing a civil government at the expense of the Norman adventurers. He dispossessed De Courci and gave the earldom of Ulster to Hugh, brother of Walter de Lacy, earl of Meath; but he soon repented of making this family too great, and in a personal campaign in Ireland in 1210 expelled them both. During his short stay in Dublin he organized a permanent government under a justiciar, and "with the common consent of all men of Ireland ordained that the laws and customs of the realm of England should be kept therein."

After his defeat over Magna Carta (1215), John had to restore the De Lacys, and the feudal caste under Henry III bent its energies upon the subjection of Ireland. When Richard de Burgh got a grant of all Connaught despite the claims of Felim O'Connor, conquered it and divided it among his followers (1235), and Maurice Fitzgerald acquired a claim to Tyrconnell, a complete conquest seemed probable. But during this period two great native dynasties arose in Ulster, the O'Neill and O'Donnell (*qq.v.*), and they repelled the Norman attacks, finding a new and potent weapon in

those professional fighters, the *galloglaigh* or galloglass ("foreign soldiers"), Hebrideans of mixed Gaelic-Norse blood who now began to flock into the north. On Connaught, however, the De Burghs kept firm hold, leaving to the O'Connors only a few cantreds of Roscommon. The power of this family was increased when in 1264, after the extinction of the De Lacys, Walter de Burgh, already lord of Connaught, was created earl of Ulster. The native Irish, though only partly successful, now broke the spell of Norman victory. Brian O'Neill was elected high king and raised a Gaelic confederacy, but was defeated and slain at Downpatrick in 1260. The MacCarthys overthrew a colonial army at Callan in 1261 and thenceforth ruled undisturbed over southwest Munster, their chief taking the name MacCarthy More. When Edward I granted (1276) to Thomas de Clare the "land of Thomond," later County Clare, Turloch O'Brien took up arms, and the De Clares were finally expelled in the war which ended in 1318.

In the early years of Henry III the central government was steadily built up. Magna Carta was sent over, the whole framework of English law was introduced, and Ireland had an administration under the justiciar and a parliament of peers and prelates, while the county organization was extended over the planted areas. An Irish exchequer was organized in 1200, and an Irish chancery in 1232.

Great numbers of the Gaels had fallen under Norman lords, and while some were already villeins (*betaghs*) under the old system, and remained so on the new manors, many of the colonists tried to reduce all Irishmen to the same level. Those living among the English and suffering from a denial of English law strove to procure it, but though the government was not unwilling the colonists opposed emancipation. The Irish who lived under brehon law (*q.v.*) had less desire to exchange it for English law, but under the pressure of the new domination they naturally aspired to have its legal advantages. The chiefs especially sought to have their tenures legally established under the crown, a benefit which, except in a few minor cases, had been denied them. To reconcile and blend two peoples so far apart in language and tradition was a huge task which only a resident monarchy could have achieved.

Under Edward I a second attempt was made to create a real central authority, and a series of justiciars, of whom John Wogan, who held the office from 1295 to 1307 and from 1308 to 1312, was the ablest, extended the area of common law and did something to reduce the feudal liberties. The baronial interest, however, was too strongly entrenched, and Edward had to placate it, giving "the land of Decies and Desmond" to Thomas, head of the Munster Fitzgeralds. In 1297 knights and the common clergy were included in the Irish parliament, and nine shires and five liberties sent representatives. In 1300 the towns also sent deputies, and thus Ireland received a legislative body which lasted till 1800. It was an Anglo-Irish assembly in which the native people had no spokesmen.

A series of disasters then shook the ill-founded state to its very base. Fresh from his victory at Bannockburn, Robert I the Bruce dispatched his brother Edward to win the crown of Ireland, which a league of Irish chiefs under Donal O'Neill, *Rex Ultonie*, offered to him. When Edward Bruce landed with an army of veterans near Larne in May 1315, almost all the natives rose in arms, and not a few of the older Anglo-Norman settlers joined him. He defeated Richard, the "red earl" of Ulster, at Connor. On May day, 1316, he was crowned king of Ireland on a hill near Dundalk.

The English cause was at last saved; Bruce failed to take Dublin, Felim O'Connor, at the head of a great Irish confederacy, was defeated and slain by a colonial levy at Athenry in Aug. 1316, and a new viceroy, Roger Mortimer, put spirit and energy into the government. Bruce himself was overwhelmed at Faughart, near Dundalk, by an army under John de Bermingham, and fell in the battle (Oct. 1318). Little or no vengeance was taken, and Mortimer was instructed to admit the aggrieved Irish to English law and liberty, an edict again without much effect.

The Irish Revival.—For a time all seemed fair, and the peerage between 1316 and 1329 was strengthened by the creation of new earldoms: that of Kildare (1316), given to John, head of the Leinster Geraldines (*see* FITZGERALD); that of Desmond (1329), given to Maurice, head of the Munster Geraldines; and that of Ormonde (1328), given to James Butler (*see* BUTLER). In Ulster the power of the earls then covered the whole coast from Carlingford to Derry. But an element of discord was found in the older colonists, who resented the dominance of the great lords, claimed that succession should go to heirs male instead of heiresses who conveyed lands to English absentees, and began to form clans of their own (*naciones et cognomina*). In 1333 the young earl of Ulster, William, was murdered by his own tenants, the Mandevilles, near Belfast, leaving only a daughter who later was married to Lionel, duke of Clarence. The O'Neills became supreme in mid-Ulster and the greater part of Antrim and Down, where they founded a new state, Clandeboy.

Connaught was at the same time lost to the English interest. Two cousins of the murdered earl, Ulick and Edmund de Burgh, seized on the family lands and founded, respectively, the Burkes of Clanricarde and Mayo, known to the Irish as MacWilliam Uachtair, "the upper MacWilliam," and MacWilliam Iochtair, "the lower MacWilliam." Though they maintained a certain English tradition of law and land tenure, spoke French and boasted their continental descent, they were obliged amid so Irish a population to speak Gaelic and marry Irish wives. As a result of such events an Irish revival alike in arms, language, law and civilization displayed itself in every part of the island, and the Gaels recovered large parts of Ulster, the midlands, Connaught and Leinster. Even in the latter province the Mac Murroughs became the terror of the lowland English, and the descendants of Donal Kavanagh resumed the title "king of Leinster."

Efforts to Restore Effective English Control.—Only a great army led by the king in person could have reconquered Ireland, and the young Edward III had thoughts of going there, but he soon abandoned Ireland for Scotland and France. The colony dwindled, and an Anglo-Irish parliament at Kilkenny in 1341, summoned without leave by the earl of Desmond, expressed its resentment against "the English by birth" who misgoverned Ireland, and complained of the decay of the revenue and the loss of a third of the land to the Irish. The capacity of this "middle nation," "Irish to the English and English to the Irish," to turn into temporary rebels was often to puzzle English rulers.

Finally a royal prince was sent, and Lionel, duke of Clarence (*see* CLARENCE, DUKES OF), ruled as viceroy for six years (1361–67). The Statutes of Kilkenny (1366) are the chief memorial of his rule. These enactments defined the "English" or "obedient" land as the counties and liberties of Louth, Meath, Trim, Dublin, Carlow, Kildare, Kilkenny, Wexford, Waterford and Tipperary. The decay of the colony was attributed to a general lapse into Irish language, law and usage, to intermarriage and fosterage and to the maintenance of Irish bards. Therefore the English were forbidden to make such alliances with the Irish or to use brehon law, and, along with the Irish who dwelt peaceably among them, were ordered to take English surnames, speak English and follow English law and custom.

The purpose of these statutes was to preserve as large an area as possible for England at the cost of abandoning the rest. The king's sovereignty over the whole island was not renounced, but the independent Irish were thenceforth treated as "Irish enemies," outside the pale (*q.v.*) of English law and loyalty and unable to plead in or profit by the civil courts, to marry or to purchase, possess or inherit land among the English. Up to the end of the 16th century the chiefs were held to have no right to their lands except by prescription and usurpation. But nothing could recall the "degenerate English" from friendly intercourse with the *meri Hibernici*, the native Irish. The old Gaelic civilization, badly shattered in the 13th century, recovered much of its strength in the 14th, and its music and poetry, the charm of its women, its ancient language and the aptness of its law laid an irresistible spell on the long-established settler families.

The marriage (1368) of Lionel's only daughter, Philippa, to Edmund Mortimer, 3rd earl of March and lord of Trim, carried to him the earldom of Ulster, and this great lord went to Ireland as viceroy in 1380, but died prematurely (*see* MORTIMER). Buying off the more powerful Irish chiefs by paying them "black rents" to keep the turbulent clans in order was now the poor device of

the colonists, whose most dreaded foe was Art Mac Murrough, king of Leinster. More than anything else, this chief's activities brought about the first royal visit since 1210. Richard II arrived at Waterford in Oct. 1394 with a large army, attended by Roger Mortimer and other peers, and stayed in Ireland till May 15, 1395. His general policy for the "Irish enemies" was to secure their homage and confirm them in such lands as they had not "usurped," but with one exception; Art Mac Murrough and his Leinster *urraghts* or vassals were to be induced to evacuate Leinster for other parts of Ireland and leave the province open to a new English plantation. This was achieved in both cases on paper; almost all the ruling chiefs, headed by Niall O'Neill, *Princeps Hibernicorum Ultonie*, came in and did liege homage and entered into indentures with the king. But on Richard's departure Mac Murrough refused to fulfill his extraordinary bargain. Roger Mortimer, 4th earl of March, left behind as viceroy, was slain by the Wicklow Irish in 1398, and Richard in fury hurried over to Ireland again in 1399. His armies could do nothing against the light-armed Irish in their forests, and the king returned to England.

There is little of importance to record of the dwindling "English land" during the Lancastrian period (1399–1461). An occasional strong viceroy, such as John Talbot, afterward 1st earl of Shrewsbury (*q.v.*), could do little against the "Irish enemy," the "degenerate English" and the "English by blood," who resented government from Westminster. A hope of uniting the Celts and the English was found in Edmund Mortimer, 5th earl of March and 7th earl of Ulster, who went to Ireland as viceroy and received the homage of O'Neill and other chiefs but died of the plague in 1425. The old English and the Gaels transferred their affections to his nephew, Richard, duke of York, and in the wars of succession in England were almost to a man for the White Rose.

The Rule of the Great Earls.—In reality three great earls then ruled Ireland. The greater part of counties Limerick, Cork, Kerry and Waterford with their towns had come under the absolute rule of the earls of Desmond; James "the White," 4th earl of Ormonde, had extended the power of the Butlers in Tipperary and Kilkenny; and the earls of Kildare were dominant in Leinster. The three families worked together, dominated the Dublin government in spite of an "English interest" headed by Talbot, took the lead of an Anglo-Irish home rule party and built up a rampart of feudal independence that later took the Tudors almost a century to break down.

"Aristocratic home rule" till 1495, and indeed till 1534, when Garret Og, 9th earl of Kildare, was finally detained in England, may be written over Anglo-Irish history. The Wars of the Roses were to the old English an occasion to secure colonial independence. Richard, duke of York, who became lord lieutenant in 1447 and was in Ireland from 1449 to 1450, played up to the enthusiasm that was at once displayed for his person and name. All Ireland believed him to be the true heir to the English crown and greeted with enthusiasm the hereditary claimant, who in return was expected to rule Ireland by Irish ideas. Hence, when he arrived as a defeated refugee in 1459, the Irish parliament greeted him almost as a king, but proceeded to declare that the land of Ireland was bound only by the statutes of its own estates. When his son Edward ascended the English throne (1461), Ireland seemed to have the king of its choice, and the earldom of Ulster was merged in the crown. James, 5th earl of Ormonde, taking the Lancastrian side, was executed (1461) after the battle of Towton, and his house attainted. His two brothers, successively earls, spent their lives in England, and a junior branch of the Butlers took practical possession of the Ormonde lands.

King Edward IV had little love for an oligarchy which ruled Ireland under the guise of Yorkist loyalty, and all Ireland was appalled when a new viceroy, John Tiptoft, earl of Worcester, got Thomas, earl of Desmond, attainted "for treasons alliances and fosterages with the Irish enemies" and had him beheaded (1468). But Edward was not in a position to go further; after this exhibition of bloodletting, the government had to be left to the Anglo-Irish, and Thomas, earl of Kildare, ruled as deputy till his death in 1477. Under his son, Gerald, called by the Irish "Garret More" (the Great), the Kildare supremacy reached an almost royal height. Although only deputy for English princes who bore the empty titles of lords lieutenant, Gerald was, in effect, actual ruler of Ireland. The old English were for him, his sister was wife to the Irish chief Conn O'Neill, various daughters of his married Irish chiefs, and the Dublin parliament was at his beck and call. He had the revenues of Ireland and the appointment to offices; these went to his supporters and Irishmen ruled Ireland. So things stood when Richard III fell at the battle of Bosworth Field (1485).

(E. Cu.; A. Gw.)

The Tudors

The Kildare Ascendancy.—The battle of Bosworth Field (Aug. 1485), which substituted Tudor for Yorkist rule in England, had no apparent effect in Ireland, where the ascendancy of the Fitzgerald earls of Kildare, established more than ten years previously, had passed (1477) from Thomas, 7th earl, created lord deputy in 1471, to his son Garret More (Great Gerald). The king's power continued to be exercised largely through dynastic alliances with the great Gaelic and Anglo-Irish lords of O'Neill in Ulster, MacWilliam Burke in Connaught and Fitzgerald of Desmond in the south. The junior branches of the Butlers in Leinster were dependent on Kildare, just as the senior branch, then absentees in England, were dependent on the king. Among the minor lords of the English pale some opposition to Kildare might occasionally be built up. A greater degree of independence showed itself in the towns, and those in the southeast relied upon their contact with England to assert themselves from time to time.

The fiction of the king's power was preserved by appointing an absentee lieutenant from whom the earls of Kildare held as deputy. But the deputies had inherited a tradition of independence from the preceding era in which Richard duke of York had ruled Ireland, though the authority of Henry VI was partly recognized. Edward IV had not broken this by his appointment of Worcester and the execution of Desmond. The southern Fitzgeralds thereafter withheld their allegiance and maintained their independence by foreign intrigues, thus imitating those in Ireland who had supported the Yorkists during the Lancastrian period. Nevertheless, when Kildare gave recognition and support to the pretender Lambert Simnel (*q.v.*), Henry VII proved sufficiently strong to check but not to displace him. The defeat of Simnel at the battle of Stoke (1487) confirmed the result of Bosworth Field and made it clear that an Irish army was no more likely to be successful in invading England in 1487 than in 1460, when Richard of York had made the bid for power which ended in his death at Wakefield. Although Kildare was too careful to recognize the next pretender, Perkin Warbeck, Henry VII in 1494 decided to remove him and attempt to rule through Sir Edward Poynings (*q.v.*). With this appointment a struggle began between the new English absolute national monarchy and the old style Ireland with its habits of qualified allegiance and of pride in independence.

Poynings was primarily a soldier but he was expected to be an administrator and a legislator. Within the English pale he succeeded, with the help of some of the Butlers of Ormonde, in driving the king's enemies from the field. He subdued Kildare but could not reconquer the Irish of the north, and he left the west and south alone. As an administrator he inaugurated reforms in the king's government, but at such a cost that Henry could not maintain them unless he was prepared, and he was not, to send annual subsidies from England. As a legislator, Poynings was able to secure, by the Statutes of Drogheda, better known as Poynings' law, the extension to Ireland of the public statutes of England and to provide for nullification of parliamentary proceedings in Ireland which had not previously been approved in England by the king and council. The importance of Poynings' work was not immediately recognizable, as Henry decided (1496) to restore Kildare and adopt the less ambitious policy of sealing off Ireland from his dynastic enemies by a matrimonial alliance. Kildare married Henry's cousin, Elizabeth St. John, and it was understood that he would accept the Poynings' legislation.

After 1496 Kildare continued to rule Ireland, extending his own power and weakening that of the other great lords, but observing his understanding with the Tudors. On his death (1513) the

deputyship passed to his son, Garret Og (Young Gerald), 9th earl of Kildare, who continued to dominate the country. Confronted by an English monarchy increasingly absolute and engaged in an increasingly dangerous foreign policy, Kildare was not as effective as his father had been in maintaining the peace in Ireland and he was temporarily replaced (1520–22) as viceroy by Thomas, earl of Surrey. After Kildare was restored, James, 10th earl of Desmond, intrigued with the emperor Charles V; Henry VIII thus became convinced that Kildare had lost the power to keep Ireland neutral, and when the divorce (1533) of Catherine of Aragon made the danger of imperial intervention particularly acute, the king decided on a new viceregal policy in Ireland and summoned Kildare to England (Feb. 1534). There were thereafter no Irish-born viceroys for more than a century.

The Reformation Period.—Rumours that Kildare had been executed precipitated the rebellion (June 1534) of Lord Thomas Fitzgerald (*q.v.*), called "Silken Thomas," which in a way facilitated the transition to the new system. Silken Thomas had raised the issue of the king's breach with Rome; his execution (1537) and the destruction of the Fitzgeralds caused a revival of the power of the Butlers of Ormonde and Piers Butler, earl of Ossory (1528–38), helped to secure the enactment of the royal supremacy by the Dublin parliament of 1536–37. As a further step in getting rid of the pope, a complaisant parliament recognized Henry VIII as king of Ireland (1541). Confiscation of monastic property, as well as of the lands of the rebels, provided the necessary capital to pay for most of the costs of the expanded administration. But it inaugurated the beginning of a new era in corruption by encouraging officials to fan the flames of revolt in the hopes of obtaining grants of the rebels' confiscated land.

Inevitably, this loss of land drove the religious orders and the Anglo-Irish into the arms of the Gaelic Irish, thus weakening the old racial rivalries of medieval Ireland. Against a persecuting English administration the Gaelic Irish were now to find sympathy among their erstwhile enemies, the Anglo-Irish, as well as among the religious who now no longer felt that 12th-century papal approval of the Norman conquest of Ireland obliged them to preach acquiescence in English rule.

Sir Anthony St. Leger (*q.v.*), lord deputy (1540–48, 1550–51, 1553–56), then began a conciliation policy by which outstanding lords were persuaded, in return for new titles and grants of land, to renounce the pope and recognize the king. Its success, however, depended upon a series of efficient governors and disciplined administrators, and to convert elective chiefs into hereditary nobles, to transfer their palatinate powers into offices delegated by the crown proved in the long run beyond the competence of the English sent to Ireland by the Tudors and the Stuarts. Moreover, the temptation to condemn for religious conservatism and by legal technicalities to deprive of their lands those who had recently submitted to Henry's omnicompetent state was not often resisted. The champions of the older ways among the Gaelic Irish and among the old English families thus found it easy to foster discontent. St. Leger's success was all the more remarkable because the first Jesuit mission to Ireland arrived in the north in 1542, with credentials from Rome addressed to O'Neill. Fear of royal displeasure probably encouraged the Irish to urge the papal envoys to depart; but it is equally clear that the extreme measures of St. Leger's successors merely provoked a reaction against the Dublin government in which the Anglo-Irish increasingly took part.

Under Edward VI (1547–53) the Dublin authorities carried out a forward policy in religion as well as in politics. Protestantism, however, got no support except from English officials, and serious defections followed, including that of George Dowdall, whom Henry VIII had appointed archbishop of Armagh and who then refused to condone the abolition of the Mass. In Ossory, Bishop John Bale provoked such hostility as a reformer that he went in fear of his life, and fled on the accession of Mary I (1553). The restoration of Catholicism under Mary revealed the strength of resentment in Ireland against Protestantism. However, there was no persecution and the few heretical officials were privately permitted to hold services in their own homes. As in England, the papal jurisdiction was restored, but otherwise the Tudor canons of authority were observed. The pope was induced to recognize the conversion of the Tudor Irish lordship into a kingdom. The laws restricting appeals to Rome, or petitioning for benefices without royal consent, were strictly enforced. And finally Mary gave statutory approval for the plantation of Leix, Offaly, and other Irish lordships of the central plain which were shired and called Queen's county and King's county in honour of Mary and of her husband Philip II of Spain. In all this her viceroy was Thomas Radcliffe, earl of Sussex (*q.v.*), lord deputy (1556–59), who was soon to restore the state's authority over the church as lord lieutenant (1559–66) for Elizabeth I.

The Elizabethan Settlement.—Foreign affairs determined the speed of the Elizabethan church settlement in Ireland as well as in England. The Acts of Supremacy and Uniformity (1560) were passed, but fear of driving the inhabitants of the pale into alliance with the Gaelic Irish and perhaps with the Spanish made the government lenient in enforcing their terms. Only five bishops appear to have been asked to take the oath of supremacy; of these two refused. Political affairs continued to receive the main attention of the administrators, so that the new Protestant church was wholly unequipped to resist the forces which the Counter-Reformation was shortly to launch against it. This was perhaps inevitable in an Ireland no more than superficially conformed to royal obedience; but the seriousness of the situation can be seen in the three great rebellions which took place in the course of the reign, those of Shane O'Neill (1559), of the Fitzgeralds of Desmond (1568–83) and of O'Neill (Tyrone) and O'Donnell (1594–1603).

Shane O'Neill.—The first of these rebellions, that of Shane O'Neill, fully exposed the weakness and later the folly of the government. O'Neill's father, Con Bacach (the Lame), having submitted in 1541, had been made earl of Tyrone, the succession rights of his illegitimate son Feardorchadh (Matthew) being recognized. Shane, a younger son, established his martial superiority in his father's old age and won the support of the greater part of the influential people of the lordship against Feardorchadh. He was elected O'Neill on his father's death (1559) and soon afterward Feardorchadh was killed. O'Neill then demanded recognition by the Dublin government according to the laws of primogeniture, as Feardorchadh had not been born in wedlock, and he insisted that neither of the latter's sons, Brian (d. 1562) and Hugh, had claims to the earldom or to the junior title of baron of Dungannon. The Dublin government was not prepared to yield but when O'Neill took the field could not defeat him. Faced with a possible combination against her Dublin administrators, Elizabeth invited O'Neill to London to negotiate (1561–62).

The queen was obviously taken by the personality of O'Neill, but the opportunity for a statesmanlike settlement was lost. Instead a hollow arrangement was made; O'Neill was to be "captain of Tyrone" and was encouraged to expel the Macdonnell (MacDonald or MacConnell) migrants from Scotland whose chief Sorley Boy Macdonnell (*q.v.*; Somhairle Buidhe) had successfully established himself in Antrim. Matters became worse after O'Neill's return (May 1562); the Dublin administration condoned underhand moves against him and he, having routed the Macdonnells as well as the loyal O'Donnells of the northwest, attempted to secure support from Mary, queen of Scots, and from Charles de Lorraine, cardinal of Lorraine. On the advice of Sir Henry Sidney (*q.v.*), lord deputy (1565), a firm policy with O'Neill was then adopted, but the government was saved from a serious situation only through the defeat of O'Neill by the O'Donnells and his murder (1567) by the Macdonnells.

By a sweeping act of attainder, passed by the Dublin parliament of 1569, the lands of the O'Neills and even of loyal Gaelic lords were declared forfeit. In a wave of enthusiasm for colonization, questionable adventurers like Sir Warham St. Leger, Sir Peter Carew, Walter Devereux, 1st earl of Essex, and Thomas Smith, son of the queen's secretary, were permitted to attempt substantial plantations in Munster, Leinster and Ulster. The folly of this policy was seen when, in defiance of the recent attainder which had declared the name extinguished, the O'Neills' election of Turloch Luineach as their chief was given constructive recognition by the government; Butlers and Munster Fitzgeralds also combined

forcibly to resist the Carew-St. Leger actions. The only gleam of statesmanship shown by Sidney in these years was that he managed to avoid a major combination against the government over its religious policy. The Butlers were induced to submit, the planters were given but a limited support and a partial return was made to the earlier policy of conciliating the Gaelic Irish by restoring some favour to Hugh, baron of Dungannon, and avoiding a head-on collision with Turloch Luineach. When the Ulster plantation plans of Smith and Essex could not be carried out against Irish resistance the queen wisely decided they should be dropped. The pardon of the Butlers pacified Leinster but in Munster the earl of Desmond's cousin James Fitzgerald (*q.v.*), called "Fitzmaurice," attempted to make the war one of religion. Wisdom dictated a lenient policy and Sir John Perrot (*q.v.*), president of Munster (1570–76), was permitted to pardon the rebels. Sidney was allowed temporarily to retire (1571) but Sir William Fitzwilliam, who succeeded him as lord deputy (1572–75), proved inefficient yet oversevere, so that Fitzmaurice fled (1575) to the European mainland for support for a Catholic crusade. He returned in July 1579 with papal approval but with negligible equipment.

The Desmond Wars.—Although neither Spain nor France supported Pope Gregory XIII's plan for a holy war in Ireland against Elizabeth, the government was extremely apprehensive. But the earls of Desmond and Kildare gave Fitzmaurice no support and he was surprised and killed (Aug. 1579). Fitzmaurice was perhaps a small military loss; his work as an idealist was largely done and it was his removal that perhaps induced Gerald Fitzgerald, 15th earl of Desmond (*q.v.*), to join the enterprise and assume its direction. As a military commander Desmond was wholly deficient; although his prestige may have won over many in south Munster, his mediocrity may well have influenced outstanding figures in the north and west to stay outside the movement. Meanwhile Lord Grey of Wilton, deputy from 1580 to 1582, and Lord Ormonde defeated the rebels and massacred (Nov. 1580) a force of Italians and Spaniards at Dún an Oir (Golden Fort), Smerwick, County Kerry, on the plea that, as papal soldiers, they had no international status.

The end of the Desmond rebellion gave the government the opportunity to confiscate more than 300,000 acres in Munster and initiate more stringent proceedings against Catholics. But the plantation was not a success. Persecution of Catholics was sporadic. The most deplorable case was the torturing and hanging in Dublin, in 1584, of Archbishop Dermot O'Hurley of Cashel, who was captured in the pale soon after his arrival from Rome. Such actions inevitably encouraged co-operation between Catholic missionaries and Irish rebels, and were carefully avoided by the government in time of war. A more statesmanlike attitude was displayed in regard to Connaught land titles. When Perrot was lord deputy (1584–88) the western landowners were induced to compound their state obligations. In theory, as successor to the earls of Ulster and lords of Connaught the queen was entitled to feudal as well as regalian dues. The composition was an evaluation and division among landowners of these obligations, and it was a step in the process of converting to English tenures a great part of the country where the rights of the crown had not previously been recognized and where the title of the possessors of the land was extremely dubious. Perrot was less successful in handling the 1585–86 parliament and once again the government's anti-Catholic program was defeated by the opposition. He was perhaps even more unfortunate in alienating Archbishop Adam Loftus by an unsuccessful plan to convert St. Patrick's cathedral, Dublin, into an Irish university. His enemies had him recalled as an intriguer with Philip II, but although he died in the Tower (Sept. 1592) his guilt is more than doubtful. The return of Fitzwilliam as lord deputy coincided with the descent of the Armada (1588). Fitzwilliam was subsequently accused of precipitating the Tyrone war by his ineffectiveness in dealing with corrupt and tyrannical officials, but, as in the case of Perrot, the evidence is not conclusive.

The Tyrone War.—The origins of the O'Neill war remain in doubt. Hugh Roe O'Donnell and Hugh, earl of Tyrone, inaugurated as the O'Neill in 1593, certainly resented the extension of the royal administrative system, but the religious issue was probably more important. For a generation, but from very small beginnings, exiled Catholics had been trained as missionaries in the continental colleges of the Counter-Reformation. Among those who returned to Ireland the majority considered that a temporal victory over Elizabeth was essential if Catholicism was to be saved. A few, indeed, thought otherwise and preferred because of traditional loyalty to England to work in the pale and eschew the political enterprise. Attacks on notable prelates like Edmund MacGauran the primate, killed (1593) despite the protection of Hugh Maguire, lord of Fermanagh, and of Hugh Roe O'Donnell, strengthened those who called for a holy war against Elizabeth. Again there was an appeal for Spanish aid.

The outbreak of hostilities in Ulster in 1594 was at first confined to the northwest, where O'Donnell and Maguire tried to drive out the English troops. The intervention of Hugh O'Neill was expected if not inevitable. Since the inauguration as the O'Neill of Turloch Luineach he had maintained himself precariously and with little support from Dublin. As baron of Dungannon he was regarded in Gaelic Ulster as the queen's O'Neill. His loyalty in the Desmond rebellion was rewarded with the re-creation in his favour of the earldom of Tyrone (1585) at the time of Perrot's parliament. Tyrone realized that the less able Turloch Luineach exercised as O'Neill far more influence in Ulster than his own title brought him; and when the old man died in 1595 Tyrone had himself inaugurated as O'Neill in the traditional manner. His participation with his brother-in-law O'Donnell proved decisive in the north and west and the English were routed both in Ulster and in Connaught. A more intimidating combination thus threatened Dublin than even in Shane O'Neill's time. Discontent in the pale because of arbitrary exactions and exclusion from offices assured O'Neill of much sympathy. It was said that he knew of Dublin castle decisions before they were known in the city. In Aug. 1598 the defeat and death of the queen's marshal, Sir Henry Bagnall, seriously intimidated the Dublin administration; they were, however, severely censured by the queen for whining to O'Neill for mercy. Resentful of O'Neill's alleged ingratitude, Elizabeth became impatient of negotiations with him, and finally sent Robert Devereux, earl of Essex, to Ireland (April 1599) to subdue him. But Essex lost his reputation by his inglorious progress through the country and by the celerity with which he returned to England (Sept. 1599) after a private conversation with O'Neill.

Before Charles Blount, Lord Mountjoy, arrived (Feb. 1600) to replace Essex, the Irish leaders had concluded negotiations with Pope Clement VIII and with Spain. The former was quite prepared to accord crusading indulgences to the Irish Catholic forces, but would neither permit the excommunication of the queen's Catholic supporters nor entrust his legatine authority to a Spanish subject, even though he agreed to appoint Mathew de Oviedo, a Spanish Franciscan, as archbishop of Dublin. The dwindling resources of Spain, moreover, precluded Philip III from affording more than a minute force under Juan del Aguila to aid the Irish rebels. Aguila occupied Kinsale, and was besieged (Nov. 1601) by Mountjoy and his president of Munster, Sir George Carew. O'Neill marched south to relieve Aguila but, although he could move without impediment across the country he could not win the support of the Anglo-Irish towns or of many of the Anglo-Irish of Munster. A rash attempt to surprise the English lines by night proved disastrous (Dec. 24, 1601). The Irish were defeated and the Spaniards surrendered. O'Donnell returned to Spain with Aguila to try to get more reinforcements. O'Neill held out in Ulster for over a year but submitted a few days after the queen's death.

Viewed generally, Elizabeth's Irish policy had the distinction of having reduced the country to obedience for the first time since the invasion of Henry II. But the cost was a serious one. The loyalty of the Irish was perennially strained over the religious issue, so that rebellion in 1641 was almost inevitable when England was embarrassed by the second Bishops' War in Scotland. Economically the towns and the countryside were seriously exploited by the new administrators and planters, while the queen's expenditure was substantially increased. The poverty of the crown, which was a serious factor in the 17th century conflict with parliament, was at

least in part due to commitments over Ireland. (R. D. Es.)

17TH AND 18TH CENTURIES

James I, 1603–25.—On the religious question the policy of James was a guarded toleration. The royal prerogative was still supreme, especially in Ireland, and a series of viceroys, such as Arthur, Lord Chichester (1604–15), exercised it in the interests of that large majority which it seemed then almost hopeless to convert. The opposition of the Catholic party, led by the lords of the pale and the lawyers, was constitutional and loyal; it was impossible to debar recusants from parliament, even if the oath of supremacy barred them from government, and in the older towns this party was so strong that until 1624 each one had a Catholic mayor. Could James and this moderate element have had their way all might have been well, but the Counter-Reformation spirit on one hand and the Puritan on the other made plain sailing difficult. The established church in Ireland was for strong measures, and, on the other hand, when James proposed a simple oath of allegiance for recusants, by which they should repudiate the supposed right of the papacy to depose heretic kings, two papal briefs in 1606 declared the proposed oath unlawful for Catholics.

The Plantation of Ulster.—Though the earls of Tyrone and Tyrconnell had been restored in 1603, their new position was full of difficulties; Ulster was now shireland, subject to sheriffs and garrisons hateful to its ancient lords, and Tyrone, involved in disputes with bishops, officials, grantees and his former vassals, complained that strong forces at Dublin were against him. The Anglo-Spanish peace of 1604 and the personal union of England and Scotland under James also changed the political scene to Tyrone's disadvantage. And so in Sept. 1607, along with Tyrconnell and nearly 100 more chiefs of the north, he left Ireland forever. The "flight of the earls" was a mortal blow to the Catholic interest and the old Gaelic tradition. Celtic Ulster was subsequently to become the most British of the provinces, and the lament over the "flight of the earls" in the *Annála Ríoghachta Éireann* (*The Annals of the Four Masters*) can be regarded as the swan song of the Gaelic world. When the *Annals* were published in 1636 the Gaelic writers were already falling silent; and by the 18th century only the Irish language, itself then little used by the gentry, remained as a visible memorial of a world that went back 2,000 years (*see* IRISH LITERATURE; *Late Period*).

A plantation of Ireland was then urged on the ground that, without a strong Protestant population, neither would the state be safe nor the state church have congregations. The earls and their adherents were found guilty of treason, and by legal processes six counties were declared escheated. By the final plan (1609) the escheated lands were divided between undertakers, servitors and natives. Undertakers, mainly English, were to lease only to English and Scottish tenants and to take the oath of supremacy. Servitors, mainly Scots, might take Irish tenants, but if so their rents to the crown were increased. Native Irish grantees were to pay quitrents twice as large as the undertakers, but need not take the oath. Of these a good number received grants of thousands of acres, and several junior branches of the O'Neills and Magennises, etc., survived as large landlords, though no longer as Irish chiefs. But the colonists entered upon the best lands, and the lesser ranks of Irish were reduced to the position of tenants at will, for Sir John Davies, the attorney general, found, by a most iniquitous decision, that they had had no freehold rights under their attainted lords. The town of Derry was given to the City of London, and the London companies received grants which gave them almost all that county.

The practical success of the plantation was great as land hunger in the Scottish lowlands and in the western counties of England created a ready supply of immigrants. For the first time a large part of Ireland was not merely owned by alien landlords but was tilled and farmed by Scottish and Protestant farmers. The Irish population was numerous in the mountainous parts, and its natural disaffection was kept alive by hopes that Tyrone or another would return.

The success of the Ulster plan led to plantations in north Wexford, Longford, Leitrim and elsewhere, where, though the natives were treated with more equity, again the object of the crown lawyers was to find that most of the Irish were not freeholders but tenants at will. The new English were dominant; adventurers and speculators such as Richard Boyle, earl of Cork, and other moneyed men displaced the old aristocracy; 39 new boroughs, carefully rigged, could be counted to offset the old towns, and several of the old Irish had become Protestant.

In the parliament of 1613–15, summoned by Chichester to ratify the Ulster plantation, the government engineered a small majority, partly through the new close boroughs, but the minority could claim that it spoke for 21 counties and 28 ancient boroughs in this first general representation of the kingdom. After failing to get its choice as speaker, the opposition petitioned the crown, and James saw a deputation of old English peers and commoners who complained of religion, the new boroughs and the rigging of elections. James is said to have thoroughly enjoyed himself and declared, "What if I had created 40 noblemen and 400 boroughs?—the more the merrier," and, as regards religion, "the pope is your father *in spiritualibus* and I *in temporalibus* only; you are but half-subjects and therefore only entitled to half privileges." The upshot was that 11 boroughs were disfranchised; James spoke some fair words and continued the laissez-faire policy on religion; and parliament voted a large subsidy. The recusants, though called "old English Irelandized," were, in fact, loyalists with a religious grievance, but they had their left wing, and this veered steadily toward armed protest. It was during these years that the Counter-Reformation made headway, especially in the towns. From 1618 onward a Roman Catholic hierarchy came into residence, eventually to emerge in 1642 into the full political daylight.

Charles I, 1625–49.—With the second Stuart came the idea of raising men and money in return for religious concessions. The deputy, Lord Falkland, was allowed to promise various concessions, known as "the graces," such as that Catholics might practise at the bar and that where land titles, like those of the Connaught gentry under the Composition of Connaught, were lacking in legal confirmation, 60 years' possession was to be held good against the crown. From agents of the Catholic party Falkland secured a pledge of subsidies amounting to £120,000. But when the agents reached London they found a strong antipapist spirit there, under pressure of which Charles gave way. He dropped "the graces" but exacted the subsidies, though no parliament was called to ratify them.

To make Ireland first prosperous and then to use it in the royal interest against Puritan opposition was the idea of Thomas Wentworth, later earl of Strafford, lord deputy from 1633 to 1640. He set himself to break the power of the great and the monopolists, making the court of Castle Chamber into a Star Chamber for Ireland. While he wrested power from the anti-Irish clique in Dublin, he had no sympathy with Irish or Catholic complaints and looked on religious concessions merely as policy. Similarly, his aim in making Ireland rich and prosperous was that out of a surplus revenue he might enrich his royal master, and the first-rate army that he raised largely from Catholics and natives was destined, if need be, to serve in Britain. Among his strongest measures were extracting subsidies of £50,000 from parliament and then denying all but the least important of "the graces"; forcing the juries of Connaught to find a title there for the king, with a view to a fresh plantation; and attacking the London companies. But the policy of "Thorough," as Strafford called it, ultimately failed and when he was assailed in England all the interests he had offended in Ireland joined in the general impeachment that brought him to the scaffold in May 1641. His army was disbanded and the control of the government passed under Puritan lords justices.

A rising in Ulster was almost inevitable. The Irish there had local leaders of the old stock, such as Sir Phelim O'Neill, and still more abroad, where Owen Roe O'Neill, nephew of Tyrone, was in Spanish service. In the south the native party found a leader in Rory O'More, who planned a union of the old English, with their religious grievances, and the Irish who had lost vast estates. A plot to seize Dublin castle failed, but the rising in Ulster was general (Oct. 1641) and thousands of colonists were murdered, died of ill-treatment or fled.

For the suppression of the Irish war the English parliament at once voted an army, but in order to find the money offered to the adventurers or subscribers of £1,000,000 the pledge of 2,500,000 ac. of profitable lands which were to be confiscated. Naturally, the dread of confiscation, coupled with a belief that the Puritans meant to extirpate their religion, drove more and more Irish to arms. A Catholic confederacy was formed at Kilkenny in May 1642 "to defend religion and the king against sectaries, and establish the Catholic religion as fully as at any time since Henry VII"; soon Richard Preston, earl of Desmond, and Owen Roe arrived from abroad, the first to lead the confederate armies, the second the Ulster forces.

The story of the next seven years is a complicated one. Though the confederation of Kilkenny organized a Catholic parliament and government, it did not succeed in welding together the parties of which it was composed. So while the Irish, whose chief figure was Owen Roe O'Neill, commanding an Ulster army, and the old English, supported by Preston, commanding a Leinster army, debated at Kilkenny, parliamentary armies operated in the north and south and Dublin was held by James, marquess of Ormonde, commanding an army of Protestant royalists. The confederation gained some recognition abroad, and in 1645 John Baptist Rinuccini, archbishop of Fermo, arrived as an accredited papal nuncio. Negotiations took place between Ormonde and the confederates which led first to a cessation of fighting and then to active peace proposals. It was hoped that Irish troops would eventually come to the aid of Charles. The negotiations were protracted because of religious issues and the future of the plantations. The first Ormonde peace was signed in 1646, only to be condemned almost immediately by Rinuccini and the Catholic hierarchy, whose position had been greatly strengthened by O'Neill's victory at Benburb in the same year. By that time the king's cause was already lost and Ormonde, preferring "to surrender Dublin to English rebels than to Irish ones," handed over the capital to Col. Michael Jones, the parliamentary commander, and left Ireland in 1647. During the second phase of the Civil War in 1648, new negotiations were opened which led to the signing of the second Ormonde peace in 1649. It was this which caused Rinuccini to leave Ireland. By then however the royalist cause was hopeless and the confederates in isolation were able to put up little resistance to Oliver Cromwell later in 1649. By 1652 all Irish resistance was over. (*See* also CIVIL WAR, ENGLISH.)

The Cromwellian Regime.—The detailed history of the Cromwellian land settlement itself has still to be written, though the general outlines are fairly clear. The Cromwellian government needed to provide more than 2,000,000 ac. of land to fulfill its debts. For this purpose, an act was passed in 1652 by the terms of which all Irishmen who could not prove themselves to have supported the Commonwealth were liable either to the death penalty, loss of property or both. Connacht was reserved for the "innocent"; the rest of the country was to be divided into an English pale from which the Irish were to be excluded. Ten or more counties were to meet the claims of the "adventurers" and the army and the remaining counties were to meet all other debts. Charles Fleetwood, commander in chief and lord deputy, was determined that the plans to transplant the population should be carried out. However, little resettlement had taken place by May 1654. A further attempt was made in 1655, backed up by force, including transportation to Barbados, but it proved impracticable. As a result, a change to a milder policy occurred and Henry Cromwell succeeded Fleetwood as deputy in Sept. 1655. Sir William Petty finished the Down survey in 1656 (so-called because it was the first survey to be put down on maps). By 1658 the claims of the army and the adventurers had been satisfied; a new landlord class had been created which was to remain for over two centuries.

While all this was happening, large numbers of soldiers left Ireland for the continent. The exiles also included clergy. Bitter disputes broke out among them, between the old English and the Ulster Irish as to which was responsible for the failure of the Confederation of Kilkenny. Rival historical accounts appeared, one by the Anglo-Irish Richard Bellings blaming the nuncio, others such as the *Aphorismical Discovery* criticizing the Machiavellian policies of Ormonde and his supporters. (H. F. KE.)

Charles II and James II.—With the Restoration, Ormonde, who had been raised to a dukedom, returned to Ireland as lord lieutenant in July 1662. Roman Catholics hoped to be rewarded for their support of the royalist cause, but Charles II, although acknowledging their help, also had obligations to those Cromwellian officers who had joined in inviting him back. Characteristically, Charles made promises to both: Cromwellians should keep what they had, Catholics should recover what they had lost. Ormonde's comment was that a new Ireland would have to be discovered. The Irish parliament passed the Act of Settlement (1662), embodying both promises and setting up a court of claims to select Catholics who were qualified to recover their lands. The act was unworkable, but the deadlock was broken by further legislation, the Act of Explanation (1665), which obliged Cromwellians generally to surrender one-third of their holdings to form a pool from which Catholics could be partially compensated. The Restoration settlement satisfied neither side. Cromwellians resented having to surrender part of their acquisitions; Catholics were discontented with the fraction they had recovered, particularly as policy and influence favoured the "old English" nobility at the expense of the native Irish and lesser claimants generally, most of whom recovered nothing.

In spite of English restrictions on cattle exports and colonial trade, Ireland's economy flourished in Charles II's reign. Catholics, excluded from public life, prospered in trade and commerce. For most of the reign their religion was tolerated in practice, although the "popish plot" scare resulted in a bout of persecution, a notable victim being the Roman Catholic archbishop, Oliver Plunket, who was executed in 1681.

A new situation arose with the accession of the Catholic James II in 1685. Ormonde was recalled and his successor, the king's brother-in-law the Protestant earl of Clarendon, was soon replaced by the Catholic earl of Tyrconnel (*see* TYRCONNEL, RICHARD TALBOT, Earl of). Protestants were purged from the army, the administration and the judiciary and Catholics appointed in their place. There was talk of "driving a coach and six through the Act of Settlement." Protestants became alarmed and an exodus to England began.

The Jacobite War, 1689–91.—When the Revolution of 1688 drove James from the throne of England, Tyrconnel continued to rule Ireland in his name. In March 1689 James crossed to Ireland from France and was welcomed by Catholics, largely because they expected him to restore their lands. Only Londonderry and Enniskillen—Protestant cities of refuge in the north—acknowledged William of Orange as king. James, with a realization of English opinion, was reluctant to interfere with the land settlement. But under pressure from his Catholic supporters he summoned a parliament in Dublin, the "patriot parliament," which repealed the Act of Settlement and passed an act of attainder subjecting some thousands of Protestants to the penalties of treason if they did not acknowledge James. These acts provided the basis for a wholesale retransfer of land from Protestants to Catholics, but their effectiveness depended on a Jacobite victory.

Londonderry withstood a siege of 105 days, during which the garrison was reduced to near-starvation. Enniskillen conducted a spirited and successful defense. James withdrew his forces from most of Ulster, leaving the way open for a Williamite army under the veteran marshal Friedrich, duke of Schomberg, who achieved little. In 1690 William himself came to Ireland with an international army. The battle of the Boyne on July 1, 1690, was of European significance as a gain for the Grand alliance in its struggle against Louis XIV, who supplied James with money, arms and 7,000 French troops (*see* GRAND ALLIANCE, WAR OF THE). But the Boyne was not an overwhelming military victory; the Jacobite army was scattered, not destroyed. It was, however, politically decisive. James returned to France, leaving William in control of Dublin and most of the country. The Irish Jacobites continued to fight, hoping to get terms that would secure their estates and obtain toleration for the Catholic religion. They found a leader in Patrick Sarsfield, who rebuffed William at Limerick and succeeded in prolonging the war until 1691, by which time William

had returned to England. William's Dutch general, Godard van Ginkel, afterward earl of Athlone (*q.v.*), who captured Athlone, won the decisive battle of Aughrim on July 12, 1691, and negotiated the surrender of Limerick.

The treaty of Limerick (Oct. 3, 1691), which brought the war to an end, consisted of two documents: the military and the civil articles. The former provided that those of the Irish army who wished should be transported to France and several thousand men under Sarsfield took advantage of these terms, forming the nucleus of the Irish regiments that earned distinction in the French service during the 18th century. The first of the civil articles promised the Roman Catholics of Ireland "such privileges in the exercise of their religion as are consistent with the laws of Ireland or as they did enjoy in the reign of Charles II." The phraseology was vague and it would be hard to say what privileges the laws of Ireland allowed to Catholics. But the terms of the article did not prepare Catholics for a multitude of fresh restrictions. The penal laws were specially resented as a breach of the treaty. The second civil article, which was kept in the main, promised pardon and restoration of lands to the garrison and inhabitants of Limerick and to other garrisons still holding out at the end of the war. Sarsfield stipulated that the terms should also cover all those under the protection of the Irish army in certain western counties. This clause was omitted from the signed copy of the articles, was restored by William, but finally omitted when the Irish Protestant parliament partially ratified the articles in 1697. This also was resented as a breach of faith, although the consequences seem to have been of little practical importance. The estates of those who were not protected by the treaty or by special pardon were confiscated, reducing Catholic holdings in Ireland from approximately 22% to 14%, a figure that was to be even further reduced in the course of the following century. William's generous grants from these estates to his Dutch supporters and in particular his grant of James's private estate to his mistress, Lady Orkney, incurred the censure of the English house of commons. He was forced to agree to an Act of Resumption (1700), by which his grants were cancelled and the estates sold as a contribution toward the expenses of the war in Ireland.

Protestant Ascendancy and Penal Laws.—The end of the war left the Protestants dominant politically, economically and socially, but they were apprehensive of a Stuart restoration and the revival of Catholic claims. They sought to secure their position by penal laws that imposed crippling restrictions on Catholics. Catholic bishops were banished and registration, together with the unpalatable oath of abjuration, was imposed on priests. A Catholic could not keep a school, be a guardian, carry arms without licence or own a horse worth £5. Catholics were prevented by law in 1704 from buying land; they could not lease it for more than 31 years and the rent payable had to be at least two thirds of the annual value of the property; estates of inheritance had to be partitioned among all a man's sons, by the system known as gavelkind, unless the eldest son conformed to the established church. A sacramental test, which excluded Presbyterians also, was imposed on holders of public office. Most Catholic landowning families conformed but the majority of Catholics remained faithful to their religion. Although Ireland was undisturbed by the Jacobite rebellions of 1715 and 1745, the penal laws bred deep resentment and their economic and social effects were disastrous for the country.

Protestants also had their grievances. England imposed commercial restrictions, notably the prohibition on the export of woolen goods to foreign countries. The English parliament claimed the right to legislate for Ireland, a claim specifically made in the Declaratory act (1719), and the English house of lords was the final court of appeal for Irish cases. More and more of the higher posts in church and state went to Englishmen. Irish rents were spent in England by absentee landlords. In consequence, a spirit of "colonial nationalism" grew up, fostered by such men as William Molyneux, whose *Case of Ireland's Being Bound . . .* (1698) opposed the legislative claims of the English parliament. Jonathan Swift's *Drapier's Letters* (1724)—a scathing indictment of William Wood's halfpence—succeeded in putting a stop to a bad piece of jobbery. Bishop George Berkeley's *The Querist* (1735–37) also drew attention to the misfortunes of the peasants and the evils of the system of landownership.

The Irish parliament was an unrepresentative body, exclusively Protestant in membership and in the main elected by small Protestant corporations; such Catholic electors as there were lost the franchise in 1727. Until 1768 the life of the Irish parliament was limited only by that of the monarch; its legislative program was strictly controlled by the English government through Poynings' law of 1494. It normally met for a few months every second year, when "undertakers" used their powers of patronage to get the money bills passed. (J. G. Si.)

Growth of Irish Parliamentary Opposition.—An active parliamentary opposition emerged in the Irish house of commons after 1750 and twice the government was seriously embarrassed. The duke of Dorset, as lord lieutenant, was faced with stiff opposition from 1753 to 1755 over the government's disposition of the revenue surplus, and Lord Townshend, viceroy from 1767 to 1772, experienced great difficulties with his augmentation bill. The American Revolution greatly influenced Irish politics; there were obvious analogies, political and constitutional, between Ireland and the rebellious colonies and from the outset there was considerable sympathy for them in Ireland, especially among the Presbyterians in the north. In 1778 a great shift occurred in the balance of power in Ireland. A large proportion of the forces maintained by Ireland had been sent overseas and, with a French war impending, it was clear the country was inadequately defended. The Irish Protestants promptly started to organize for defense. Volunteer corps were rapidly formed all over Ireland and soon far outnumbered the government's military forces. In 1779 Henry Grattan and Henry Flood (*qq.v.*) demanded free trade and their demand was reinforced by a volunteer demonstration in Dublin. The British government yielded in Dec. 1779; the restraints on Irish trade were swept away and Ireland was admitted to the colonial trade. But these concessions were too late to avert further demands. The delegates of the Ulster volunteer corps, meeting at Dungannon in Feb. 1782, demanded the repeal of the Declaratory act and Lord Rockingham's government hastily gave way. The Declaratory act was repealed and Poynings' law drastically amended so that bills which passed the Irish parliament were transmitted unaltered to England and, if they received the royal assent, returned to Ireland, under the English great seal. At the same time the custom of passing an annual mutiny bill was adopted and the Irish judges were given the same tenure of office as judges in England. This meant that they were no longer removable at the pleasure of the crown. There was a buoyant feeling in Ireland that the country was entering on a progressive and prosperous era and the growing consciousness of Ireland's nationhood, together with the liberal temper of the age, led to the abolition of many of the Catholic disabilities in 1778 and 1782, especially those affecting the exercise of religion and the possession of land.

After the constitutional changes of 1782 Ireland was theoretically an independent kingdom, sharing a common crown with Great Britain. But in practice the Irish executive was still controlled by the British government and by the use of patronage the Irish executive had considerable influence over the Irish parliament. In the winter of 1783 a volunteer convention in Dublin agreed on a plan of parliamentary reform which Flood immediately presented to the house of commons. The house of commons promptly rejected it and the leaders of the volunteers, men of property and standing, quietly accepted their defeat. The convention dissolved and the volunteer movement rapidly declined.

The Irish parliament made considerable efforts to promote the economic development of the country but the unsatisfactory nature of Anglo-Irish relations was soon shown by the debates over the commercial propositions and the regency crisis. In 1785 William Pitt introduced a plan providing for free trade between Great Britain and Ireland. The Irish house of commons accepted it; but at Westminster, under pressure from British industrial interests, several amendments were made, whereupon the Irish house rejected the entire plan. George III became insane in 1788 and a Whig ministry seemed probable in England. When the Irish parliament

met majorities in both houses rejected the government's plan of appointing a regent by act of parliament; instead, they proceeded to request the prince of Wales to assume the regency. Though the prince was in fact the regent designated by the British bill the implications of the Irish parliament's action were that it could appoint a different regent from Great Britain.

The influence of the French Revolution was soon felt in Ireland and both the Catholics and the radicals bestirred themselves in the early 1790s. The British government, faced by a major European war, was anxious to encourage Catholic loyalty and it forced the reluctant Irish administration to pass a comprehensive Relief act (1793) which granted Catholics the franchise, admission to the University of Dublin and to most civil offices. They were still debarred from parliament, from the highest posts in the public service and from the judicial bench. The government attempted to conciliate and influence Catholic opinion in 1795 by founding the seminary of Maynooth to provide, partly at the expense of the state, facilities for the education of the Catholic clergy.

Rebellion and Union.—The revival of Irish radicalism was signified by the publication of pamphlets by Theobald Wolfe Tone (*q.v.*), who strongly urged the Irish Catholics and radicals to form an alliance with the object of winning complete emancipation and parliamentary reform. Societies of United Irishmen—radical political clubs—were founded in Belfast, Dublin and elsewhere in 1791, advocating complete emancipation and a plan of parliamentary reform which included equal electoral districts and universal suffrage. The Dublin society, which vehemently supported these views, was suppressed in 1794.

It seemed likely, in 1794, that the Whig opposition would control the Irish administration. As a result of the coalition between Pitt and the "old Whigs," Lord Fitzwilliam was appointed lord lieutenant. The new viceroy made it clear that he was going to rely on the advice of the Irish Whigs and that he would support Catholic emancipation. His colleagues in England considered him to be impetuous and Fitzwilliam's recall after only six weeks in Ireland was a severe shock to moderate liberal opinion there. During 1795 an alliance between radicals and discontented sections of the working class brought a new association of United Irishmen into being; it was secret and organized on military lines and aimed at a radical reform of parliament and "a national government." Agrarian discontent was rife and many of the Irish peasantry who had formed secret societies of their own joined the new society. But in the north of Ireland agrarian strife took a sectarian form, the Catholic "defenders" clashing with the Protestant Peep-of-Day Boys, and the Orange society, founded in 1795, which was strongly conservative. A large French expedition sailed for Ireland in 1796 under the command of Gen. Lazare Hoche, together with Tone, who had gone to France at the beginning of the year to obtain help for the United Irishmen. Storms scattered the fleet and, though some ships reached Bantry bay, no troops were landed.

The Irish government, threatened by internal conspiracy and foreign invasion, displayed an unconciliatory determination, passing an Insurrection act in 1796 and suspending the Habeas Corpus act. During 1797 Gen. Gerard (afterward 1st Viscount) Lake confiscated private arms in the north and suppressed the *Northern Star*, the very lively radical newspaper published in Belfast. In the early months of 1798 the tension greatly increased; the United Irishmen were preparing for rebellion and the government was desperately trying to break their organization. The government managed to arrest a number of the radical leaders in the spring but in May the rising broke out. Only in east Ulster and Wexford was the rising widespread. The rebels in the north were defeated at Antrim and Ballinahinch; while the Wexford men defeated the government troops in some engagements but failed to take New Ross and Arklow. By the middle of June large forces of government troops under General Lake were concentrated in Wexford and the rebels were defeated at Vinegar Hill (June 21, 1798). The rebellion was almost over when a small French force landed near Killala; it won a victory at Castlebar but was soon surrounded and captured.

The rebellion brought the Irish question forcibly to the attention of the British cabinet, and Pitt decided that the best solution was a union. The Irish parliament was to be abolished, Ireland being henceforth represented at Westminster by 4 spiritual peers, 28 temporal peers and 100 members of parliament. A union, Pitt argued, would both strengthen the connection between the two countries and provide Ireland with opportunities for economic development. It would also, he thought, make it easier to grant concessions to the Catholics, since they would be a minority in a united kingdom. Naturally the union met with strong resistance in the Irish parliament but the government, by paying careful attention to the personal objectives of the members, and by providing generous compensation to the owners of boroughs which were being disfranchised, secured a majority which carried the union on Aug. 1, 1800. (R. B. McD.)

The Union (1800–1921)

Resistance to Pitt's campaign for a legislative union had been so strong in the Irish parliament that the measure was carried only by the undisguised purchase of votes, either by cash or by the bestowal of honours. But opposition to it among the landowners and the lawyers did not last long, and after a few years the agitation for a repeal of the union was being generally opposed, even by those who had protested vehemently against the extinction of the Irish parliament. On the other hand, the support for the union which Pitt and Castlereagh had gained from most of the leading Catholics was quickly lost. Bishop Francis Moylan and others had used their great influence on behalf of the union, in expectation that Pitt would redeem his promise to introduce Catholic emancipation at once by an act of the joint legislature in London. The Catholics had already gained important concessions since the establishment in 1795 of the Royal Catholic college at Maynooth as a national seminary for training Irish priests. They could no longer be educated in France and the Low Countries, since the Irish colleges there, which had kept the Catholic Church supplied with priests for generations, had been suppressed under the Revolutionary penal laws. The bishops had been appalled by the antireligious campaign in France, and they had also seen the Irish regiments of the French army disbanded, their officers enlisting in other armies to fight against revolutionary France. Pitt had not only endowed Maynooth but had given active help to the French clergy who escaped from imminent danger of death. He had promised to admit the Irish Catholics to full civic rights, which the ascendancy in Dublin had persistently denied to them; and they had little sentimental regard for the Irish parliament, which was determined to uphold Protestant domination.

But Pitt's failure to carry out his promises produced a sense of betrayal and humiliation and the Catholic Church had no further sympathy with the new experiment. Wolfe Tone's attempts to bring a French expeditionary force to assist a national uprising had been actively opposed by the Catholic bishops, who dreaded revolutionary ideas. But Robert Emmet's abortive rising in Dublin in 1803 (*see* Emmet, Robert), though it had much less chance of success and was little more than a local riot, had a stronger sentimental appeal. The promised emancipation of the Catholics had been withheld because the king considered that their admission to parliament would be a violation of his coronation oath. Pitt had resigned the premiership as a gesture of loyalty to his promises, but he soon returned to office and refused to raise the Catholic question again.

Economic Effects of Union.—While the hopes of the Irish Catholics had thus been defeated, the economic and social consequences of the union for Ireland were soon found to be disastrous. Dublin ceased to be the metropolis in which the landowners had their town houses and their lavish social life. Many activities that had been connected with the Irish parliament either ceased or languished when London became the political and social centre. The most gifted and most public-spirited members of the community who were still elected to parliament now had to spend most of their time in London, while those who were no longer legislators soon tended to become absentee landlords. Trade and industry declined rapidly, especially in Dublin, and the sudden increase of absenteeism had an unexpected effect upon Irish agriculture when prices rose abnormally during the Napoleonic Wars.

Ireland's population in 1800 was 4,500,000. Of these, fewer than 500,000 were Protestants and about 900,000 were dissenters, who were chiefly in the eastern half of Ulster. Almost all the landowning class was Protestant, and Catholics had not been allowed even to buy land until the recent relaxation of the penal laws. The great majority of the 3,150,000 Catholics were either labourers or tenant farmers who held their land on short leases without any security of tenure or protection against increase of rents if they improved their holdings. When the landlords became absentees, they left their estates in the hands of agents who had no social responsibility and were concerned only with extorting the utmost profit from the land. A swift rise of prices during the Napoleonic Wars made it more profitable to multiply the small holdings, by dividing the estates, and so increase the rent rolls.

With no alternative occupation the competition for small holdings was extremely keen, and the landlords were not required to provide farm buildings or even cottages. Any young labourer who could build a miserable hut for himself could therefore attain at once all that could be expected by any tenant farmer. While high prices continued, the subdivision of farms increased everywhere, with rents steadily rising and no outlay of capital on improvements. There was no inducement to delay marriage until later in life, and the population rose very rapidly with young marriages and large families. The standard of living was low. On smallholdings of less than ten acres it was scarcely possible to grow any crops other than potatoes, which provided the only food for a whole family throughout the year. Even milk and butter were luxuries seldom seen. Any small crops of grain had to be sold to pay rent and tithes which were exacted regularly; and the few cattle or pigs which could be kept on the little holdings were the chief source from which such payments had to be met.

Catholic Emancipation.—The Catholic peasantry and labourers, who formed the bulk of the population, suffered acutely when prices fell after the Napoleonic Wars. Dublin declined rapidly after the extinction of the Irish parliament, and many industries in all parts of the country decayed. But a new Catholic middle class was slowly emerging, since the mitigation of the penal laws. Education was no longer forbidden, and churches could be built without breach of the law. There were no Catholic secondary schools, however, and the merchants and others who had formerly sent their sons to school in France sent them to the few Catholic colleges which had been opened in England, since they found refuge there from the Revolution. Catholics were already admitted to Trinity college, Dublin, and they could become lawyers and doctors. The young barristers who had benefited from these new advantages became the most active leaders of the demand for full civic rights.

Among them was Daniel O'Connell (*q.v.*), who had been at school in Douai until the French Revolution and had completed his legal training in London. One of his uncles, Gen. Count Daniel O'Connell, had been the last colonel of the disbanded Irish brigade in France, and Daniel had been brought up in County Kerry by another uncle who had for years conducted a flourishing contraband trade with the continent but had become a loyal government supporter since the Revolution. Among the young Catholic barristers who infused new life into the Catholic committee, Daniel O'Connell soon displayed outstanding gifts of popular leadership and great courage in asserting the Catholic claims. He had imbibed the new doctrines of democracy and equality and also the nationalism which had spread since the French Revolution. His attempts to revive and broaden the agitation for Catholic rights brought him into collision with the authorities at Dublin castle, but he showed great skill in confining his agitation to strictly constitutional demands. By exploiting his legal rights as a defending counsel, he converted the law courts into a platform for political agitation.

Grattan had continued at Westminster to press for Catholic emancipation, but he and other Protestant reformers were prepared to make concessions which O'Connell as a fervent Catholic would not accept. Sympathy with the Catholic grievances was widespread in England, and by 1815, when O'Connell had created a really formidable popular agitation in Ireland, emancipation probably would have been carried in the house of commons if the Catholics had agreed to a government veto upon the appointment of Catholic bishops. But O'Connell objected so vehemently to any government interference with religious matters that he preferred to allow his agitation to collapse. His nationalism also was so intense that he regarded repeal of the union as being more important than Catholic emancipation, which he knew that an Irish parliament must concede. His defiant methods and his democratic claims aroused alarm among the Protestant landowners who had formerly resisted the union but now feared that an Irish parliament would be overwhelmed by a Catholic majority.

O'Connell's personal magnetism and his unrivalled success as an advocate had brought new energy to the popular movement. In 1823 he revived the Catholic agitation, with the help of some brilliant younger leaders, by forming a Catholic association which was financed by subscriptions of a penny a month. A concerted revolt against payment of tithes to the established Church of Ireland was developing widely, and the demand for emancipation assumed a wider aspect, with O'Connell as the national leader asserting the people's rights against an oppressive system. Although sympathy with the Catholic claims was then widespread in England, George IV refused to allow the question to be raised. In 1826 the peasantry in Waterford showed its independence by voting against the powerful Beresford family on its own domain. In 1828 O'Connell himself stood for Clare, as a Catholic who would not take his seat until the anti-Catholic oath was abolished. His triumphant election compelled the duke of Wellington and Sir Robert Peel to carry the Emancipation act of 1829, which admitted Catholics to parliament and to most public offices.

Demand for Repeal of the Union.—When the Whigs had obtained power in 1830, O'Connell attempted to agitate by similar methods of mass meetings and popular organization for repeal of the union. His efforts were defeated by vigorous repression, and for about ten years he gave the Whigs a chance to fulfil their promises of enlightened reforms. But the house of commons had neither the time nor the knowledge to attend to Irish problems, which required drastic remedies, and the ascendancy still controlled Dublin castle and kept Catholics out of almost every office. Property, as well as land, was still mainly in Protestant hands, and the Catholic population was more impoverished than ever, while its numbers continued to expand. By 1841 there were about 8,200,000 people in Ireland, and the increase had been chiefly in all the overcrowded and infertile counties of the west. Destitution had become so prevalent that landowners were already doing their utmost to encourage emigration and to reduce the number of holdings.

After a decade of disappointment O'Connell decided to revive the repeal agitation in 1840. It came to life swiftly when the Young Ireland leaders, Charles Gavan Duffy and Thomas Osborne Davis (*qq.v.*), founded the weekly newspaper the *Nation* and threw their energies into organizing monster meetings in all parts of Ireland. Action in parliament was disregarded, while the popular demonstrations assumed a more definite character. A climax was reached in Oct. 1843 when Peel mobilized troops and artillery to suppress the monster meeting arranged at Clontarf, outside Dublin. O'Connell and the principal leaders were tried for seditious conspiracy and imprisoned, but were soon released after an appeal to the house of lords. O'Connell's method of popular agitation within the law had proved unavailing, and his strength became broken by age and the disease which caused his death in 1847.

The Great Famine.—The younger leaders demanded a bolder policy of revolt, and open friction between O'Connell and the Young Ireland movement had developed before the country was suddenly confronted by national famine in 1846. The potato crop, which was as indispensable to the people as rice in India, failed everywhere as a result of the blight, which was still an unknown disease. In 1846 and 1847 the blight was more general and devastating, and, with typhus following upon famine, vast numbers died. Emigration became the sole hope of escape, and there was a catastrophic decline of population. Every little farm had to support a family, but without potatoes the people could not survive. Out of less than 700,000 holdings, about 300,000 were smaller

than 3 ac. and another 250,000 were between 3 and 15 ac. Attempts to relieve the universal distress were ineffective. Large supplies of maize (corn) were imported by the government and by charitable agencies, and many temporary programs of relief work were organized to provide employment. Subscriptions poured in from the United States and other countries. But emigration was the chief escape from death by starvation and pestilence, and the population, which had risen to about 8,500,000 by 1845, had fallen by 1851 to 6,550,000.

O'Connell's cautious policy after his release in 1844 had made the Young Ireland leaders restless, while the popular agitation died down. The great famine intensified their conviction that unless the union was repealed there could be no constructive improvement. There was then a much wider difference between the economic conditions and needs of the two countries, and Irish needs were overridden or ignored, even when famine was depopulating the country. Young Ireland demanded that the export of grain and cattle should be forbidden while the people starved, and that the state should finance new industries and railways to give employment. But these demands conflicted with the sacred principles of free trade and private enterprise, and the house of commons generally ascribed Irish misery to the results of political agitation. In desperation the Young Ireland leaders began preparations for an armed rising to achieve national government. They were encouraged by the bloodless revolution in Paris which overthrew Louis Philippe early in 1848. But the government forced a premature outbreak in August, and the leaders were either deported as convicts to Tasmania or escaped to the United States.

Rise of Fenianism.—For about 20 years after the great famine, political agitation was subdued, while emigration continued to reduce the population every year. The landowners had also suffered severely from inability to collect rents, and there was a wholesale transfer of estates to new owners. Their first concern was to reduce the number of smallholdings and to substitute grazing for tillage on larger, consolidated farms. Evictions were widespread, and cottages were burned down at once by the landlords to prevent other impoverished tenants from occupying them. The flow of emigrants to the United States was encouraged by invitations from relatives and friends who were already there. And in England, also, the new industrial cities and shipping centres attracted large settlements of hopeless and embittered exiles from Ireland. Among them, both in the United States and in England, the Fenian movement spread widely as a secret revolutionary society which aimed at securing Ireland's political freedom by exploiting every opportunity to injure English interests. Fenianism became a serious menace when it was reinforced by many Irish-Americans who had served on both sides in the American Civil War. W. E. Gladstone at last recognized the necessity for drastic Irish reforms, and in 1869 he disestablished the Protestant Church in Ireland. The next year he introduced the first Irish Land act which conceded the principles of secure tenure and compensation for improvements. In 1870 the Home Rule association was founded by Isaac Butt (*q.v.*), a prominent Unionist lawyer who had been converted by the famine experience to the necessity for Irish self-government.

A return of bad harvests in 1879, however, brought new fears of famine, and the Land league was founded by Michael Davitt (*q.v.*). The son of an evicted tenant, he had become a Fenian as a young labourer in England and had spent years in prison there. His Land league soon gathered wide support for its program of fixity of tenure, fair rents and free sale. A formidable agrarian agitation developed when Davitt was joined by Charles Stewart Parnell (*q.v.*), a young landowner and member of parliament in the Home Rule party, which soon elected him as its leader in place of Butt. Parnell and Joseph Bigger had adopted a new policy of persistent obstruction at Westminster to compel attention to Irish needs. Their skilful and determined tactics brought parliamentary business to a standstill and galvanized the new popular agitation in Ireland. Gladstone was forced to introduce his Land act of 1881, which made large concessions including the "three F's"—fixity of tenure, fair rent and free sale of the tenant's interest; and its new rent tribunals soon insisted upon wholesale reductions of rent.

The Fenian revolutionary movement in the United States and in England agreed to support Parnell's dynamic leadership of the Home Rule party, which then aimed at forcing either Liberals or Tories to concede national government. In 1886 Gladstone introduced a Home Rule bill, but it was defeated and the Liberal party was split. Parnell, however, had created such a formidable movement, with widespread support from the United States and in England, that he seemed likely to succeed, until he was suddenly involved in divorce proceedings brought by his colleague Captain William O'Shea. Gladstone then announced that his nonconformist followers would not co-operate further if Parnell retained the leadership, and in Ireland the Catholic Church also insisted on his retirement. But Parnell refused to resign, and his party was bitterly divided when he died in Oct. 1891, fighting vehemently as leader of the minority.

The Nationalist Revival.—Gladstone introduced his second Home Rule bill in 1893; the house of commons passed it by 301 to 267, but the lords rejected it by 419 to 41. It became evident that the lords would always resist home rule, and nationalist hopes were further discouraged by the party split. Ireland's population had declined to 4,700,000 by 1891, and emigration continued to reduce it. But a new phase of nationalist revival then began, with a cultural and economic program. There was a revival of the Irish language, led by Douglas Hyde, and the co-operative movement in agriculture, fostered by Sir Horace Plunkett, coincided with a movement for Irish industrial development and with a general policy of creating an Irish Ireland. Anti-English feeling and a concentration upon internal progress, without regard to Westminster, were fostered by the centenary of the 1798 rebellion and by the pro-Boer demonstrations during the South African War. A new party called Sinn Féin (Ourselves Alone) was founded in 1900 by Arthur Griffith (*q.v.*), who ridiculed dependence upon the British parliament and demanded that the Irish members cease to attend it and form a national council in Ireland.

Conservative Reforms.—Around the close of the century Arthur Balfour had initiated a new Tory policy, designed to "kill Home Rule by kindness," by introducing constructive reforms in Ireland. The Congested Districts board carried out a general improvement of the uneconomic smallholdings in the west. A new department of agriculture and technical instruction gave much practical aid under Plunkett's direction. The Local Government act of 1898 abolished the grand juries and entrusted local affairs to elected councils. In 1903 George Wyndham (*q.v.*), as Irish secretary, was enabled to carry the Land Purchase act. It offered generous inducements to the landlords to sell their estates to the Land commission, which was to collect terminable land annuities instead of rent. The response was immediate and overwhelming, and the Irish land question was settled at last by transferring ownership of the land to the occupying tenants on easy terms.

The Third Home Rule Bill.—In 1900 the two rival wings of the Nationalist party were at last reunited by consent, when John Dillon as leader of the larger section agreed to serve under the Parnellite John Redmond. But hopes of carrying Home Rule were still distant while the lords' veto remained, though the party continued to press for an Irish parliament, with increasing support in England and the dominions. The Liberals' triumph in 1906 revived hope, but it was soon disappointed by the meagre offer of an Irish councils bill, which was at once rejected. Other reforms, however, including the National University act of 1907, were obtained; and in 1909 Redmond seized his chance of demanding a Home Rule bill when Lloyd George's radical budget provoked a collision with the house of lords. H. H. Asquith promised Home Rule if the Nationalists would support his campaign against the lords, and in 1911 the passage of the Parliament act seemed to assure the eventual success of a Home Rule bill. Popular enthusiasm had revived after years of despondency; a new generation, free from the inhibitions of old grievances and already accustomed to the responsibilities of local government, looked forward to a new era of opportunity in public service and in scope for employment at home. Nearly all the most important positions in the civil service and industry and commerce were still largely reserved

for Englishmen or for members of the old Protestant ascendancy. Even in the professions advancement had usually been the reward of service to the Unionist party and to Dublin castle.

Redmond, however, had unexpectedly achieved the balance of power between the rival parties at Westminster which had been Parnell's ambition. The two elections of 1910 had each returned a Liberal ministry dependent upon Irish Nationalist support. But they had abolished the lords' veto, and Home Rule had become part of the Liberal and Labour programs in England. Under the Parliament act, the Home Rule bill of 1912 was apparently ensured of enactment after two years' delay if it passed the commons a second time during the same parliament.

Opposition in Ulster.—The Unionist party adopted unexpected methods to defeat its progress. Andrew Bonar Law replaced A. J. Balfour as its leader in 1911, and he gave full support to the threats of defying parliament by armed resistance in Ulster. Thousands of Ulstermen signed the Ulster covenant of resistance to Home Rule (1912) and Sir Edward Carson (*see* CARSON, EDWARD HENRY CARSON, Baron), as leader of the Ulster Unionists, announced that a provisional government would be formed there to defeat Home Rule. Both Carson and J. H. Campbell represented Dublin university at Westminster, but every other Irish constituency outside Ulster had returned a Nationalist, almost without an exception, for many years. Even in Ulster, 16 of the 33 members were Nationalists, and a by-election for Derry city in 1912 was won by a Home Ruler, so that the province had a majority against the union. The Ulster Unionists for some time proclaimed their intention of defeating Home Rule for all Ireland by defying its operation; but they gradually fell back on a demand for exclusion of all Ulster from its scope. Redmond's claim that there was "no Ulster question" implied that even among the Ulster members there was then a majority for Home Rule. But his claim hardened the Protestant and Unionist resistance in the heavily populated counties around Belfast. Down, Antrim, Armagh and Derry all contained large Unionist majorities and were predominantly Protestant or Presbyterian. Donegal, Cavan and Monaghan had strong Home Rule majorities, and Tyrone and Fermanagh each had a small total majority for Home Rule.

No serious consideration had been given to separate treatment for Ulster, but the Unionists claimed exclusion for the whole province. They organized the Ulster volunteer force, for which the veteran Field Marshal Lord Roberts chose Gen. George Richardson as commander in chief. Arms for the Ulster volunteers were soon imported in defiance of the law, while Bonar Law and most of the leading English Unionists gave full encouragement to Carson's whirlwind campaign inciting to disorder. At Westminster, Redmond had apparently won the political game by the accepted rules, but the Unionists were openly organizing defiance of parliament in Ulster. They were boasting of active sympathy among most of the serving officers in the army. Their boasts became formidable when all officers in the cavalry brigade at the Curragh, led by Gen. Hubert Gough, suddenly announced in March 1914 that they would resign if called upon to move into Ulster. Mobilization orders had not even been issued, but there had been raids on war office depots in Ulster and reinforcements were needed, before Carson achieved a spectacular success in landing a large cargo of arms from Germany at Larne on April 24, 1914. The Curragh mutiny was followed by the resignation of Col. J. E. B. Seely as war minister, and Asquith personally assumed control.

SIGNING OF THE ULSTER COVENANT OF RESISTANCE TO HOME RULE IN BELFAST, SEPT. 28, 1912

(Front row from left to right) the marquis of Londonderry, Sir Edward Carson (signing) and Captain James Craig, later Lord Craigavon, first prime minister of Northern Ireland

The Irish Volunteers.—Before these sensational incidents, the Ulster volunteer movement had provoked inevitable countermeasures among the Nationalists. Faith in the efficacy of parliament had been rudely shaken by Carson's successful defiance. The younger Nationalists, especially in Ulster, considered Carson's aggressive realism more effective than Redmond's patient negotiations. In Nov. 1913 the Irish volunteers were launched in Dublin, to counteract the Ulster volunteers. They spread swiftly, especially in Ulster, and still more after the Curragh episode in March. Redmond was convinced that the Home Rule bill would become law that autumn and that only a European war could delay its operation. But the threats of civil war in Ulster were reinforced by large cargoes of imported rifles, and the British army's readiness to enforce order in Ulster was seriously in doubt. The Irish volunteers were gaining such support among the younger Nationalists that Redmond found it necessary to assume control of an unconstitutional movement which he instinctively distrusted. In May 1914 the Irish volunteers agreed to expand their former provisional committee, which consisted mostly of unknown men, into a larger directorate composed chiefly of Redmond's supporters.

By the early summer Ireland was thus confronted with the prospect of civil war, while the rival volunteer forces collected arms wherever they could. The outlook was so menacing that in July the king convened a conference of leaders on both sides at Buckingham palace to find an agreed solution. Carson's earlier efforts to prevent an Irish parliament were then reduced to demanding exclusion of Ulster, and the issue had been narrowed to a definition of the area for exclusion. Redmond had agreed reluctantly to a strictly temporary exclusion of those counties which had Unionist majorities. He would not concede Tyrone or Fermanagh or Derry city, and he insisted on exclusion only for a short period. After several days the conference reached a deadlock and reported its failure to agree.

Meanwhile a small cargo of arms for the Irish volunteers had been bought in Belgium and was brought secretly into Dublin bay at Howth on July 26. A parade of Irish volunteers unloaded the cargo but was challenged by military and police on returning to Dublin. An armed collision on the Dublin quays resulted in many civilian casualties. The Ulster volunteers had run their cargo at Larne with impunity, and this discrimination against the Nationalists aroused fierce popular resentment. Redmond obtained the adjournment of the house of commons in protest, but events swiftly eclipsed the crisis in Ireland when the Germans invaded Belgium on Aug. 3.

World War I.—When Sir Edward Grey announced the declaration of war, Redmond intervened to promise full Irish sympathy. He made an immediate offer that the Irish volunteers of both forces (renamed the national volunteers) would defend the coasts of Ireland and that all troops could be withdrawn. Soon afterward he undertook an open campaign to encourage recruiting for the Irish regiments in the British army. Great numbers of young Irishmen enlisted rapidly, and three new Irish divisions were recruited, one of them in Ulster. But Redmond's assurances that the Irish recruits would serve together soon led to bitter disappointment. Lord Kitchener, who had become war minister, had a deep distrust for Irish regiments, and he refused even a distinctive flag to the southern Irish divisions, though the Ulster division was allowed even to elect its own officers. Redmond's protests were unavailing, and the first enthusiasm for war service was soon deadened by official discouragement. But the flow of recruits continued steadily until it was computed that more than 200,000 had gone from Ireland without any measure of conscription.

Kitchener's attitude had also stimulated the more extreme Nationalist wing of the Irish volunteers, who had protested against Redmond's recruiting campaign, and they seceded as a separate force. Military repression, by censorship and by prosecutions for alleged seditious behaviour, soon increased disaffection. The original organizers of the Irish volunteers had consisted largely of recent recruits to the old Fenian Irish Republican brotherhood (I.R.B.), which had been lately revived in the United States. The Irish Republican brotherhood had discerned new prospects of

anti-English intervention in case of war in Europe, and Carson's successful defiance of parliament had stimulated anti-English feeling in the United States. The supreme council of the Irish Republican brotherhood had decided, immediately after war broke out, that the long-delayed opportunity for an armed rising in Ireland must now be seized. Steps were taken to solicit help from Germany, and arrangements were made for regular secret instructions to Ireland from the United States. Membership of the secret Irish Republican brotherhood was very restricted, and its influence was not recognized until long afterward. Before the end of 1914 full plans had already been made for the revolutionary outbreak which took the country by surprise on Easter Monday, 1916.

Redmond's national volunteers were then almost moribund, because the more active members had either gone to war service or seceded. The republican Irish volunteers, more active though less numerous, had been drilling intensively with a view to serious action. They were ostensibly led by Eoin (John) MacNeill, though the I.R.B., which had planned an insurrection, kept him in ignorance. The I.R.B. had been in touch with Sir Roger Casement (*q.v.*) during his futile mission to Germany and knew that he had obtained only a small cargo of obsolete arms. Before Casement was arrested in County Kerry after landing from a German submarine on April 21, 1916, and the German arms ship was sunk at sea, they had planned to rise on Easter Sunday, April 23. But MacNeill forestalled them by cancelling all mobilization orders, and only about 2,000 out of the small total force available were actually engaged on Easter Monday, when the general post office and other parts of Dublin were suddenly seized. For a week Dublin was paralyzed by street fighting until bombardment or fires compelled Patrick Pearse (*q.v.*) and his colleagues to surrender.

Asquith went at once to Ireland for a short visit, and announced openly that the former system of government there had completely broken down and a new departure was necessary. Lloyd George was appointed to attempt a final settlement by negotiating with both Irish parties. Each interpreted his offer differently and agreed to temporary concessions which were repudiated when the truth became clear. Redmond had persuaded the Ulster Nationalists to accept exclusion for six counties for six years only, while Carson had surrendered his claim to the three western counties of Ulster on condition that the rest got permanent exclusion. Bitter feeling had been aroused by the prolonged succession of executions and the deportation of a great number of political suspects. Redmond had vainly insisted that only a few exemplary sentences should be imposed, for what he described as an un-Irish conspiracy, inspired and financed by Germany. Lloyd George's part in the negotiations only strengthened the growing sense of betrayal, while the Home Rule act was still in abeyance. Sinn Féin candidates were put forward at by-elections and received overwhelming support. Popular sympathy with Sinn Féin was immensely increased by Lloyd George's decision to apply conscription to Ireland early in 1918. A general surge of protest was supported by a resolution from the Irish bishops at Maynooth, who denounced conscription in Ireland as being morally unjust. When this protest prevailed, Sinn Féin gathered momentum everywhere. At the elections in Dec. 1918 it captured almost every seat which had formerly been held by Redmond's party.

THE RUINS OF THE DUBLIN GENERAL POST OFFICE, AFTER IT WAS SHELLED DURING THE EASTER RISING, 1916

The Growth of Republicanism.—Irish influence in the United States had grown steadily since the great famine, and bitter memories still inspired anti-English sentiment even during the war. The Nationalist revival in Ireland was being harshly repressed, and, though the Home Rule bill had been enacted late in 1914, a suspensory act delayed its operation till the war ended. In a fast-changing world, Asquith's act seemed utterly inadequate. Sinn Féin was demanding an independent republic, claiming the right of national self-determination which Pres. Woodrow Wilson asserted to be the Allied war aim. Increasing pressure from the United States compelled Lloyd George to make new efforts; but the Irish convention which he appointed in 1917 to frame an Irish constitution by consent contained no representation of Sinn Féin. Many of the new members elected at the end of 1918 were then in prison for political agitation, and the Irish-Americans soon organized support for Ireland's representation at the peace conference at Versailles.

Agitation in Ireland intensified, and the Irish volunteers began to conduct guerrilla war against the military and armed police. As the Irish Republican army (I.R.A.) they soon engaged in widespread ambushes and attacks on barracks and convoys, and the government retaliated with ruthless reprisals. A large proportion of the Irish police resigned, and they were replaced by recruits from England, who became known as the Black and Tans, from their temporary uniforms. A new force of auxiliary police, recruited wholly from demobilized officers who lacked other employment, was organized under Gen. Hugh Tudor. They undertook a campaign of reprisals, culminating in setting fire to a large part of Cork, after similar outbursts in Balbriggan and other towns.

This open competition in violence soon brought deep discredit upon British rule, and a wave of protest arose in England, as well as in the United States and the dominions. The *Times* of London joined vigorously in denouncing the excesses of the crown forces and put forward a constructive solution in proposing dominion status for a new Irish parliament. Lloyd George made yet another attempt by carrying the Government of Ireland act of 1920, which was to establish two Irish parliaments, with equal though very limited powers, one for southern Ireland and one for the six counties of northern Ireland. There was to be a joint council representing both Irish governments, which was to propose future extensions of independent authority when opportunity arose. But Sinn Féin refused to bring the southern parliament into operation, though it contested the elections and won 73 of the 102 Irish constituencies, including every seat outside Ulster except the four allotted to Dublin university. The Northern Ireland parliament was brought into being, though the Ulster Unionists protested that they preferred to remain within the union. King George V went to Belfast and formally opened the new parliament on June 22, 1921. He had been deeply concerned over the chaos in Ireland, and his speech contained a deliberate appeal for reconciliation. Gen. Jan C. Smuts and other dominion statesmen had been urging a settlement on the lines of offering dominion status and had gained the king's support. Within a week Lloyd George offered a truce to Eamon de Valera (*q.v.*) as the Sinn Féin leader and invited ne-

gotiations which were soon opened and resulted in the Anglo-Irish treaty of Dec. 1921. For the subsequent history of Ireland, *see* IRELAND, REPUBLIC OF: *History;* IRELAND, NORTHERN: *History.* *See* also references under "Ireland" in the Index. (D. G.)

IRELAND, CHURCH OF. The Church of Ireland (embracing both the Republic of Ireland and Northern Ireland), in communion with the Anglican Church, traces its episcopal succession from the pre-Reformation church in Ireland. The beginnings of Christianity in Ireland are difficult to establish but it is more than likely that contact with the western shores of Britain had led to considerable evangelization before the coming of Patrick (*c.* 432), the patron saint of the country. The facts of the life of Patrick himself are not readily separable from the legend that surrounds them and it is likely that much that has been attributed to him was the work of other men. Undoubtedly, however, someone of the name came to be the "bishop of the Irish people." (*See* PATRICK, SAINT.)

Early Church.—The early church was monastic, without parochial or diocesan divisions or central government. What authority there was lay in the hands of the abbots, and the powers of bishops were limited to their purely spiritual functions. At a very early date the monasteries became centres of learning with a reputation extending far outside Ireland. Latin, doctrinal and moral theology and the Bible were chiefly studied, and a high standard in craftsmanship was attained. Many examples exist of the work of the monks in leather and precious metals; and their illuminating of manuscripts, particularly copies of the Scriptures, culminated in such masterpieces of the art as the Book of Durrow and the Book of Kells. The most celebrated of the monastic schools were those at Clonard, County Meath (founded by Finnian); Bangor, County Down (Comgall); Moville, County Down (Finnian of Moville); and Clonfert, County Galway (Brendan). (*See* also CELTIC CHURCH.)

The influence of these monasteries upon Britain and the continent of Europe from the latter part of the 6th century onward is attributable not only to their reputation as teaching centres but to the fact that from time to time companies of monks detached themselves to wander in search of places in which to practise their ascetic rule. It was this "wandering for the love of Christ" rather than any conventional missionary zeal that took Irish monks not

only to Britain but deep into Europe, probably to Iceland and possibly, even, to the coast of North America. Of these *peregrini* St. Columba and St. Columban (*qq.v.*) are typical as well as probably the most influential.

Columba, who was of royal blood, studied under the two Finnians at Moville and Clonard and later himself established monasteries in a number of places including Durrow, County Offaly. About 563 he left Ireland with 12 companions and settled on the island of Iona (*q.v.*), off the western coast of Scotland. There he established a monastery which was to become the base for the conversion of a large part of Scotland and, eventually, of northern England.

Columban went, about 590, by way of Britain to Gaul, where he settled in Annegray in the Vosges mountains. Later he built a permanent monastery at Luxeuil. A man of strong personality, he quarreled with the French bishops, withdrew to Switzerland and subsequently to Italy, where he died at his monastery of Bobbio. Other Irish monks who made their mark on the continent were Gall in Switzerland, Fergal in Austria, Disibod in Germany and Fursey in France. This missionary activity by Irish monks was most intensive during the 7th century but continued for the succeeding two or three centuries. During this latter period the work of Johannes Scotus Erigena, theologian and philosopher, and Dicuil, a geographer who described journeys by Irishmen to Egypt and Iceland, is notable.

The Irish church was proud of its independence of Rome and clung firmly to its own usages in preference to those adopted by the rest of Christendom. Its method of calculating the date of Easter was maintained in face of protests from advocates of the Roman calendar until 704. Even after this the Irish church did not submit to any real jurisdiction from Rome (as in the appointment of bishops and archbishops) until the 12th century.

The Norse invasions, beginning at the close of the 8th century, precipitated a decay of culture and learning in Ireland. Many of the old monasteries had fallen into secular hands, and about the middle of the 12th century St. Malachy (*q.v.*), friend of St. Bernard, introduced a new monastic system based on that of the Cistercians. The weakness of an unco-ordinated ecclesiastical organization became evident, and the influence of Rome, through Canterbury, began to be felt for the first time. English bishops, chief among them Gilbert of Limerick, possessed themselves of the most important sees. About 1110 Gilbert held a synod at Rathbreasail which divided Ireland into 25 sees subject to the primacy of Armagh. Subsequently the pope sent legates to assist at the bringing of the Irish church into conformity with the rest of western Christendom, and the synod of Kells (1152) created four provinces with Armagh, Dublin, Cashel and Tuam as archbishoprics. The final step in the process of reform was taken at the synod of Cashel (1171–72), when obedience to Rome was accepted. There, also, regulations were made for baptism and marriage, tithes and papal tribute. The native liturgies were abandoned and the usage of the English church was adopted.

The medieval history of the church in Ireland follows that of the country as a whole. Most of the country was only at intervals made conscious of English overlordship, and the tribal kings continued to wield authority. In the church, Englishmen were appointed to the more important positions, the native orders were gradually replaced from abroad, but most of the secular clergy were Irish and retained something of the old Celtic spirit. It is possible that had this remnant of independence been considered and fostered at the Reformation the Church of Ireland might have become the church of the majority. In the event, a quite different course was followed. The native Irish were antagonized and came to look on the attempt at reformation as a political expedient and a weapon of conquest (*see* IRELAND: *History*).

Reformation.—The Reformation period began with the passing in 1537 of the Irish Supremacy act, which asserted the English king's supremacy in the Irish as in the English church. But it was a very superficial Reformation: the dissolution of the monasteries was only partial, and scant knowledge of English meant that liturgical changes were few. No attempt was made to win the mass of the Irish people to Reformation principles, nor were the differences of religious outlook of succeeding English sovereigns brought home to the Irish as they were to the people of England. At Mary I's accession five bishops either abandoned or were deprived of their sees; but the Anglo-Irish who remained faithful to the Reformation were not subjected to persecution such as would have been their fate on the other side of the Irish sea. Again, under Elizabeth I, although two bishops were deprived for open resistance to the new order of things and stern measures were taken to suppress treasonable plotting against the constitution, the uniform policy of the government in ecclesiastical matters was one of toleration. James I caused the Supremacy act to be rigorously enforced, but on political rather than religious grounds. Charles I sold concessions to Irish Roman Catholics, taking little interest in the progress of Irish Protestantism. The earl of Strafford, however, inaugurated a period of rigorous high Anglicanism, to be followed, under Cromwell, by strictness in the opposite direction, but still toward the strengthening of English rule. In this period James Ussher, appointed archbishop of Armagh in 1625, stands out for successfully defending the independent character of the Irish church against the reforms of William Laud, archbishop of Canterbury. (*See* USSHER, JAMES.)

On the accession of Charles II, the church was strengthened by the translation of John Bramhall (the most learned and zealous of the prelates) from Derry to the primatial see of Armagh and by the consecration of 12 other bishops, among whom was Jeremy Taylor (*q.v.*). In 1658, largely through the work of William Bedell, bishop of Kilmore, the Bible had been printed for the first time in the Irish language, an event that fell just a century too late.

The stricter penal code introduced by the English government (1702–15) made the church more unpopular. The English government for political reasons tended to choose Englishmen for many Irish bishoprics, and the consequent involvement of higher clergy in state affairs proved very weakening to the church. In 1703, at the request of the clergy, the Irish convocation met after a 37-year interval and tabled many necessary reforms. To William King, bishop of Derry and subsequently archbishop of Dublin, was mainly attributable the reorganization of the work of the church, and the impulse he gave it was felt all through the 18th century. This was also the period of Jonathan Swift and George Berkeley. The later 18th century saw the Irish parliament asserting its independence, and at the same time there arose an atmosphere of reform within the church, stimulated by new pride in its missionary heritage and by a rising evangelical movement. Schools and charitable institutions were founded. Roman Catholics and Presbyterians alike received more tolerant treatment, but the privileged position of the Church of Ireland minority remained a grievance. The Church of Ireland perhaps for the first time began to take its place as an independent national church, but, once again, political considerations were to hinder development.

Disestablishment.—The Act of Union of 1800 was passed as a remedy for the disaffection that had culminated in the rebellion of 1798. By it the parliaments of England and Ireland were united and the church became a part of the United Church of England and Ireland. But the dissatisfaction felt by the majority of Irishmen because of the continued existence of the established church in a privileged position became increasingly plain as the years passed. Discontent was increased by the fact that the church drew its tithes largely from Roman Catholic tenant farmers. In the 1830s the agitation against this privilege became strong enough to be known as the tithe war. The census of 1861 showed that less than one-eighth of the population belonged to the established church, four-fifths being Roman Catholics. Once this was made clear, the passing of the Act of Disestablishment was only a question of time. Introduced by William Gladstone and passed in 1869, it became law on Jan. 1, 1871.

The church was thus suddenly thrown on its own resources and called on to reorganize its ecclesiastical system as well as to make provision for its future clergy. The spirit of the church of that time is shown by the fact that in 1865, with disestablishment imminent, the foundation stone was laid in Cork for an elaborate cathedral for that diocese. Many other cathedrals and churches were restored during the 20 years following the passing of the act.

Polity and Worship.—A convention of the bishops, clergy and laity was summoned in 1870, and its first act was to declare the adherence of the Church of Ireland to the ancient standards and its determination to uphold the doctrine and discipline of the Catholic and Apostolic Church, while reaffirming its witness, as Protestant and Reformed, against the innovations of Rome. Under the constitution then agreed on, the supreme governing body of the church is the general synod, consisting of the bishops and 208 clerical and 416 lay representatives of the several dioceses, whose local affairs are managed by diocesan synods. There are two primatial sees, Armagh and Dublin. Under the 1959 legislation diocesan bishops are elected by an electoral college representative of all dioceses of the province in which the vacancy has occurred. Failing such election, appointment passes to the house of bishops. Private patronage of benefices is almost nonexistent, and appointments are made by boards of nomination composed of diocesan and parochial nominators under the chairmanship of the bishop.

The Book of Common Prayer was twice revised after 1662—in 1878 and in 1924–26. Changes were slight, but criticism was directed against the "Constitutions and Canons Ecclesiastical" by which are forbidden the placing of the cross on the altar, the making of the sign of the cross by clergy or laity (except where ordered in the baptismal office) and bowing to the altar. There is a high degree of uniformity in ceremonial throughout the church.

The finances are controlled by the Representative Church body, to which a sum sufficient to provide life annuities for the then existing clergy (2,043 in number) was handed over by the Church Temporalities commissioners in 1870, together with £500,000 in compensation for private endowments. The annuities provided were subsequently commuted for a capital sum. So skilfully was this fund administered, and so generous were the contributions of clergy and laity, that the total assets of the Representative body amounted in 1960 to almost £14,000,000. Church of Ireland membership was approximately 500,000, or less than one-eighth the combined population of the republic and Northern Ireland.

IRELAND, NORTHERN, the six northeastern counties of Ireland, enjoying a measure of self-government within the United Kingdom of Great Britain and Northern Ireland. Established by the partition of the island following the Government of Ireland act of 1920, Northern Ireland comprises the counties of Antrim, Armagh, Down, Fermanagh, Londonderry and Tyrone, together with the county boroughs of Londonderry and Belfast, the capital city and seat of government. The area is 5,459 sq.mi., or about one-sixth of the whole island, but the population, 1,425,462 in 1961, is nearly one-third of the total. The population density (260 per sq.mi.), while little more than one-third that of England and Wales, greatly exceeds that of the Irish republic and reflects a more industrialized economy. The frontier with the Republic of Ireland, "the border," is about 250 mi. long, following a tortuous course across the Caledonian grain of the landscape. The seacoast, in many places rocky and picturesque, forms the boundary on the north and east from Lough Foyle to Carlingford Lough, both of which have long been points of entry, far outstripped in importance, however, by Belfast Lough. Northern Ireland contains all the counties of the historic province of Ulster (*q.v.*) except Cavan, Donegal and Monaghan and is often referred to as Ulster. Most of the province was colonized during the plantations of the early 17th century, and Scots settlers in particular, continuing to move in during the 18th century, have contributed to the character of this part of Ireland. The physical geography, geology, people, archaeology and history up till 1921 are described in the article IRELAND. (X.)

HISTORY

The first parliament of Northern Ireland was opened by King George V on June 22, 1921, the first prime minister being Sir James Craig (*see* CRAIGAVON, JAMES CRAIG, 1st Viscount), who took office at the head of a Unionist government, which had to deal with a disturbed country, troubled by bombings, shootings and incendiarism. From the close of 1921 there was civil war in the Irish Free State, and this overflowed into Northern Ireland, making the years 1922 and 1923 very turbulent. During 1922, in the course of these disturbances, 232 persons were killed in Northern Ireland, including two Unionist members of parliament, and nearly 1,000 were wounded. Extensive damage was done to property.

In accordance with the agreement which the United Kingdom government had made with the Free State, a boundary commission was established to investigate possible frontier changes between the Free State and Northern Ireland. The commission failed to agree and presented no report; negotiations were then opened between the governments concerned. A tripartite agreement was signed in 1925 between the governments of the United Kingdom, the Free State and Northern Ireland, agreeing to maintain and respect the existing frontier.

A new phase in political affairs opened in 1932 with the advent of Eamon de Valera to power in the Free State. Tension arose in Northern Ireland with his policy of growing dissociation from the United Kingdom and the commonwealth and his substantial repudiation of the binding character of the 1925 agreement. His tariff policy also made the frontier between Northern Ireland and the Free State into a formidable economic barrier and rendered any possibility of being merged in the Free State extremely alarming to many interests and classes of people in Northern Ireland whose prosperity depended upon a flourishing export trade. The government of Eire, as the Free State then came to be called, made emphatic irredentist claims upon Northern Ireland.

During the same period Northern Ireland suffered from serious industrial depression and a recession of the export trade, while unemployment remained in the neighbourhood of 70,000 over long periods.

The Unionist party, standing for the maintenance of the union with Great Britain, gained a strong majority at every general election in Northern Ireland, whether for the parliament of Northern Ireland or for the province's representation at Westminster. Though united on this issue, the Unionist party allowed and experienced differing opinions in its ranks on a good many other issues. Sir James Craig (created Viscount Craigavon in 1927) was prime minister until his death on Nov. 24, 1940, when he was succeeded by John Miller Andrews, formerly minister of finance. In May 1943 Andrews was succeeded by Sir Basil Brooke (who was created Viscount Brookeborough in 1952).

The strategic importance of Northern Ireland, covering Britain's main shipping route, providing a landing place for the U.S. forces and filling the gap created by Eire's neutrality, was very great and was emphasized by Winston Churchill, Gen. Dwight D. Eisenhower and other war leaders. In addition the agricultural and industrial resources of the province were very valuable. Belfast constructed 600,000 tons of merchant shipping, a tenth of the output of the whole United Kingdom, as well as doing extensive admiralty work, including the building of six aircraft carriers, three cruisers and several other large ships, making a total of 140 warships of all sizes and 123 merchant ships. Northern Ireland produced other strategic materials and weapons, and because of its industrial importance Belfast was the target of several destructive air raids.

Postwar Developments.—In the period following World War II, Northern Ireland adopted schemes of social insurance, free health services and other aspects of the welfare state as they were introduced in Great Britain. Though a policy of nationalization was denied, steps were taken to unify a number of public services under newly created public authorities. Road transport had already been treated in this way in 1935, and the principle was extended to rail transport and electricity. As new types of public service came into being, it became necessary to amend the Gov-

ernment of Ireland act, 1920, in the United Kingdom parliament. New legislation was necessary to empower the government of Northern Ireland to proceed with its scheme of social insurance and state health services. But the essential principles of the 1920 act remained, and this amendment was only a natural development of the original principle that the government of Northern Ireland should control its own local affairs and welfare services.

In 1949 Eire, as the Republic of Ireland, withdrew from the commonwealth. To meet various legal problems arising from this, the United Kingdom parliament passed the Ireland act, 1949. This act contained the following provision: "It is hereby declared that Northern Ireland remains part of His Majesty's Dominions and of the United Kingdom and it is hereby affirmed that in no event will Northern Ireland or any part thereof cease to be part of His Majesty's Dominions and of the United Kingdom without the consent of the Parliament of Northern Ireland." Northern Ireland thus acquired something in the nature of federal status within the United Kingdom. This further cleavage with the Irish republic led to a revival of Irish Republican army (I.R.A.) outrages; in 1954 army barracks in Armagh and Tyrone were raided and incidents continued in the following years (the chief targets being communications and government or military installations), but after 1960 I.R.A. activities declined. By contrast the general election of March 1958 for the Northern Ireland parliament gave a clear Unionist victory of 37 out of the 52 seats, and in the United Kingdom elections the following year all 12 members returned to Westminster were Unionists. However, at a by-election in Nov. 1961 for one of the Queen's university seats, a Liberal member was returned for the first time.

Although the total value of trade rose steadily during the early 1960s, the primary industries of agriculture and shipbuilding suffered a long period of unfavourable conditions. The liner "Canberra" was launched in 1960 at Belfast, but conditions were generally unfavourable to shipbuilding, and the shelving of the Cunard line project for another "Queen" liner which might have been assigned to Belfast accentuated the situation. Unemployment was a constant problem, and at times over 40,000 men were out of work, although the average level was considerably lower. The government made serious efforts to meet these changing conditions by encouraging the development of light industries in Northern Ireland, which did bring about a diversification of economic activity. In 1961 the government economic advisory council was set up under Sir Douglas Harkness, permanent secretary to the minister of finance. (Hu. S.; X.)

POPULATION

The population of Northern Ireland has shown an increase at each census since 1891, when the figure stood at 1,236,056. At the 1961 census, a preliminary figure of 1,425,462 was recorded.

More than half the population lives in cities and towns. The boundary of Belfast is very restricted, and a "Greater Belfast" extends considerably into Antrim and Down; the inclusion of this area would bring the city's population to more than 500,000. Londonderry is the only other city with a population of more than 50,000. The following towns had populations of more than 10,000 in 1961: Newtownabbey, Bangor, Portadown, Lurgan, Lisburn, Larne, Ballymena, Newtownards, Newry, Coleraine and Carrickfergus (*qq.v.*).

Area and Population of Northern Ireland

Counties and county boroughs	Area (sq.mi.)	Population 1961			
		Urban	% of total	Total	Density (sq.mi.)
Antrim	1,176	113,353	41.4	273,923	232.9
Armagh	512	49,379	42.0	117,580	229.6
Belfast County borough	28	416,094	100.0	416,094	14,860.5
Down	952	82,600	30.9	267,013	280.5
Fermanagh	715	7,438	14.4	51,613	72.2
Londonderry (excluding county borough)	814	20,186	18.1	111,565	137.1
Londonderry County borough	4	53,744	100.0	53,744	13,436.0
Tyrone	1,261	27,353	20.4	133,930	106.2
Total	5,462	770,147	54.0	1,425,462	261.0

Religion.—About two-thirds of the population is Protestant and one-third Roman Catholic. In 1961 there were 498,031 Roman Catholics, 413,006 Presbyterians, 344,584 Church of Ireland, 71,912 Methodists and 97,929 others in Northern Ireland. (*See* also IRELAND: *The People.*)

ADMINISTRATION AND SOCIAL CONDITIONS

British antecedents, Protestant religion and economic interest caused a large proportion of the population of Ulster to resist all proposals for Irish self-government in the later 19th and early 20th centuries. The Government of Ireland act, 1920, was an attempt to give a measure of self-government to Ireland but at the same time to give the Ulster community guarantees against being placed under the rule of the predominantly Roman Catholic and nationalist majority in southern Ireland. The act set up two legislatures: one in Dublin for the 26 counties of southern Ireland and one in Belfast for the 6 counties of Northern Ireland. These two subordinate governments were to deal with local affairs, and all Ireland was to remain within the United Kingdom and to continue to send representatives to the United Kingdom parliament at Westminster. A common council of representatives from both north and south was to provide a link between Northern and southern Ireland and a means of discussing matters of common interest and extending co-operation.

This plan was accepted as a compromise in Northern Ireland but rejected in southern Ireland, which ultimately received dominion status as the Irish Free State in 1922. With modifications appropriate to these changed circumstances, the Government of Ireland act, 1920, as amended by the Irish Free State (Consequential Provisions) act, 1922, continued to be the basis of the constitution of Northern Ireland.

Constitution.—The essential feature of the constitution is that the province forms an integral part of the United Kingdom of Great Britain and Northern Ireland. Northern Ireland returns 12 members to the United Kingdom parliament and has a liaison agent (for government departments) in London, but within its own area a large range of legislative and administrative functions is delegated to the government of Northern Ireland. The formal source of executive power and the representative of the sovereign in Northern Ireland is the governor. The governor summons, prorogues and dissolves the parliament of Northern Ireland, gives the final assent to its legislation and fulfills other functions performed by the sovereign within the larger field of the United Kingdom constitution.

The parliament of Northern Ireland meets in the Parliament building at Stormont. There is a house of commons of 52 members elected by universal adult franchise from single-member constituencies, with the exception of the university constituency, which has 4 members, and there is a senate or upper house of 26 members, of whom 24 are elected by the house of commons on the principle of proportional representation. Each elected senator holds office for eight years, and half the seats in the senate are vacated every four years. The two other senators are the lord mayor of Belfast and the mayor of Londonderry, who become senators ex officio. The house of commons has a maximum life of five years. Members of parliament receive salaries. Each house elects its own speaker. Legislation going through the Northern Ireland parliament takes a course similar to that in the United Kingdom parliament, with the usual readings and committee stage in each house, but a finance bill can be passed by the commons alone. The houses can meet together in joint session in the event of a deadlock, but this has never occurred.

There is a prime minister of Northern Ireland and a small cabinet of ministers. A minister is permitted to introduce business, answer questions or make a statement in either house, but he can vote only in the house in which he has a seat. Ministers represent the following departments: finance, home affairs, labour and national insurance, education, agriculture, commerce, health and local government. The functions of these departments indicate the range of functions delegated to the parliament of Northern Ireland. A wide range of other subjects is entirely reserved for control and legislation by the United Kingdom parliament, in-

BELFAST TELEGRAPH

THE NORTHERN IRELAND PARLIAMENT BUILDING AT STORMONT, BELFAST; DESIGNED BY SIR ARNOLD THORNELY AND ERECTED IN 1928–32.

cluding the main forms of taxation, problems affecting the crown and succession, decisions about peace, war or neutrality and the armed services, relations with foreign powers or with other parts of the commonwealth, titles of honour, treason, extradition, naturalization, aliens, customs and excise, navigation by sea or air, post office, submarine cables, radio, lighthouses, coinage, weights and measures, trade-marks, copyright and patents. In these and some other matters, unless the exclusion of Northern Ireland is specially provided for, the province is legislated for in the United Kingdom parliament like any other part of the United Kingdom. Northern Ireland, for example, came under all food-rationing regulations which applied to the rest of the United Kingdom during and after World War II.

Political Parties.—After the general elections of May 1962, 34 of the 52 seats in the Northern Ireland parliament were held by the Unionists, who are affiliated to the Conservative and Unionist party in Great Britain and pledged to maintain the constitutional position of Northern Ireland within the United Kingdom. Because of the existence of heavy unemployment, the development and the diversification of industry in Northern Ireland are the most important of the Unionist party's domestic policies.

The Nationalists, who won nine seats, have the political objective of a united, independent Ireland. In pursuance of this policy, the Nationalists are supported by four other members: Independent, Independent Labour, Republican Labour and Eire Labour. The Northern Ireland Labour party, which is not to be confused with any of the above, held four seats. It is recognized by the speaker of the house of commons as the official opposition because the Nationalists, the biggest numerical group on the opposition benches, have refused to fill the role. The party supports Northern Ireland's constitutional position as part of the United Kingdom but is critical of the government's economic and social policies. The Liberal party returned one member.

Local Government.—There are five main types of local government authority in Northern Ireland. There are 6 county councils: Antrim, Armagh, Down, Fermanagh, Tyrone and Londonderry; the 2 county borough councils of Belfast and Londonderry; 9 borough councils, in Ballymena, Bangor, Carrickfergus, Coleraine, Enniskillen, Larne, Lurgan, Newtownards and Portadown; 25 urban district councils for various smaller towns; and 31 rural district councils. These bodies are elected by householders and owners of property in the areas which they serve. With the exception of rural district councils, they have power to levy rates. They work under the supervision of the ministry of health and local government.

Other Administrative Bodies and Public Services.—In addition to the local government bodies, there is a variety of boards and authorities established to do special administrative work or to organize public utility services. Most of these work under the supervision of one of the ministries. Thus the attention of the ministry of commerce is given to several administrative bodies, including the Ulster Transport authority (which is responsible for administering the whole road and rail transport system of the province, with the exception of municipal passenger transport and the work of private road haulage firms in Belfast and Londonderry), the Northern Ireland Electricity board and the Tourist board. Three agricultural marketing boards (for pigs, milk and seed potatoes) have been established under Northern Ireland legislation.

Other administrative bodies are associated with the work of the ministry of health and local government. Two are concerned with health services: the General Health Services board and the Hospitals authority. The Northern Ireland Housing trust builds workers' houses and co-operates with local authorities or acts as agent for them in the building of houses. It is financed by advances of capital from the ministry of finance. Other public administrative bodies include the Belfast Harbour commissioners and the Belfast City and District Water commissioners. Several public bodies established under the United Kingdom government also operate in Northern Ireland, including the British Broadcasting corporation and British European Airways. A number of steamship routes from Northern Ireland to Great Britain are operated by British railways.

Living Conditions.—The growth of Northern Ireland's industry after World War II, and the accompanying increase in prosperity, have meant a considerable rise in general living conditions. In the postwar years the standard of living is estimated to have increased by about 50%. The extent of the development is seen in the figures for firms employing 25 or more persons in the manufacturing industries, construction and services in which salaries and earnings of operatives have more than doubled since 1949.

Although employment continued to rise throughout the postwar years, the high birth rate, coupled with the reduction of labour requirements on the land due to greater mechanization in agriculture, has kept the unemployment figure in the region of from 6% to 9% of the total of insured workers.

In housing there has been a sustained and highly successful drive to provide new and modern living conditions for an expanding population. Since World War II well over 100,000 new permanent houses have been built by private enterprise, local authorities and the Northern Ireland Housing trust. In effect this means that since the war about one-third of the total population of Northern Ireland has been rehoused in modern dwellings.

Health and Social Welfare.—The general medical, dental, pharmaceutical and supplementary eye services are administered by the General Health Services board. These services are available without charge, save for the statutory charges common to the British National Health service, to all persons ordinarily resident in Northern Ireland. A hospital service is also available, administered by the Northern Ireland Hospitals authority.

Health authority services, including maternity services, immunization, aftercare and health education, are operated by municipal health authorities, who work in co-operation with the Hospitals authority and General Health Services board.

The county and county borough councils also act as welfare authorities in their respective areas. They provide residential accommodation for old people and others and are responsible for care of children, the blind and other handicapped persons. They co-operate with voluntary organizations and with the National Assistance board. The Assistance board gives grants and supplements, pensions and other national insurance benefits in cases of need and carries out certain work as agents for other organizations.

A comprehensive scheme of social insurance operates in Northern Ireland. Although separately financed, the plan is similar to that operating in Great Britain. It provides industrial insurance, unemployment benefit, sickness benefit, maternity benefits, retirement pensions and other allowances and grants. The scheme is administered by the ministry of labour and national insurance. Family allowances and noncontributory old-age pensions are also provided.

Justice and Police.—The superior courts in Northern Ireland, including the supreme court of judicature and the court of criminal appeal, are under the jurisdiction of the United Kingdom parliament. The supreme court has two main divisions, the high court of justice and the court of appeal, the former having in turn the three divisions of queen's bench, chancery and assize courts. From the court of appeal there is possibility of further appeal to the house of lords in certain matters, including, by leave

of the court, certain cases regarding the validity of acts passed by the parliament of Northern Ireland.

The inferior courts, dealing with minor civil and criminal matters, are under the jurisdiction of the parliament of Northern Ireland and are the concern of the ministry of home affairs. There are five county court judges, two of whom act as recorders of Belfast and Londonderry. County courts, which have a criminal as well as a civil jurisdiction, are held in 23 towns. Petty sessions courts are normally composed of a single resident magistrate, except in a few cases where two must adjudicate.

The police force, the Royal Ulster constabulary, is under the ministry of home affairs. The strength of the force is approximately 3,200. There is a special constabulary with a small permanent staff of about 100, its ranks being filled by citizens doing part-time training. Its total strength is usually about 10,000.

Education.—The statutory system of education is organized in three progressive stages: primary, secondary and further education. Primary and secondary education is provided in grant-aided schools that are attended by all but a small number of children. Primary schools provide for children under 11, and after this age those who fail to qualify for a scholarship to a grammar school, or who do not wish to attend a grammar school, proceed to intermediate schools. Secondary intermediate schools make possible the teaching of a wide variety of subjects, while technical intermediate schools provide specialized courses with emphasis on science and mathematics. All grammar schools provide an academic type of secondary education. There are many scholarships in higher education, and extensive technical education facilities are also available. There are two general training colleges for teachers which are financed by the ministry of education and students' fees. Three other teacher-training colleges are in operation, two operated by the Belfast County Borough Education committee for training of teachers of art and of domestic science, and the third, operated directly by the ministry of education, provides a three-year course for women teachers of physical education.

Queen's university, Belfast (founded as Queen's college in 1845; university status 1908), is a self-governing university. It receives parliamentary grants and also grants from local government authorities. It has about 4,500 students. Magee University college, Londonderry (established 1865), provides courses leading to the arts and economics degrees of the University of Dublin and Queen's university, Belfast. (X.)

THE ECONOMY

Despite considerable industrial development, Northern Ireland is mainly an agricultural country; agriculture ranks first both in the value of its output and in the number of people it supports. Many of the raw materials of industry are imported, and this imposes a burden on production costs. The continued concentration of manufacturing industry in the coastal towns is therefore to be expected. Nevertheless, expansion of population in Belfast and surrounding districts raises many planning problems not only for the metropolitan area but also for the remoter parts of the interior which are being depopulated.

Agriculture and Forestry.—The system of landholding, which replaced the notorious short tenancies of earlier times, was established by various Land Purchase acts between 1869 and 1925. Under them the land was sold to the occupiers, and most of the 74,000 holdings still pay land purchase annuities to the Northern Ireland government. Despite emigration and amalgamation, holdings are very small, nearly 60% being under 30 ac. Less than 6% exceed 100 ac., and only 1 farm in 14 employs permanent agricultural labour. The small family farm is a legacy of former subdivision, a custom established by tradition and persisting down to the Great Famine of 1846. The flax acreage, once extensive, has declined and now amounts only to a few hundred acres, though production was greatly expanded during World War II. Mixed farming is the rule. A large proportion of the crops grown goes to feed livestock and poultry, and farm incomes depend mainly on the sale of livestock and livestock products, including dairy produce. Oats, hay and potatoes are common crops, but wheat and barley production is mainly confined to relatively dry lowlands, such as the Ards peninsula in County Down. Barley production, however, is on the increase. Grass seed and seed potatoes for export are important cash crops, particularly in the Lough Neagh lowlands. North Armagh specializes in apples and soft fruits. Poultry, increasingly kept under the deep litter system, number over eight per head of the human population. There are approximately 1,000,000 cattle, and both sheep and pigs, whose numbers have been more variable, had reached about the same figure by the early 1960s.

The small owner-occupied family farm, now partly mechanized, is well adapted to quality production. With government inspection and marketing schemes, farm products have gained a high reputation for reliability. The main exports, in order of value, are fat and store cattle, eggs, bacon, milk products, potatoes, poultry, wool and fruit.

Only 1% of the land area of Ulster was classed as forest or productive woodland, mostly associated with landlords' demesnes, until after World War II. Reforestation on any scale was frustrated by the small size of the landholdings and by the joint ownership of many mountain grazings. A forestry policy, however, is being vigorously pursued by the ministry of agriculture. Over 1,500 men are now employed in the forestry service, and it is planned to expand the planted acreage in the 65 state forests. Much marginal land on the lower slopes of the hills can most profitably be utilized in this way, and considerable benefits are likely to accrue to employment and amenities in rural areas.

Fisheries.—Northern Ireland possesses both inland and sea fisheries of considerable value. The principal salmon fisheries are in the tidal portions of the rivers Foyle, Bann and Bush and at several stations along the coast. Trout and pollan are netted in Lough Neagh, and eels are caught there and in Lough Erne, but the bulk of the eel catch, which is marketed in London, comes from weirs on the lower Bann. Small fishing fleets operate from the harbours of Ardglass, Portavogie, Annalong and Kilkeel in County Down, taking whiting with the seine in winter and herring with the trawl in summer. Prawns (scampi) are caught between seasons. Inshore trawling and line fishing for plaice, skate and cod are pursued on the north coast of County Antrim.

Tourism.—The tourist industry has received statutory support since 1948 and has profited from the province's possession of such natural phenomena as the Giant's Causeway (*q.v.*), as well as from its wealth of antiquities and legends. Efforts have been made to improve tourist facilities and to attract a greater variety of visitors, the bulk of whom now consists of family parties from Scotland and northern England. An increasing number of visitors from North America are attracted in the search for ancestral homes, Ulster having contributed many emigrants in pre-Revolutionary times. The annual value of the tourist trade is estimated to be about £11,000,000.

Industry.—The textile industries, among which linen is traditionally the strongest, are the most varied and widely distributed of Northern Ireland's manufacturing industries. Most of them are located, however, in Belfast or within a 30-mi. radius of it. Flax, once home grown, is now imported from Belgium, the Netherlands and the Baltic lands. Spun rayon cloth has largely taken the place of linen, and cotton cloth as well as various mixtures are produced. The finishing trade, including bleaching, dyeing and printing, is well developed and attracts unfinished cotton and rayon goods from Great Britain. In addition there are other textile products of many kinds, both long-established manufactures, such as ropes, woolen goods and poplin, and new developments, such as viscose rayon yarn, hosiery and carpets. The Belfast ropeworks produces all classes of cordage, twines and fishing nets and has a large export trade. About 100,000 workers are employed in the textile industries, a declining proportion, now less than half, being in the linen industries, which have a capacity of 600,000 spindles and 23,000 looms.

The manufacture of clothing is carried on in many centres, notably Belfast and Londonderry, which specializes in shirts and pajamas. The industry employs about 25,000 workers. Among other long-established industries are tobacco, whisky and mineral water (soft drink) manufactures. Second only to the textile industries

in importance are shipbuilding and engineering, employing about 50,000 people, the largest single unit being the shipyards of Harland and Wolff at Belfast. The output capacity is of the order of 200,000 tons per year, and well over 100,000 tons of merchant shipping are normally produced, in addition to admiralty contracts. The aircraft industry, established on an adjacent site in 1937, employs about 8,000 workers. Other engineering manufactures are textile machinery, ventilation plants, turbines and agricultural machinery. The scope of the industry has been expanded to include a variety of precision and light-engineering goods, such as radios and electrical products and accounting machinery. The need for diversification of industry has been recognized since 1932 by government acts enabling capital grants and other forms of assistance to be given to new industries. Government-built factories, for instance, are provided and let at low rents. In 1955 the Northern Ireland Development council was established with the object of attracting new industries to assist in reducing unemployment: it is directing its attention particularly to industrialists in the United Kingdom and North America.

Mining and Power.—Small quantities of coal are mined, mainly near Coalisland, where, however, fire clay is a more important product. Extensive deposits of iron ore and bauxite, contained in the Tertiary interbasaltic beds of County Antrim, have been worked spasmodically, but they are of poor quality. Quarrying, for roadstone, limestone and granite and for sand and gravel, is an expanding industry, and among rare minerals valuable deposits of diatomite are worked in the lower Bann valley.

No large-scale hydroelectric schemes have been promoted in Northern Ireland, though the Erne loughs supply power to the Republic of Ireland. Hence, power production depends almost entirely upon imported supplies of fuel, which is a critical factor in production costs. The Electricity board and the Belfast corporation are the principal electricity distributing agents, operating to the requirements of the Northern Ireland Joint Electricity committee. An oil-burning station near Londonderry, opened in 1961, brings the available generating capacity to nearly 700,000 kw.

Trade and Finance.—For fiscal purposes Northern Ireland is part of the United Kingdom, and since customs entries are not required for cross-channel goods, the value of this trade can only be estimated. Moreover, these estimates, insofar as they are obtained from the returns of coastwise trade with Great Britain, include goods in transit from countries abroad through Great Britain and are therefore inflated. They are inflated also by the value of goods in transit to and from the Irish republic. In the early 1960s imports continued to exceed exports (in 1960 exports were valued at £334,301,000 and imports at £369,945,000). About 7% (mainly livestock) of the value of imports and 4% of the value of exports were accounted for by trade with the Irish republic. The principal imports were manufactured goods, fuel, raw materials, cereals and tobacco; the chief exports were textile goods, ships, machinery and farm produce, including livestock.

Three banks—the Belfast Banking Co. Ltd., the Northern Bank Ltd. and the Ulster Bank Ltd.—have their head offices in Northern Ireland. Business is also transacted by several other banks having their head offices in London, Dublin and Cork. The three Northern Ireland banking companies, as well as the Bank of Ireland, the Provincial Bank of Ireland Ltd. and the National Provincial Bank Ltd., issue their own notes.

As part of the United Kingdom, residents in Northern Ireland pay the same income tax and customs duties as those in Great Britain and use the same coinage. The bulk of the taxation is imposed and collected by the government of the United Kingdom, which makes certain deductions covering the cost of the armed services and reserved services (the administration of the post office, inland revenue, etc.) and remits the balance (the residuary share of reserved taxes) to the Northern Ireland exchequer. A Joint Exchequer board, consisting of a chairman appointed by the queen and a representative of her majesty's treasury and of the ministry of finance for Northern Ireland, determines the amount and allocation of the residuary share. The Northern Ireland parliament has control of taxation in such matters as death duties, stamp, motor vehicle and entertainment duties. It also raises money from time to time for capital purposes by means of stock and savings certificates.

Transport and Communications.—Northern Ireland is well provided with a close network of public roads, nearly all of which are maintained by local authorities with the assistance of grants from the road fund. The ministry of home affairs is directly responsible for the 380 mi. of trunk roads which carry through traffic. Much-needed improvements are in progress on these and many other roads. There are 2,688 mi. of main roads. The Transport act (Northern Ireland) concluded a series of enactments by which the Ulster Transport authority has become the sole public transport undertaking in the province, besides Belfast, which operates a municipal bus service. The railways have long been in financial difficulties, and altogether since 1920 over half the lines have been closed, leaving about 340 mi. open for traffic. The former Great Northern railway, linking Belfast with Dublin, is operated by the Ulster Transport authority as far as the border with the Irish republic. The high cost of public transport is a critical factor in the economic life of Northern Ireland, but more serious are the heavy sea transport charges which must be met by those industries which both import their raw materials and export their finished goods. Belfast has daily passenger and cargo services to Glasgow, Heysham and Liverpool, and regular freight services to Aberdeen, Ayr, Bristol, Cardiff, Dundee, Greenock, Leith, London, Manchester, Middlesborough, Newcastle, Preston, Stornoway and Swansea. There are daily services from Larne to Stranraer, which specialize in passenger, cargo and car ferry services, and daily ferry and ferry container services are maintained to Preston and Ardrossan. The only other ports with regular cross-channel transport services are Coleraine, Londonderry, Warrenpoint and Newry.

The length of inland waterways now in use is negligible, the only route carrying any goods being the Lower Bann navigation, which has a diminishing amount of traffic between Coleraine and Lough Neagh. The last surviving section of the Lagan canal to be operated was closed in 1958; the Newry Inland, Coalisland, Upper Bann and Strabane canals were abandoned earlier.

Regular daily air services operate between Belfast airport (Aldergrove) and London, Manchester, Liverpool, Birmingham, Newcastle, Leeds, Edinburgh, Glasgow and the Isle of Man. Additional flights to such centres as Bristol and Cardiff are available during the summer months, and charter services are also provided. A freight container service to various English towns was begun in 1960. Much post-office mail is carried by air: surface letters go chiefly by the Heysham route and parcel dispatches by Heysham and Stranraer. The post office in Northern Ireland is a reserved service under the ultimate control of the Westminster government.

Northern Ireland receives the four national radio programs broadcast throughout the U.K.; it is also served by the BBC, Ulster and ITA television facilities.

IRELAND, REPUBLIC OF (POBLACHT NA H-ÉIREANN), consists of the 26 counties of Ireland which became the Irish Free State, or Saorstát Éireann, in 1921 under an independent parliament, the *dáil*, with a governor general. In 1937 the country acquired a new constitution and the governor general was replaced

by a president. The 26 counties were then named Eire (Eng. Ireland) with the proviso that legislation did not apply to the six counties of Northern Ireland. At this time the link with the British Commonwealth was retained as "external association," but this was broken by the Government of Ireland act, 1949, when the 26 counties seceded from the commonwealth and became a republic (for the six counties *see* IRELAND, NORTHERN). The republic includes the whole area of the provinces of Leinster, Munster and Connaught, with three of the nine counties of the Ulster province, Cavan, Donegal and Monaghan. In 1921 it was intended that the border should be adjusted after an inquiry into the political sympathies of the inhabitants, but though a commission met, its findings were never published and the border consists of ancient county boundaries. The republic covers four-fifths of Ireland, 27,136 sq.mi.

I. HISTORY

Establishment of the Irish Free State.—The intensive conflict which took place during and after World War I and is known in Ireland as the Anglo-Irish war resulted in the Irish peace agreement, which was signed in London by British and Irish plenipotentiaries on Dec. 6, 1921. The agreement provided that Ireland should thenceforward have the "same constitutional status in the Community of Nations known as the British Empire" as had the dominions of Canada, Australia, New Zealand and South Africa; "with a Parliament having powers to make laws for the peace, order and good government of Ireland and an Executive responsible to that Parliament." The new dominion was to be known as the Irish Free State. This peace agreement was ratified by the British parliament on Dec. 16, 1921, and became operative when it had also been passed on Jan. 15, 1922, by a meeting of the parliament of southern Ireland convened by Arthur Griffith. The new state included only 26 of the 32 Irish counties, as the northeastern area, known as Northern Ireland, was to decide whether or not it would accept inclusion in the dominion.

The peace agreement had been concluded between the British government and the representatives of an Irish government which it had previously refused to recognize. The Irish representatives held their authority from *dáil éireann* (the assembly of Ireland), which had come into existence in Jan. 1919. The general elections held at the end of 1918 had resulted in an overwhelming majority for Sinn Fein as the party which declared for an Irish republic. All members elected for any Irish constituency were invited to attend an assembly in Dublin on Jan. 21, 1919, but in fact only the Sinn Fein members attended. Acting as a constituent assembly for all Ireland, they then proclaimed the Irish republic in existence, and they elected a president and ministers. Eamon de Valera (*q.v.*) was then in prison in Lincoln jail, but was regarded as president designate. He was to be both national president and chief executive, as in the United States. But the immediate concern of *dáil éireann* in Jan. 1919 was to present Ireland's claim to national independence at the international peace conference which was then assembling at Versailles.

In the period of acute Anglo-Irish conflict which ensued, *dáil éireann* regarded itself as the constitutional legislature of Ireland. The British government did not accept that claim until it signed the treaty of Dec. 6, 1921, and agreed to the establishment of the Irish Free State. The negotiations had been begun in July between De Valera and David Lloyd George, but were soon entrusted to plenipotentiaries, who were appointed by De Valera but required to consult closely with him while the negotiations proceeded. The final agreement was reached in Downing street only after Lloyd George had delivered an ultimatum threatening "immediate and terrible war" if the terms were not accepted at once. Griffith, Michael Collins (*q.v.*) and E. Duggan then agreed to sign, and Robert Barton and Gavan Duffy added their signatures under protest. Their chief objections were to the prescribed oath of allegiance to the British crown and to the provisions which allowed Northern Ireland to remain outside the new state.

During the interval between the assembling of the first *dáil éireann* in Jan. 1919 and the conclusion of the treaty in Dec. 1921, the British parliament had in 1920 passed an act to establish two Irish legislatures, one for the 6 counties of Northern Ireland and the other for the remaining 26 counties. Both parliaments and their executives were to possess identical powers, much more restricted than had been conceded under the prewar Home Rule bill, which had been enacted in Sept. 1914, though its operation was indefinitely suspended. But under this Government of Ireland act of 1920, general elections were held in Ireland so that the two Irish parliaments should be brought to life. In the 26 counties every constituency except Dublin university returned a nationalist candidate; and even in Northern Ireland some seats were also won by Republicans. All except the four members for Dublin university refused to bring the southern Ireland parliament into operation, and it consequently never functioned. But the same Republican members who had been elected in 1920 assembled for the first time on Aug. 16, 1921, in the Dublin Mansion house, after the truce had brought an end to military hostilities. They then constituted themselves the second *dáil éireann*, and all members took the oath of allegiance to the Irish republic while negotiations were proceeding between De Valera and Lloyd George. Soon afterward plenipotentiaries, led by Griffith and Collins, were appointed by De Valera to conclude the peace agreement, which eventually fell short of the full Republican demands.

The Provisional Government.—Although the British parliament ratified the peace agreement on Dec. 16, De Valera immediately repudiated it, on the ground that the plenipotentiaries had departed from their instructions. In *dáil éireann* a long and bitter debate developed, and on Jan. 8, 1922, ratification was passed by a majority of only 64 to 57. De Valera at once resigned the presidency, and Griffith was elected to replace him, but by a majority of only two votes. A provisional government was then appointed under article 17 of the treaty, by a meeting to which all members elected in 1920 for the southern Ireland constituencies were summoned. Those who had opposed the treaty refused to come, and the provisional government was composed largely of men who were little known in public life. Griffith as president remained outside the government, as did Gen. Richard Mulcahy, who then became minister for defense. Collins, who had attained an almost legendary reputation and great popularity by his daring and energy during the Anglo-Irish war, was appointed head of the provisional government. The only minister whose name was well known was Eoin (John) MacNeill, who had long been prominent in the Gaelic league and as founder of the Irish volunteers. The others were still young men. In opposition to the government were De Valera and most of the active leaders of Sinn Fein. The armed forces were still nominally the army of the republic, and their allegiance was divided. The old police force was disbanded, and a new force, the civic guard, was formed at once; but it was to be unarmed.

Griffith and Collins desired an immediate general election to obtain a verdict for the treaty. But De Valera anticipated them by convening a full convention of Sinn Fein delegates, and in the

interests of maintaining national unity Collins then agreed to delay the election. There was still a dim hope of inducing Northern Ireland to come into the new dominion, and an attempt was made by the provisional government to negotiate with Sir James Craig (later Lord Craigavon), the Northern Ireland prime minister. But in Belfast fierce sectarian riots were raging, and these approaches had no success. In the meantime defiance of the provisional government began to spread, and De Valera proclaimed openly that only the Republican *dáil* had legitimate authority. Many of his followers were calling for renewed military action against the British government. Incidents of open defiance and violence became frequent, but Collins was always determined to avoid taking punitive action, though Griffith was believed to consider it necessary. Collins reached an agreement with De Valera, which was announced on May 20, that elections should be held on a basis of putting forward candidates representing both sides in the same proportion as in the existing *dáil*. A coalition government would then be formed after the elections, in which De Valera would have four seats and the protreaty party five. All parties were urged to refrain from proposing candidates other than those selected from this joint panel. Moreover, the election was not to be regarded as a verdict for or against the treaty. But this arrangement was out of touch with general feeling in the country. The Irish Labour party gave a lead in putting forward its own candidates. Many others also came forward, and at the June 16th elections, 34 members were elected who were not on the joint list, all of them being in favour of accepting the treaty. Of the panel candidates who were elected, 58 were protreaty and 36 Republican.

Although faced with this decisive defeat, the Republicans maintained that the republic was still in existence and refused to recognize any other authority than the Republican minority of the second *dáil*. The Irish Republican army (I.R.A.) soon took the law into its own hands, and large areas in the south and west were more or less under its control. Acts of violence and arson became more frequent, and the British government was soon accused in England of having let loose conditions of anarchy without protecting its friends. A crisis arose when Field Marshal Sir Henry Wilson was shot dead on June 22, on his own doorstep in London, by two Irishmen who had served in the British army during World War I. Drastic action to restore order in Ireland was demanded from London, and an open conflict became inevitable on June 28. The Republicans in Dublin seized the assistant chief of staff of the Irish army as a hostage and imprisoned him in the Four Courts, which they had occupied. The provisional government demanded his immediate release and besieged the courts. Serious fighting in Dublin ensued for a week, until Rory O'Connor, who had occupied the courts, blew them up before surrendering. British military equipment and munitions had been supplied to assist the government, and the conflict was assuming a new phase. Meanwhile De Valera, who had escaped to the southwest, was openly supporting the insurgents. Griffith and Collins decided that there could be no further compromise, and Collins assumed charge of the army as commander in chief. The strain had told so heavily upon Griffith that he died suddenly on Aug. 12. Then Collins rashly left Dublin to inspect the military operations in the south. On Aug. 22 he ran into an ambush in west Cork and was shot dead.

The provisional government had thus lost its two most prominent leaders within a fortnight, while De Valera was openly heading the insurgents in the west. The surviving ministers could not even appear openly without armed protection and were obliged to live at the central government offices which had been established in the college of science. Under the treaty the newly elected *dáil* was required to frame its constitution before Dec. 6, 1922, and the new constitution had then to be ratified also by the British government. The new *dáil* was therefore summoned to meet on Sept. 9, in the building of the Royal Dublin society, Leinster house, which later became the seat of both the *dáil* and senate. The building was for some time kept closely guarded.

Its first business was to elect a new president in place of Griffith. None of the acting ministers had yet attained a national reputation, but W. T. Cosgrave (*q.v.*) was older than most of the others, with active experience as a member of the Dublin corporation, and he had shown great competence and energy as minister for local government during the Anglo-Irish war. He was now chosen as president, and the *dáil* also elected a team of 11 ministers whom he proposed. It then had to pass the clauses of the constitution defining relations between the Irish Free State and the crown, and questions of imperial defense, which Griffith had already settled with the British government. In the absence of the Republican deputies, who refused to recognize the new *dáil*, the work proceeded swiftly, and the constitution was ratified both in Dublin and in London by Dec. 6.

Open conflict between the armed forces of the Republicans and of the Free State had ceased by the autumn, but public order and security were still being widely violated in many districts. Courts had not yet been formally constituted, and the new police, or civic guard, had to be organized and trained under great difficulties. Kevin O'Higgins, as minister for justice, insisted that the police must be unarmed, in contrast with the old royal Irish constabulary. They were consequently at a grave disadvantage in restoring public order while irregular Republican forces were still active. The government had to rely on military forces, which were hurriedly recruited until they exceeded 50,000 men. Under such conditions, trial by jury could not be expected to obtain convictions. The *dáil* authorized trial by court-martial, with drastic punishments. But the prisons were already filled with men awaiting trial for reasons which usually had some political pretext. Attacks upon life and property were still widespread, and agrarian outrages were reoccurring. The government decided that the unauthorized possession of firearms must be resolutely punished, and in November it was solemnly announced that four men had been tried, convicted and executed on the sole charge of having revolvers without licence. Other similar trials soon followed, and Robert Erskine Childers (*q.v.*) was likewise executed after he had been found to have a revolver. These executions were fiercely resented by the Republicans and embittered Irish politics for years afterward.

The Cosgrave Ministries.—By Dec. 6 the new Irish constitution had been ratified, both by the *dáil* and at Westminster. The new ministry had to test its own powers while labouring to restore confidence and good order. A crisis arose on Dec. 8, when the *dáil* met to choose a senate under the new constitution. One member of the *dáil* was shot dead and another wounded on their way to the meeting. The government decided upon immediate reprisals against the Republican leaders, and on the following day four of the principal insurgents, one from each province, were shot in prison without trial. They included Rory O'Connor, who had seized the Four Courts in June. Republican opposition to the government became more bitter than ever, but there was soon a lessening of organized resistance. More than 10,000 prisoners had been placed under restraint, and there had been about 50 executions. In May 1923 De Valera openly appealed to the Republicans to cease fighting and to conceal their arms. Soon afterward it was found generally possible to hold public meetings.

Confronted with the problems of civil war and with responsibility for reorganizing the country's normal life, the young ministers under Cosgrave's leadership displayed remarkable ability and energy. They were untrained either by office or by public experience, and they were regarded by their former Republican comrades as having betrayed their oath to the republic. But they received more encouragement than had been expected both from the conservative elements in Ireland and from the British government. At the outset they had applied to London, with success, for the appointment of an Irish nationalist as the first governor general of the Free State. They suggested T. M. Healy (*q.v.*), a veteran of Charles Stewart Parnell's agitation who in later years had shown his active sympathy with Sinn Fein. In approving his nomination, the British government went far toward creating a sense of cooperation and mutual confidence. It also showed its willingness to admit the wider implication of dominion independence, which the Irish ministers soon found other opportunities to press forward. But the first necessity was to restore public order and to bring the new constitution into operation.

The first senate was duly created, and Cosgrave gave generous representation to the former Unionists when he had to nominate half its membership. It elected as its first chairman Lord Glenavy, who as Sir James Campbell had been Sir Edward Carson's principal colleague in the campaign to resist home rule before World War I. But the Northern Ireland government was then headed by Sir James Craig, since Carson's retirement, and it had formally notified the British government that it would not join in the Irish Free State. By April 1923 the Free State had consequently been obliged to establish a customs system along the border of Northern Ireland and also in the Irish ports. Cosgrave was still finance minister, as well as head of the government, and the British financial system was still being operated, though preparations were being made for protective tariffs.

At the end of August, when order was generally restored and De Valera had instructed his followers to abandon armed resistance, the fourth *dáil* was elected, on a basis of adult suffrage for men and women. De Valera retained his personal following, and his party won 44 seats out of 128. Cosgrave's party did not secure half the total of seats; but as the Republicans refused to sit in the new *dáil*, Cosgrave had a majority among those who did attend, and on many issues he had general support from Labour and the others. The absence of any effective opposition party greatly strengthened the power of the new government to carry measures quickly, and it displayed great energy in the following years. In September the government sent its official representatives to attend the council of the League of Nations, and soon afterward the Irish ministers, headed by Cosgrave, took part in the Imperial conference in London. These contacts soon led to co-operation with several other dominions in pressing for a more definite recognition of sovereign rights.

An executive council of seven ministers with four other "extern" ministers was established after the elections of Aug. 1923. Ernest Blythe then became finance minister, and in December he succeeded in floating the first national loan of £10,000,000 at 5%, repayable in 20 years. Blythe courageously faced the unpopular task of collecting arrears of taxes and land annuities which had been withheld during the years of unrest. He reduced old-age pensions and made other unwelcome cuts in expenditure, and by introducing a protective tariff he caused new dislocation of trade which could not be expected to produce immediate benefits in increased employment.

Reconstruction and Progress.—Patrick Hogan, as minister for agriculture, had already completed land purchase by the tenant farmers. He introduced a licensing system for the export of butter and eggs which soon resulted in higher prices when it was found that a high standard was enforced and that regular deliveries could be ensured. He also provided long-term credits to farmers. His energy and knowledge of Irish agriculture, combined with great gifts of popular appeal, produced remarkable results, which were hastened by the skilful assistance of John Dulanty as trade commissioner in London. Other economic developments were inspired by bolder conceptions than had ever been attempted under British rule. The government was offered assistance by the Siemens company in Germany for introducing electric power on a national scale by harnessing the river Shannon. P. McGilligan as minister for industry and commerce accepted early in 1925 the German company's offer to undertake a full survey at its own expense on condition that Siemens would get the contract if the work proved economically desirable. Its report, after approval by an independent committee of international experts, was then adopted. The Shannon scheme provided for utilizing three lakes in stages, as reservoirs to meet future requirements. All three were brought into operation much sooner than had been foreseen, and the Shannon power was later supplemented by other similar sources. Another new enterprise was the introduction of beet sugar factories, under a scheme which provided a government subsidy of more than £1,000,000 to a Belgian firm which undertook to organize the industry.

Reconstruction proceeded vigorously in other directions also. Political control of the elected corporations in Dublin and Cork, and of some county councils, led to such conflicts with the government that it boldly suppressed the corporations, in disregard of their long association with the nationalist agitation. City managers were appointed, and they soon removed old abuses and reduced the prevalent corruption while introducing useful reforms. District councils were abolished and their powers transferred to the county councils; and the central government exerted its authority with increasing disregard for local objections. O'Higgins, the young minister for justice, was particularly high-handed in carrying out his reforms, and he enforced drastic and unpopular restrictions on the drink trade. He had created an efficient, though unarmed, civic guard, which replaced the old royal Irish constabulary with a much smaller and less expensive force. The unpaid justices of the peace were abolished and district justices for each area were appointed instead. The high court judges ceased to go on circuit, and circuit judges were appointed. Many of these judges were young men of outstanding ability who brought integrity and enthusiasm to their work.

The Ulster Boundary Crisis.—The Republicans, who still held more than 40 seats in the *dáil*, had repudiated the treaty mainly because it allowed Northern Ireland to remain separate. Collins had been convinced in his negotiations with Lloyd George that the treaty supplied a solution, by providing under article 12 that if Northern Ireland did not come into the Free State there must be a boundary commission to decide what areas were to remain excluded. Two of the six excluded counties, Tyrone and Fermanagh, contained clear, though small, majorities in favour of union with Ireland; and on the southern side of both Down and Armagh were substantial areas which had for years returned nationalist members. Collins, like most Irish nationalists, had assumed that when a boundary commission was set up these areas would all be withdrawn from Northern Ireland and that the remaining territory would be too small to continue as the basis of an independent legislature and government.

In 1924 Ramsay MacDonald's Labour government had taken office, and soon Cosgrave demanded that the commission be set up to "determine in accordance with the wishes of the inhabitants, so far as may be compatible with economic and geographical considerations, the boundaries between Northern Ireland and the rest of Ireland." The Northern Unionists quickly organized preparations to resist any interference, and Craig was soon threatening to revive the Ulster volunteers. Attempts to obtain a settlement by consent failed, and when Eoin MacNeill was appointed to represent the Free State on the boundary commission the Northern government refused to appoint a representative. The dispute was referred to the judicial committee of the privy council, which decided that legislation was necessary if a representative of Northern Ireland were to be appointed by the imperial government. An act for that purpose was accordingly passed, and MacDonald appointed a well-known Ulster barrister, J. R. Fisher, to represent Northern Ireland. As chairman, Judge Richard Feetham was brought from the Union of South Africa. During 1925 the commission conducted its inquiry in secret, but in November MacNeill resigned in protest when a London newspaper published a detailed anticipation of its report which suggested that the alterations would be small and even adverse to the Free State in important areas.

MacDonald then called a conference in London, which Craig attended, and a new agreement was made which left the existing boundaries intact in consideration of large financial concessions. Under article 5 of the treaty, Ireland had accepted liability for part of the United Kingdom's public debt in 1921, to be determined "in such proportion as may be fair and equitable, having regard to any just claims on the part of Ireland by way of set off, or counterclaims." This article, as well as article 12, was then canceled, while Ireland agreed to pay a revised claim in compensation for war damages, estimated at less than £5,000,000.

Removal of this uncertain but great financial liability was an immense help to the Irish government, but the agreement involved surrender of all hopes of compelling Ulster to come in. The agreement was vehemently opposed by the Labour party, as the *dáil* had not been consulted before it was made. The Republicans renewed their accusations that Ireland's national integrity had been sur-

rendered, and even the supporters of the treaty were shaken in their confidence. But the danger of collision with the Northern Ireland government was removed, and it at once disbanded two of the three branches of the Ulster special police force. The approach of another Imperial conference gave opportunities to press for fuller independence. Ireland was already actively participating in the League of Nations, and both at Geneva and in the Imperial conference collaboration with other dominions was pursued, to develop greater freedom from imperial control. Passports for Irish citizens were now issued from Ireland; the authority of the governor general in regard to diplomatic and other appointments was subjected to increasing restrictions; and the right of appeal from Irish courts to the judicial committee of the privy council was strongly contested. These and other matters affecting the implications of dominion status were considered, with growing support from Canada and South Africa.

Republicans in the Dáil.—By the spring of 1927, five years of intensive work had produced striking progress. Income tax had been lowered below the English rate to 3*s.* in the pound. The fourth *dáil* alone had passed nearly 200 acts, and a sense of security had been achieved. But there was a natural desire for change, and when general elections were held in June the smaller parties increased their strength. Cosgrave's party was reduced from 57 seats to 46 and could no longer command a majority, even while the Republicans remained outside the *dáil*. But Cosgrave agreed to form a new ministry. Among the other ministers, Hogan, McGilligan and Blythe had shown great abilities, but O'Higgins had made the strongest mark, especially at the Imperial conference and in Geneva. He became vice-president of the executive council. But his sardonic wit and provocative speeches had incurred intense resentment during the civil war. The old feuds were suddenly revived when he was murdered by gunmen outside his house on Sunday, July 10, 1927.

Cosgrave denounced his murder as a deliberate attack on the state. He took drastic powers by carrying the Public Safety act, which proclaimed all revolutionary societies as treasonable and gave power to arrest or deport suspected persons. The Republicans still refused to enter the *dáil* and continued their efforts to discredit the government from outside. Cosgrave decided to force them to come in by introducing a bill which prescribed an oath of willingness to enter the *dáil*, and also an oath of allegiance to the constitution, for every candidate at future elections. De Valera at last decided that he and his party would subscribe to the oath, but only after proclaiming that they regarded it as an "empty formula" which would have no binding force. He then led his followers into the *dáil*, and an agreement was reached with T. Johnson's Labour party, and with Capt. W. A. Redmond's National league, that they would outvote the government on a motion of no confidence. Johnson was to assume office with the support of the Republicans. The motion was debated on Aug. 16, but one member absented himself and Cosgrave's ministry was saved by the speaker's casting vote. He at once dissolved the fifth *dáil*. The two main parties gained heavily from their previous allies, and Cosgrave won 61 seats as against 57 won by the Republicans.

The sixth *dáil* assembled in Oct. 1927, and Cosgrave again formed a ministry, with support from the Farmers' party and independents. De Valera was now leading the opposition in the *dáil*, supported generally by the Labour party and the National league, and an alternative to the Cosgrave ministry could easily be formed. The government had exercised almost unchallenged authority and had introduced a great number of drastic changes, many of them unpopular. Economic conditions favoured them during the sixth *dáil*, until the general trade depression of 1930 began to affect Ireland also. Cosgrave's ministry, while introducing protective tariffs and encouraging the foundation of new industries behind the customs barrier, had relied chiefly upon trade with England. Agriculture had benefited from that policy and from taking advantage of imperial preferences in which the Free State shared. The economic crisis in England brought down prices for Irish produce, and unemployment was spreading. Discontent gave new life to the activities of the Irish Republican army, and Cosgrave introduced yet another amendment to the constitution to establish a military tribunal for political crime. De Valera opposed it, with increasing support, and in Feb. 1932 the general elections produced the seventh *dáil*, in which De Valera had gained enough seats to form a ministry, with the Labour party's support.

De Valera's First Ministry.—After ten years in office, Cosgrave had been prime minister longer than almost any other statesman in Europe. But De Valera had been the Republican leader since 1916, as the senior survivor of those who escaped execution after the rising. He had a definite program which appealed especially to the poorer classes, who felt that Cosgrave had chiefly encouraged the large farmers and the middle classes. With trade depression increasing, De Valera promised relief by wider social services, by reducing the high salaries of public officials and especially by his promise to withhold the land purchase annuities which were being paid to the British government. This promise was especially effective in the western counties, where the land annuities were the principal outgoings of the small farmers. At the same time he renewed his appeal to national sentiment by demanding the removal of the oath of allegiance and the abolition of the governor general as representative of the king.

De Valera's refusal to continue payment of the land purchase annuities produced an economic conflict with Britain which enabled him to press at the same time for abolition of the oath of allegiance. The annuities had been canceled by the Government of Ireland act of 1920, which never became operative, but Cosgrave's government had subsequently accepted liability for paying them as part of the financial agreement of 1926, which abolished all Irish liability for the imperial public debt in compensation for throwing over the promised adjustment of the Northern Ireland boundaries. De Valera claimed that this agreement was invalid because it was never submitted to the *dáil*. The British government insisted that the moneys were due and J. H. Thomas, as secretary of state for the colonies, retaliated by securing the imposition of tariffs on imported Irish cattle and farm produce. De Valera then imposed a similar punitive levy on English coal and other imports. The annuities were still collected, but for the Irish exchequer. An economic war developed with crippling results for the more prosperous Irish farmers, though the small farmers were less directly affected. Denmark and the dominions had new opportunities of capturing the English market from their Irish trade rivals; and at the Ottawa conference later in 1932, Ireland gained no benefit, whereas Cosgrave had always obtained sympathetic support at such conferences. Nevertheless the economic war had created favourable conditions for De Valera to pursue his deliberate policy of achieving full political and economic independence. A conflict with the governor general, James MacNeill, after the Eucharistic congress in June enabled him to demand MacNeill's retirement, and he then insisted successfully in asserting the right to nominate MacNeill's successor. The Viceregal lodge ceased to be the official residence, and D. Buckley, a veteran of the Gaelic revival who had taken part in the rising of 1916, became governor general, living in a modest house in south Dublin. By simple legislation De Valera abolished the oath of allegiance as prescribed by the treaty. While the economic war continued, protective tariffs were used with increased vigour to promote a general policy of achieving economic self-sufficiency. An offer by the British government to invoke arbitration on the disputed land annuities, by a commission which would include no members of the commonwealth, was rejected by De Valera, and the conflict became more intense. In Jan. 1933 he appealed directly to the country, and in the eighth *dáil* he had 77 seats instead of 70. The Labour party continued to support him.

Internal troubles increased with the growth of unemployment and the depressing effects of the economic war. Evidences of Communist influence began to appear, especially among the I.R.A. The Army Comrades association formed a new organization of national guards, led by Gen. Eoin O'Duffy, whom De Valera had dismissed from command of the civil guard. Demands from the I.R.A. for his dismissal had made De Valera's action appear as a weakening of his authority, and O'Duffy soon became prominent as leader of the Blue Shirts, which came into collision with the government. De Valera now invoked the Public Safety act against

O'Duffy's Blue Shirts and declared the national guard an illegal organization. While the economic war continued, De Valera exploited his opportunities for reducing any formal dependence upon the British connection. Cosgrave's government had already achieved notable advances toward full autonomy by gaining the support of other dominions at the Imperial conferences. Ireland had been actively represented in the League of Nations since 1923, and in Sept. 1932, shortly after assuming office, De Valera had been elected president of the League's council and had made a notable presidential address at Geneva. During the Spanish civil war he had supported the British attitude of nonintervention. But he had abolished the oath of allegiance and forbidden appeals to the judicial committee of the privy council. He had reduced the governor general's status to a minimum, and he announced his intention of framing a new constitution. The senate, which still represented chiefly the conservative elements, with a large proportion of former Unionists, was to be replaced by a more widely representative body. With continued support from the Labour party, De Valera had been pursuing his policy of self-sufficiency and extending the social services. Tension in the economic war was partly relaxed in 1935 when a coal-cattle agreement was negotiated, after much skilful diplomacy, by Dulanty as high commissioner in London. These agreements were renewed in 1936 and again in 1937.

Constitution of 1937.—De Valera proceeded to introduce his proposals for the new Irish constitution, "as if there were no relationship with the states of the British Commonwealth." His proposals were introduced when the British government was unexpectedly confronted with the constitutional crisis that resulted in the abdication of King Edward VIII. Under the Statute of Westminster each dominion was expected to ask the imperial parliament to enact a statute of abdication; but De Valera declined to make any such request. The *dáil*, however, passed an act accepting the abdication, and it authorized King George VI to act as a symbol of Ireland's co-operation in the commonwealth on such matters as the Irish executive council might refer to him for advice. De Valera had thus gained a direct opportunity for establishing his own conception of Ireland's special position as a state in "external association" with the British Commonwealth.

The new constitution gave effect to this general idea. It did not proclaim a separate and independent republic, but it abolished the title of the Irish Free State and substituted the word "Eire" (Ireland). The British government accepted these proposals, in spite of protests from the Northern Ireland government. De Valera held another election to secure approval of his proposals, and the new constitution was formally ratified by a plebiscite which was held concurrently with the elections. It became operative on Dec. 29, 1937. One symbolic change was that the former governor general was now replaced by a president, elected by the whole people, who was to be the nominal head of the state. The leader of the largest party in the *dáil* was to be prime minister. The first president, elected by the consent of all parties, was Douglas Hyde, a famous Celtic scholar who had been the chief organizer of the Irish language revival and president of the Gaelic league. As a Protestant, the son of a clergyman and a graduate of Trinity college, Dublin, his unanimous choice was regarded as evidence of good will toward the Anglo-Irish minority.

The Naval Bases.—Events in Europe were creating a new situation, which concerned De Valera directly in his dual capacity as prime minister and minister for external affairs. As president of the League of Nations council at Geneva in 1932 he had spoken gravely of the risks of war. The growing fears of a European war had a direct concern for Ireland, because the Anglo-Irish treaty had left certain naval bases in Ireland under British occupation. Cork harbour and Berehaven in the southwest, besides Lough Swilly in the north, were still occupied by the British fleet. In the event of war in Europe, this would involve Ireland inevitably as a participant. The Republican program, to which De Valera was irrevocably committed, demanded absolute independence and sovereignty for the whole island, which implied an unfettered freedom of decision. De Valera had insisted repeatedly, in all negotiations with London, that in the event of war Ireland would never give active support to England while partition continued. Because war was apparently imminent, Neville Chamberlain had to face the probability of renewed difficulties in Ireland if the British naval bases there became isolated. The new Irish constitution, evolved after several years of economic conflict, showed that De Valera was uncompromising in his claims to sovereignty but anxious to restore friendly relations. Chamberlain's government accepted the new situation in Dec. 1937 by announcing that the British and dominion governments "are prepared to treat the new constitution as not effecting a fundamental alteration in the position of the Irish Free State."

Anglo-Irish Agreement of 1938.—Chamberlain then invited De Valera to hold new discussions in London covering the whole position. Conversations were accordingly opened in Jan. 1938 and resulted in three agreements on April 25. The preamble announced that they had been made with the object of promoting friendly relations between the two countries, of facilitating trade between them and of reaching a final settlement of all financial claims. The agreements went far beyond the immediate dispute concerning the land annuities and the resulting economic war. They made a dramatic change by relinquishing British occupation of the Irish naval bases outside Northern Ireland. The treaty of 1921 had provided that until arrangements were made between the two governments for the Irish Free State to defend its own coasts, "the defence by sea of Great Britain and Ireland should be undertaken by the imperial forces." De Valera then claimed that Eire was prepared to undertake its own coastal defense, while Chamberlain recognized the obvious difficulties in maintaining isolated naval bases in case of war. Chamberlain decided to rely upon Irish good will in withdrawing the British naval forces. It was agreed that before Dec. 31, 1938, the United Kingdom would transfer to Eire the property and rights of the admiralty at Berehaven and also the harbour defenses there and at Cork harbour and Lough Swilly. This part of the new agreement was vehemently opposed by Winston Churchill, who was not then in office, on the ground that British naval defense would be greatly hampered by the surrender of the Irish bases.

Besides terminating the British naval occupation, the agreements provided for a settlement of the land annuities dispute and a cessation of the trade war. The original treaty had contained vague provisions for adjustment of financial claims on both sides, but these had been generally settled by the agreement of 1925 which abolished the Ulster boundary commission and canceled almost every outstanding financial liability except the land annuities. It was then agreed that, apart from a separate payment for damages to British property which had been agreed upon in 1925, Eire should pay £10,000,000 to the British government before Dec. 1938. This was to be a final settlement of all outstanding claims between the two governments. At the same time the British government was to abolish the special duties which had been imposed to collect the amount claimed for the land annuities. De Valera had utilized the abnormal situation to develop new Irish industries behind protective tariffs, and the money collected for land annuities was spent on subsidizing exports. The new agreements brought an end to such penal tariffs on both sides; but Irish trade was already beginning to follow a new pattern, and exports to Britain were prejudiced by the loss of preferential treatment.

Irish Neutrality.—The new Anglo-Irish agreements, much wider in scope than had been expected, enabled De Valera to appeal for a new verdict of popular approval. The *dáil* approved the new pact on April 29 with only one dissentient, and the general election on June 17 returned De Valera to power with a clear majority, having 77 votes against 45 for Cosgrave's Fine Gael, 9 Labour and 7 independents. On July 11 the last British troops were withdrawn from Cork harbour. Events in Europe were shaping rapidly, but Chamberlain had been fully aware that the Irish government might proclaim its neutrality in case of war. He had told the house of commons plainly, in explaining the agreements on May 5, that De Valera had attached primary importance to the question of partition, which the British government had considered itself unable to discuss. In a statement published on Oct. 18, shortly after Chamberlain's return from his visit to Hitler

in Munich, De Valera declared that "quite obviously the existing partition would be a grave danger to England in the event of that country becoming involved in a European war." He asserted that "we have definitely committed ourselves to the proposition that this island shall not be used as a base for enemy attacks on Great Britain," and that quite possibly "a united free Ireland" would be willing to co-operate with Britain to resist a common attack. But until there was a "united, free, independent Ireland," Irish support could not be expected. In the same interview De Valera expounded his own views on the possible settlement of partition. He agreed, though reluctantly, that Northern Ireland might keep its "local Parliament with its local powers," but that "the powers at present reserved to the English parliament shall be transferred to the all Ireland Parliament."

A series of bomb outrages committed by the I.R.A. in Belfast and in English cities during the following winter and spring aroused anger in England and compelled the Irish government to tighten its control by new legislation against subversive activities. But on April 16, 1939, De Valera announced that in the event of war he would try to maintain and preserve Irish neutrality. The extension of conscription in England raised the question of compulsory military service in Northern Ireland, and on May 2, 1939, De Valera protested against its application there. Two days later Chamberlain announced that Northern Ireland would continue to be exempted from conscription. When war came, De Valera at once announced that Ireland would continue its policy of neutrality. On Sept. 27 Sir John Maffey was appointed to the new position of United Kingdom representative in Eire.

World War II.—During the first phase of relative quiet, the Irish government was concerned chiefly with economic measures to meet the war situation and with the suppression of seditious activities by the I.R.A. In Jan. 1940 power was taken to intern persons suspected of activities against the state. But by May the need for serious national defense became apparent, and weekly conferences were arranged between the government and leaders of Fine Gael (United Ireland party) and Labour. All parties united in a recruiting rally in Dublin on June 16, and on June 29 Lord Craigavon, in response to urgent messages from Churchill and Franklin D. Roosevelt, promised co-operation with Eire for national defense. But the basis of co-operation was disputed, and De Valera announced on July 5 that Ireland must be both united and neutral. Craigavon then reported to the Northern Ireland parliament that De Valera had refused his offer of joint defense. On Nov. 7 De Valera again asserted that there could be no question of handing over ports in Eire as bases for Britain. His chief preoccupation, since the German occupation of France, had been the possibility of a German air-borne landing in Ireland, and Irish neutrality was jealously preserved to prevent any pretext for such attack. But in Jan. 1941 German bombs and magnetic mines were dropped near Dublin, and De Valera had to protest formally to Berlin. That same month it was made known that nine Irish ships had been sunk since the war began.

On April 13, in a broadcast, De Valera asserted that Eire would defend its neutrality by armed force. But in May the intention to apply conscription in Northern Ireland made him protest again, and on May 27 Churchill announced that it would not be applied. Four days later German bombers did serious damage in Dublin, but regrets and a promise of compensation were forthcoming from Berlin. A new situation arose after the United States entered the war in Dec. 1941; and while De Valera no longer feared invasion by either German or British forces, there was new pressure from the United States against his neutral policy. On Jan. 27, 1942, he protested strongly against the landing of U.S. troops in Northern Ireland, declaring that the Irish government had not been consulted; President Roosevelt replied by expressing amazement at the protest. On Feb. 3 De Valera appealed for the enrollment of an Irish army of 250,000 men "to maintain Eire's liberty." But the U.S. forces in Northern Ireland had been rapidly increasing, and on July 1 it was revealed that the United States had built a powerful naval base at Derry.

Lord Craigavon had died in Nov. 1940 and been succeeded as prime minister of Northern Ireland by J. M. Andrews. Andrews resigned in May 1943, and Sir Basil Brooke replaced him. In June, De Valera decided to appeal for a new mandate, and in the general election he lost his former clear majority, returning with only 67 seats. Cosgrave's Fine Gael also lost seats, and Labour came back with 17, while the Farmers and independents together had 22. But De Valera was re-elected prime minister in July, and in November he was still insisting that Eire should remain neutral. In Jan. 1944 Cosgrave retired from leadership of the chief opposition party and was replaced by Gen. Richard Mulcahy.

Pressure from the United States increased while preparations for the landings in Normandy were progressing. In March 1944, De Valera rejected a formal request by the United States for the removal of axis consular and diplomatic representatives from Eire "because their presence constituted danger to the lives of American soldiers and the success of Allied military operations." The British government then immediately suspended, for military reasons of paramount importance, all travel between Britain and Eire or Northern Ireland. But De Valera's neutral policy and his firmness in resisting pressures still commanded general support in Eire. A defeat in the *dáil* on the Transport bill gave him a pretext for holding another election, and he was returned with 76 seats and a majority of 14 over all other parties. On June 9 he was re-elected prime minister by 81 votes to 37.

His government was thus securely in office during the closing phase of the war. On May 13, 1945, Churchill in his victory broadcast made reference to the difficulties which had resulted from surrender of the Irish ports, and asserted that if necessity had arisen they would have been seized by the British navy. De Valera replied on May 16 with remarkable restraint, declaring that Churchill had, by resisting that temptation, advanced the cause of international morality. With the restoration of peace, Eire quickly attracted an immense number of visitors from England, and relations were entirely friendly. A new president was needed when Douglas Hyde's term expired in June, and Sean T. O'Kelly, one of De Valera's principal ministers, was elected by 565,000 votes to 453,000 for the Fine Gael candidate. In July De Valera declared in the *dáil* that Eire had been in effect a republic since the new constitution became operative in Dec. 1937.

Postwar Prosperity.—In supplying food and other exports to Britain during the war years, Eire had accumulated large sterling assets. The postwar influx of English visitors, who came eager to enjoy the abundant supplies of food, clothing and other rationed goods, added to these favourable balances. The country's new prosperity was reflected in the budget of May 1946, which reduced income tax by 1*s.* in the pound. There was a wave of inflation with prices rising fast, while trade required abnormally large purchases to replace stocks and to buy goods which had been unobtainable for years. Tourist development soon became one of the principal sources of income to meet the cost of such necessary imports. In 1947 tourism was estimated to have earned nearly £30,000,000, and forecasts by the travel organizations predicted that Ireland would soon rank next after France and England in tourist earnings. But this sudden influx of visitors, combined with heavy expenditure on capital and consumption goods, was producing serious problems. In Sept. 1947 De Valera went to London for talks on trade and finance with Prime Minister Clement Attlee and Sir Stafford Cripps. A restless spirit was growing in Ireland, after De Valera had been continuously in office for 15 years. A new party, Clann na Poblachta, formed by Seán MacBride, appealed specially to the new generation and to those who were tired of the old party rivalries. At two by-elections at the end of 1947 it presented its first candidates and won both seats. De Valera had threatened to appeal to the country if he were defeated, and in Feb. 1948 a new general election resulted in his resignation. His party was still by far the largest in the *dáil*, but the other groups combined unexpectedly under a new leader.

Interparty Government.—In the 13th *dáil* the number of members had been increased, by a redistribution of seats, from 138 to 147. De Valera refused to enter into any coalition with other parties, though his Fianna Fáil (Republican party) had won 68 seats and Mulcahy's Fine Gael had only 31. Labour's forces were split, with 14 seats held for the Labour party led by W.

Norton and 5 for National Labour. There were now 13 independents, among whom the ablest figure was James Dillon, who had been the only active advocate of Ireland's participation in the war. MacBride's new party, Clann na Poblachta, had put forward many candidates but won only nine seats. The Farmers' party held seven more. It was obvious that De Valera could easily form a coalition with a few of the smaller groups, but he refused all such approaches. Since Cosgrave's retirement, there had been no Fine Gael leader who commanded general support, and Mulcahy soon agreed to make way for any new leader who did not arouse hostile memories.

Urgent consultations with the independents and with MacBride's party resulted in agreement to combine under a new leader, John A. Costello. He had been attorney general and had close experience of imperial and international conferences, but with a large legal practice he had taken little part in political controversy. The desire for a change of government was especially strong among younger persons, who felt themselves excluded from all opportunity so long as De Valera kept his older colleagues in office. It was agreed quickly that an interparty government should be formed under Costello, without any formal coalition and with each party free to press for its own program. On that basis Costello secured 75 votes, after De Valera's nomination as prime minister had been outvoted, and the interparty ministry took office, with promises of reducing extravagant expenditure.

During the general election there had been little difference between the rival programs except that Costello's Fine Gael had openly declared its support for close relations with the British Commonwealth. MacBride's new party was regarded as the most adventurous, with its demand for a separate Irish currency and for an active policy to end partition. MacBride became minister for external affairs and his young colleague Noel Browne became minister for public health. McGilligan, the ablest survivor of Cosgrave's former team, became finance minister. Dillon, as the most important independent, took charge of agriculture. William Norton, the Labour leader, became deputy prime minister. But Costello's inexperience of leadership, which he had never desired, was soon reflected in nervousness about De Valera's intentions for the future. After 15 years in office he undertook a world tour, and his speeches in the United States, India and Australia suggested that he would revive the fuller demand for national independence and for ending partition. His prestige outside Ireland was so evident that Costello found it advisable to undertake a similar mission overseas, and he accepted an invitation to visit Canada in August. Until his departure there had been no rumour of any impending constitutional change. But in Montreal on Sept. 1 Costello made his first declaration of his new policy. After reviewing the constitutional developments in Ireland since the treaty of 1921 and the progressive stages of national independence, he claimed that Ireland's sovereignty was no longer in doubt but that the question arose whether the existing constitution was in a form "compatible with our national sentiment and historical tradition." It was plain that the new government proposed to forestall any intention by De Valera of demanding full independence as a republic.

On Nov. 17 Costello introduced in the *dáil* the Republic of Ireland bill, which proclaimed secession of the 26 Irish counties from the commonwealth and empowered the Irish president to exercise all functions concerning external affairs previously exercised by the British crown. The state was to be the Republic of Ireland, but the name "Eire" or "Ireland" would continue to be used. While the bill was in preparation urgent talks were held on Nov. 15 between Irish ministers and British and commonwealth leaders. MacBride then announced that as from Jan. 1949 there would be in Britain three categories of citizens: British, commonwealth and Irish. Attlee conferred with Sir Basil Brooke, the Ulster premier, and insisted that no change affecting the constitutional position of Northern Ireland be made without the consent of its people. Costello in introducing the bill proclaimed that it was "conceived in no spirit of hostility to the British people or the institution of the British Crown." He believed it would produce greater friendship between Great Britain and Ireland. The bill was not opposed at any stage and became law on Dec. 21. De Velera expressed his cordial support, regretting only that effective jurisdiction for the republic over the whole of Ireland could not yet be claimed.

The British government had shown its desire to assist in overcoming difficulties by declaring that Irish nationals would not be regarded as foreigners. But consequential legislation was necessary, and the Northern Ireland ministers pressed for new assurances in London. Brooke held a general election in Northern Ireland on Feb. 10, 1949, which produced an emphatic verdict for retaining the British connection. Labour lost 3 seats, and the Unionists now held 37 out of 52. But MacBride on Feb. 26 asserted again that Eire would not consider joining the North Atlantic treaty unless partition were first abolished. On April 17 the Irish republic was formally proclaimed in the Irish cities, and messages of good will were sent from King George VI and from Pres. Harry S. Truman. But in May Prime Minister Clement Attlee introduced the Ireland bill to provide for consequential changes. It expressly "recognised and declared that the part of Ireland heretofore known as Eire ceased to be part of His Majesty's Dominions" as from April 18, but clause (*b*) declared "that Northern Ireland remains part of His Majesty's Dominions and of the United Kingdom" and affirmed that "in no event will Northern Ireland or any part thereof cease to be part of His Majesty's Dominions and of the United Kingdom without the consent of the Parliament of Northern Ireland." This clause provoked great indignation in Ireland, as being a claim that the six counties should be permanently excluded from jurisdiction of the Irish parliament; whereas the Government of Ireland act of 1920, as well as the treaty of 1921, had contained provisions for united control. Large public meetings of protest were held in Ireland, and on May 10 the *dáil* unanimously voted a resolution by Costello protesting against the Ireland act. (The secession of Ireland from the commonwealth is discussed in COMMONWEALTH OF NATIONS.)

Within its first year Costello's government had thus unexpectedly severed relations with the commonwealth and apparently left less ground than ever for difference among the principal Irish parties. Partition remained the chief outstanding problem, but the cleavage with the Ulster parliament had been deepened by secession. With no clearly defined program, the interparty government was soon weakened by the competing claims of its component groups. Public expenditure rose rapidly to meet such demands, and heavy purchases to replace exhausted stocks were depleting the large sterling assets that had been accumulated during World War II. Ireland had obtained inclusion in the benefits of the European Recovery program to assist agricultural production. Dillon's ambitious scheme for land reclamation with U.S. aid promised big results over a long period; but his first success in increasing Irish exports of eggs and butter to England was not maintained when export prices fell, and the cost of imported fertilizers and maize (corn) was increased by the sudden devaluation of sterling. Internal discords in the ministry reached a crisis over Noel Browne's plan for free public health services under state control, which was strongly opposed by the Catholic bishops. Costello then repudiated Browne's proposals, and his narrow majority in the *dáil* was at once shaken.

The Elections of 1951, 1954 and 1957.—In May 1951 a general election was held, to clear the air. The new *dáil* that resulted scarcely differed in composition from the previous one, the interparty groups retaining 78 seats and Fianna Fáil gaining one, which brought its total to 69. MacBride's new party, however, had been split by a bitter feud with Browne, and some of the independents withdrew their support from Costello. De Valera then, though still refusing to enter any grouping, won promises of support outside his own party and was elected prime minister by 74 votes against 69. Taking office in June, he declared that the republic would continue to stand aloof from the Commonwealth of Nations and pursue a policy of neutrality. His ministry consisted almost entirely of his former colleagues, with hardly any attempt to enroll younger members; and in April 1954, by which time his party had been defeated in four out of five by-elections since 1952, he decided to dissolve the *dáil*. In the ensuing general election (May 1954), only 65 seats went to Fianna Fáil. On June 2, there-

fore, though Fine Gael had only 50 seats, Costello was elected prime minister by the interparty grouping, which gave him 79 votes against 66.

This second experiment in interparty government soon showed once more the difficulty of producing a coherent policy, while each of the smaller parties was liable to threaten secession if its special demands were not met. The new government's authority was, moreover, challenged by the increasing frequency of I.R.A. raids on British barracks and other posts in Northern Ireland. In Aug. 1955 there was a successful raid on Arborfield camp in England and arms and ammunition were stolen. Costello insisted vehemently that the final authority of the Irish nation resided in the *dáil*. The raids continued and produced embarrassing demonstrations of sympathy in Ireland with the raiders, where a more responsible attitude had been expected. Meanwhile economic conditions became unstable; although there was a budget surplus, a continual rise in imports threatened the national economy. The government imposed new import duties, ranging from 37½% to 5%, on some 70 commodities in March 1956 and also enforced restrictions on hire purchase (installment buying) to discourage private spending. In July similar duties were imposed on a further 100 items. Emigration, chiefly to Great Britain, had been growing steadily and the census reports showed a total emigration of over 200,000 in the previous five years, which was higher than at any time since the late 19th century. The population of the republic had declined to the lowest level yet recorded of 2,898,300.

Meanwhile the Labour party had gained courage from the successful reunion of the Congress of Irish Unions and the Irish Trade Union congress, after a split of 11 years. This reunion of some 400,000 members in more than 80 unions encouraged the Labour party to adopt a more independent attitude within the interparty government. MacBride, as leader of the small and diminished Clann na Poblachta, which had caused the collapse of the first coalition, had declined Costello's offer of a cabinet post in his second ministry. He was widely regarded as having contacts and sympathy with the I.R.A. and in Jan. 1957 he moved a vote of no confidence in the government, ostensibly in protest against its economic policies. Costello anticipated this conflict by dissolving the *dáil* on Feb. 12 and a general election followed on March 5. Labour refused to continue in the previous interparty front and each party put forward its own candidates.

This gave De Valera a clear advantage in claiming that only a strong and united party could provide effective government. His Fianna Fáil party gained 13 seats and an overall majority of 9 by winning 78 seats in the new *dáil*. Costello's Fine Gael party lost 9 seats and Labour lost 7, retaining 40 and 12 seats respectively. MacBride lost his own seat and only one of his Clann na Poblachta party was returned. Sinn Fein, however, by winning 4 seats, showed the extent of its support in certain counties, although its members refused to take their seats in the *dáil*, thus increasing De Valera's majority. The I.R.A. raids on the Ulster borders had become so defiant by July that De Valera invoked the Offences Against The State (Amendment) act of 1940 which authorized the internment of persons suspected of being concerned in illegal organizations. An internment camp was opened immediately at Curragh, county Kildare, where more than 100 young men were confined after arrest, including the entire national executive of Sinn Fein. De Valera then declared openly that force could not provide a solution of the problem of Irish partition. "Force," he said, "could not be successful, and it could in fact be disastrous, leaving behind a situation more embittered and uncertain than the present."

Notwithstanding these efforts to restore order, the I.R.A. raids continued at intervals in 1958. A new situation was imminent because of De Valera's personal difficulties in continuing as *taoiseach* (prime minister) because of increasing blindness and advancing years. Séan O'Kelly's second term of office as president of the republic was due to expire in June 1959 and De Valera's name was widely discussed as his successor. It was generally assumed, when he suddenly proposed the return to the British system of single-member constituencies, thereby abolishing proportional representation, that De Valera believed it would improve the prospects of Fianna Fáil when he retired from active leadership. This proposal provoked a growing tide of opposition in which the Labour party ultimately played a decisive part by organizing resistance to it. Meanwhile De Valera agreed to accept nomination for the presidency, though it was not offered to him without a contest. A referendum was held in June 1959 on two separate questions: the proposal to abolish proportional representation, and the election of a new president. The opposition groups mustered 417,482 votes for their candidate, Gen. Séan MacEoin, but De Valera was elected president with 538,058 votes on June 17. He was installed as president on June 25, having completed almost 50 years of active political leadership.

Lemass in Office.—Séan Lemass, his chosen successor, replaced De Valera immediately as *taoiseach*, having spent some years as minister for industry and commerce. This change of leadership was followed in the other principal parties. Gen. Richard Mulcahy resigned the leadership of Fine Gael and John Costello resigned as leader of the opposition. Both posts were filled by James Dillon, a contemporary of Lemass; while William Norton was replaced as Labour party leader by a much younger successor, Brendan Corish. Thus the older leaders who had dominated Irish politics for 40 years all retired in 1959, leaving a new situation in which Lemass and Dillon each brought new vitality to their parties, coupled with prestige, experience and notable gifts for public life. Lemass, who had for years been absorbed in the economic aspects of Irish revival, declared at once that he desired closer Anglo-Irish trade relations. He insisted also that the approach to reunion with Northern Ireland must be through consent on both sides. Dillon, with more flamboyant gifts of oratory and a long family tradition of patriotic service, had never disguised his desire to modify the obligations which had been imposed by the long efforts to enforce a revival of the Irish language. He relied on strengthening Irish agriculture, rather than developing new industries, to stop the drain of emigration and to raise the standard of living.

The first year of the new alignment produced little open conflict between the parties, while all were preparing the ground for the next elections. The most striking events of 1960 arose from the prominent part given to the Irish republic in the work of the U.N. The Irish permanent delegate, Frederick Boland, was chosen president of the assembly for the year and showed great ability and good humour in controlling the turbulent scenes which Khrushchev provoked in the assembly in New York. In the Congo operations also, the Irish military contingent gained distinction; two battalions were sent to form part of the international force organized by the U.N. A third battalion then replaced the first two and the Irish army's Gen. Séan MacEoin was appointed commander of all the international forces in the Congo.

In Oct. 1961 elections for the *dáil*, the Fianna Fáil lost its absolute majority (70 seats instead of 78) whereas the Fine Gael increased its members from 40 to 47 and Labour from 12 to 16. Lemass, who had dissolved the 16th *dáil* expressly to obtain a mandate for membership of the European Common Market, was re-nominated prime minister.

In 1962 the I.R.A. formally called off its campaign of violence as the means to enforce unification.

II. POPULATION

In 1961 the population of the Republic of Ireland was 2,814,703, a decrease of 2.9% since 1956 when it was 2,898,264. Between 1900 and 1961 the total population declined by about 10%. Estimated net emigration during the intercensal period 1956–61 was 215,641; the number of births exceeded the number of deaths by 132,080 whereas the total population declined by 83,561. A high proportion of the emigrants were women; the number of females per 1,000 males of the population was 989 in 1961, one of the lowest ratios in the world. Until World War I Irish emigration was directed mainly toward the United States, but after 1914 the flow was chiefly to Great Britain and of these a considerable number returned home permanently after an absence of some years.

The largest towns are Dublin, the capital, Cork, Dun Laoghaire, Limerick and Waterford (*qq.v.*). Towns with populations of over 10,000 are Galway, Dundalk, Drogheda, Sligo, Bray, Wexford,

Area and Population of the Republic of Ireland

Kilkenny, Tralee, Clonmel and Athlone.

The official languages of the republic are Irish (*see* CELTIC LANGUAGES) and English. The number who stated that they could speak Irish (Gaelic) in 1946 was 589,000, compared with 667,000 in 1936. Of these, 105,000 were in the Gaeltacht (Gaelic-speaking) districts, 83,000 in the districts which are partly Gaelic-speaking and 396,000 in the rest of the country. The teaching of Irish is an important feature of the educational system, and a knowledge of the language has gradually been made compulsory for most examinations. Enthusiasm for the language revival has, however, abated since the achievement of independence from Great Britain.

III. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—The 1937 constitution that replaced the original constitution of the Irish Free State (enacted in 1922) shows three main influences: Irish nationalism; English and Free State parliamentary traditions; and Catholic philosophy.

The preamble of the constitution invokes the Holy Trinity and, acknowledging the dependence of the people of the Republic of Ireland, declares that the purpose of the constitution is the promotion of "the common good, with due observance of prudence, justice and charity, so that the dignity and freedom of the individual may be assured, true social order attained, the unity of our country restored, and concord established with other nations."

The constitution declares the Irish republic to be a democratic state, sovereign and independent. The head of the state is the president (*Uachtaran na hÉireann*), who is elected for seven years by the direct vote of all citizens. Nominations are made by members of the *oireachtas* (parliament) or of the county councils. The president appoints the prime minister (*taoiseach*) on the nomination of the *dáil*, and on the nomination of the prime minister and with the previous approval of the *dáil* he appoints the other members of the government. He signs and promulgates laws. He can refer certain bills to the supreme court to test their constitutionality. He also has power to refer certain bills to a popular referendum upon petition of a prescribed percentage of the *dáil* membership. He is supreme commander of the armed forces. The president is advised by a council of state consisting of former presidents, former and incumbent prime ministers and chief justices, as well as of others, some of whom he may name.

The *oireachtas* consists of the president and two houses. The house of representatives (*dáil éireann*) consists of 144 members elected by adult suffrage under a system of proportional representation. The government, which consists of from 7 to 15 members, is responsible to the *dáil*. The maximum term of the *dáil* is seven years. The *dáil* alone can initiate money bills, and the *seanad éireann* (senate) may only make recommendations on them. *Seanad éireann*, an unsuccessful attempt to create a vocational chamber, is composed of 11 members nominated by the prime minister and 49 members who are elected by the *dáil* and the county councils from panels representative of the universities, culture and education, labour, industry and public administration and social services. The system of proportional representation is used in the election of a *seanad*, which has to take place within 90 days after a dissolution of the *dáil*. The *seanad* cannot veto legislative proposals and has but 90 days for the consideration or amendment of bills passed by the *dáil*.

The constitution recognizes the family as the unit of society with rights superior to all positive law. Divorce is practically forbidden. Private property is recognized as a natural right of man, but this and other personal rights may be limited by law out of consideration for the common good.

An interesting feature of the constitution is the enumeration of directive principles of social policy. The courts may not take cognizance of them in determining the application of laws. The principles, intended for the guidance of the *oireachtas*, include the right of every citizen to a decent livelihood, the establishment of families in economic security on the land, and the regulation of credit and of the distribution of property in the interests of the common good.

For the first three years after its establishment the constitution was amendable by ordinary legislation. Thereafter a popular referendum was necessary.

Local Government.—The Irish provinces, Leinster, Munster, Connaught and part of Ulster are no longer political divisions. They are subdivided into 27 administrative counties (*see* Table) and the four county boroughs of Dublin (*q.v.*), Cork, Waterford and Limerick. The department of local government supervises local affairs through the county councils, county boroughs and urban district councils. These bodies, elected by popular vote, have a system of local government combining a council with a manager; they are responsible for maintaining roads, water supply, sanitation, etc., and have authority to levy local rates.

Religion.—Under article 44 of the constitution, the special position of the Roman Catholic Church was recognized "as the guardian of the Faith professed by the great majority of the citizens"; recognition was also given to the Church of Ireland, the Presbyterian Church, the Methodist Church, the Religious Society of Friends, the Jewish congregations and "the other religious denominations existing in Ireland at the date of coming into operation of the Constitution." "Freedom of conscience and the free profession and practice of religion are, subject to public order and morality, guaranteed to every citizen." The state guaranteed not to endow any religion and not to impose any disabilities or make any discrimination on the ground of religious profession, belief or status. According to the 1946 census the number of persons of each religion in the republic was: Roman Catholics, 2,786,033; Protestant Episcopalians, 124,829; Presbyterians, 23,870; Methodists, 8,355; Jews, 3,907; Baptists, 462; others, 7,651.

External Relations.—An important change affecting the relations of the Free State with the Commonwealth of Nations occurred when Edward VIII abdicated on Dec. 11, 1936. An act was passed to remove from the constitution all reference to the king and to abolish the office of governor general. The Executive Authority (External Relations) act of Dec. 11, 1936, accepted the abdication of Edward VIII. It also provided that executive authority, which it vested in the Free State executive council, could, in certain circumstances, be exercised for the appointment of diplomatic representatives and conclusion of international agreements by the king. The king had ceased to be head of the state, but, by virtue of his recognition as the hereditary symbol of commonwealth co-operation, he might, on the advice of the Free State executive council, exercise certain powers concerning external relations. The new constitution enacted in 1937 did not alter the operation of these

provisions. Diplomatic representatives continued to be appointed by the king when advised by the Irish government, and the credentials of foreign diplomats accredited to Ireland were addressed to the king.

The Executive Authority (External Relations) act, 1936, was repealed by the Costello government in 1948 when the Republic of Ireland act was passed. Under this act the exercise of executive powers concerning external relations was transferred to the president acting on the advice of the government. The description of the state was declared to be the Republic of Ireland, but in accordance with the constitution, which was not affected by the act, the name of the state remained Ireland. The aim of the act was to clarify the constitutional position and to terminate association with the commonwealth. This aim was accepted by the commonwealth countries. The Ireland act, 1949, which was enacted by the British parliament, declared that from April 18, 1949, the state had ceased to be a British dominion; it did not, however, become a foreign country so far as British statutes were concerned, and its citizens did not become aliens in Great Britain. Australia, New Zealand, South Africa, Canada and Southern Rhodesia adopted legislation declaring Irish citizens to have the same rights and obligations as their own citizens.

2. Political Parties.—Since the establishment of Irish national government in 1922, the principal single party, Fianna Fáil (Republican party, also known as Party of Destiny), has been dominated by Eamon De Valera's leadership. The main difference between the Fianna Fáil and its rival Fine Gael (United Ireland party) has concerned Anglo-Irish relations, De Valera seeking to break the connection with England and pursuing a program of economic self sufficiency for Ireland by developing new industries. When De Valera's long tenure of office was broken in 1948 by John A. Costello's coalition government, which was expected to seek closer ties with the Commonwealth of Nations, Costello suddenly declared a republic in order to forestall any campaign for that purpose. Since that sudden departure, there has been no clear line of division between the two main parties, though Fianna Fáil attaches special importance to the revival of the Irish language. Both parties have sought cordial relations with Britain and both have approved Ireland's application for membership in the European Common Market. The Labour party has on a few occasions shown its capacity to cut across party lines but its strength has varied from 22 to 13 seats. Other small parties such as the Clann na Talmhan (Farmers' party) and independents have always won some seats; Sean MacBride's Clann na Poblachta (New Republicans), formed in 1947 with a policy to end partition and to found a separate Irish currency, made a strong appeal to young voters in 1948 but held only one seat nine years later.

3. Trade Unions.—With about 600,000 employees in the republic, excluding those in agriculture, about 330,000 are members of trade unions. There are over 100 unions, many of which have less than 1,000 members, but the Irish Transport and General Workers' union, which aims at including all trades in one big union, claims 150,000 members. About one-fifth of all trade unionists are nonmanual workers. For years there was acute rivalry and overlapping between the definitely Irish unions and the branches of British unions and this resulted in the formation of two separate organizations, the Irish Trade Union congress and the Congress of Irish unions. Negotiations and trade union policy were gravely hampered by this duplication, and in 1959 the two congresses were fused in the present Irish Congress of Trade unions which attempts to overcome the former difficulties. Irish unions, though allegedly fully independent of British unions, are in fact frequently subject to pressure when crises arise in Britain. Employers' unions in Ireland are few and are combined in the Federated Union of Employers which has its separate industrial sections and regional branches.

To supervise relations between workers and employers there are in some industries permanent joint negotiating bodies. Collective agreements usually determine wages, working hours and other labour relations. The Labour court was set up in 1946, consisting of five members, all appointed by the minister for industry and commerce. Its function is conciliation; it can summon witnesses on oath and require the production of documents, but it cannot enforce its directions or impose penalties. It usually acts on invitation during a dispute, but it often appoints an official conciliation officer to mediate before intervening directly.

4. Employment and Housing.—As a consequence of persistent efforts to create new industries with a general aim of economic self sufficiency, the workers employed in manufacture and construction have risen from about 159,000 in the mid-1920s to more than 265,000 in the early 1960s; while workers in agriculture, forestry and fishing have declined steadily from about 650,000 to less than 450,000—the decline has averaged 10,000 a year since 1951. Low wages in agriculture, and the lack of any attractive prospect on smaller farms, have been the main factors in causing emigration. Unemployment statistics show a favourable trend, falling from 8.6 of insured persons in 1941 to 5.7 in 1961. Wages have continued to rise, from a base of 100 in 1953 to 142 in Dec. 1960; agricultural wages rose in the same period from 100 to 118.

With postwar construction of many houses of modern type there has been a general improvement in housing standards. Grants are paid by the state to local authorities, public utility services and private persons for building and reconstructing houses.

5. Health and Welfare Services.—The comprehensive organization of social services began with the Irish Poor Relief act of 1838, which divided the country into poor-law unions and created the workhouse system of relief. In 1923 home assistance was substituted for workhouse relief. In 1851 free medical attendance became available for the sick poor in their homes or in dispensaries. Health services are now organized and directed by county medical officers. Grants from the Hospitals Trust fund, financed by the Irish Sweepstakes, provide a regular income for the building, reconstruction and repair of hospitals and dispensaries. Public hospitals provide treatment free or at a charge graduated according to means. For tuberculosis and some other diseases examination and treatment are free, and cash allowances are paid, in certain circumstances, to patients who are prevented by their illness from providing for their own maintenance and that of their dependents. The Social Welfare act of 1952 introduced a co-ordinated system of social insurance, superseding the previous national health, unemployment, and widows and pensions schemes. Under this act, social insurance is compulsory for all employed persons between 16 and 70, with the exception of certain categories. Manual workers in the building trade may be insured against the loss of employment resulting from bad weather.

6. Justice.—Law enforcement is the responsibility of the ministry of justice which also controls the police (*garda siochana*). Judges are appointed by the president on the advice of the government; they retire on pension at the age of 70. They are independent of the executive in the exercise of their judicial functions and are subject only to the constitution and the law.

There are four courts: the district court has civil jurisdiction up to £50 and minor criminal jurisdiction; the circuit court has civil jurisdiction up to £600 in contract and tort and £2,000 in equity (unlimited jurisdiction with the parties' consent) and extended criminal jurisdiction, and acts as a court of appeal for the district court; the high court has unlimited jurisdiction in civil and criminal cases and acts as a court of appeal for the circuit court; the supreme court acts as a court of appeal for the high court.

7. Education.—Elementary education, which is given in national schools, is free. Since 1922 the Irish language has been an essential feature of the curriculum in state-aided schools, and there is insistence on the desirability of teaching classes, so far as is practicable, through the medium of Irish. Attendance at some schools is compulsory for children between the ages of 6 and 14 years, and more than 40% of children between 14 and 16 years attend voluntarily, either in elementary or in other schools. The number of national schools in the early 1960s exceeded 4,800, representing a decrease of about 1,000 since the 1920s. Of the total number of teachers two-thirds are women.

Secondary education is given in private schools which, in many cases, are conducted by Catholic religious orders. Where state grants are paid, as is the general rule, the schools are open to inspection. In contrast with the falling numbers of pupils in

elementary schools, the number of pupils attending recognized secondary schools has more than doubled since the 1920s. There were about 500 recognized secondary schools in the early 1960s in about half of which instruction was either entirely or partly in Irish.

Vocational schools in cities, towns and some rural areas provide continuation and technical education. They are maintained partly from the rates (local taxes) and partly from state grants. There were about 90,000 students, nearly three-quarters of whom were over 16, in the early 1960s. Agricultural and veterinary education is provided in institutions managed either by the department of agriculture or by religious orders. Short courses in agricultural instruction are also organized locally by statutory county committees which receive grants from public funds. Higher agricultural education is given by the universities.

The oldest university in Ireland, the University of Dublin (Trinity college), was founded in 1591. The National University of Ireland, founded in 1909, has constituent colleges in Dublin, Cork and Galway and treats St. Patrick's college (1795), Maynooth, as a recognized college. University education is financed partly from state grants.

8. Defense.—The supreme command of the defense forces is vested in the president. The minister of defense is assisted by a council of defense consisting of the minister, his parliamentary secretary, the chief of staff, the adjutant general, the quartermaster general and the permanent secretary of the department of defense. The establishment provides for a permanent force of just under 13,000 officers and men, including the air corps and naval services. The reserve defense force (first and second line) numbers about 20,000 men. The first-line reserve is composed of officers and men who have already been trained during service in the permanent force. There is no compulsory military service. Minimum service is two years' permanent enlistment and six years in the reserve.

(D. G.)

IV. THE ECONOMY

A century ago Ireland depended mainly on agriculture, though there was already a growing linen industry in the northeast round Belfast; this area, now within the Six Counties, became the main industrial district of Ireland. From the foundation of the Irish Free State, industrial expansion was desired as a means of strengthening the national economy and of providing work for those who might otherwise leave as emigrants. There are considerable differences of opinion on the methods of achieving industrialization. The first clear effort in the 1920s was to develop home supplies of fuel and power through electrification, but from 1932, when the Fianna Fáil party under De Valera came to power, further legislation and loans resulted in an increase of industry and its widespread distribution over the country. This policy received some sharp criticism as economically unsound, especially in the case of assembly industries which depended on the import of manufactured parts: many British cars, for example, were conveyed to a port and, to qualify for the lower rate of taxation on Irish-assembled cars, were taken to bits, shipped across the Irish sea, and put together again.

Accurate assessment of the resources of Ireland has not always been a characteristic of publicists. Since the early 19th century the search for minerals has been pursued with considerable zeal, but the resources of coal and iron ore are slight and the deposits of other minerals, such as copper and lead, are inadequate for the support of any major metalliferous industry. In the earlier part of the 19th century, copper, lead and zinc were mined at various places in Ireland for export to Britain, but when overseas supplies became available at lower prices practically all the mineral workings ceased, though a few have been revived from time to time. Far more has been achieved in the provision of power, based on the harnessing of rivers, the successful use of peat after a long period of research, the allocation of the coal reserves at Arigna (County Roscommon) to a generating station, and the maintenance of plants at Dublin and Cork able to use imported fuel. In the 1920s it was feared that the power would not be adequately used, but the domestic and farm use has increased beyond all expectations and added to the amenities of life both in towns and in rural areas, where supply lines have been carried along remote country lanes to scattered farmsteads. A main purpose of electrification has been to encourage industrialization not only in Dublin and other ports but also in country towns to reduce emigration from the rural areas. Although a number of factories have been successfully established in quiet country towns, the emigration remains heavy and in the 1960s showed no sign of diminishing.

The only basic natural resource of the republic is land, which might indeed be regarded as the only permanent source of wealth. Though a distinction is commonly drawn between agriculture and industry, it is rightly said that agriculture is itself an industry, especially as methods become more and more scientific through the selective breeding of stock, the raising of new and improved strains of seed and the application of chemical fertilizers to soils. The use of modern machinery on the farm has made possible the reduction of manpower on the land, *e.g.*, by the installation of milking machinery and the increasing use of tractors. Since the 1880s co-operative creameries have been established in a belt of country extending from north Kerry through the counties of Limerick, Cork and Tipperary into Kilkenny, Waterford and Wexford, and also in the three Ulster counties of the republic, Donegal, Cavan and Monaghan. The advocates of creameries have never achieved their aim of making milk production with butter manufacture the main purpose of Irish farming, partly because on many of the small farms so few cows are kept that a regular daily milk supply cannot be guaranteed to the creameries. Within a radius of 60–70 mi. from Dublin much of the milk is sent to the large city milk suppliers, and in the summer their demand is increased by the tourist inflow and the large sales of ice cream. In much of the country stock raising remains the chief resource, with the meat markets of the cities or the export of live animals as the eventual source of profit. Traditionally, young animals are sold at fairs to farmers or dealers who take them on to richer pastures on larger farms, but as a system of buying and selling the fair is somewhat archaic and in some provincial towns, as in Dublin, auction marts have been established.

By the early 1960s efforts to establish a meat canning industry had had only a limited success. Equally, the production of bacon, though possessing a tradition of efficiency since the early 19th century, has not expanded to any significant extent: pig-keeping on Irish farms has been subject to sharp fluctuations and there has been only a small export of bacon in most years since World War II. Derivatives of the dairy industry, such as condensed milk, cream and cheese, have not achieved a significant place in the international market. Other agricultural staples include grains and flax, but the latter is hardly grown at all now, though it was in great demand by the Northern Ireland linen producers during World War II when overseas supplies were limited. The republic's policy has been to encourage the growth of wheat rather than to rely on imports. Barley is grown to supply malt to the breweries and distilleries.

1. Agriculture.—Before World War II the agricultural output was absorbed equally into three channels: the households and stock; supply of the home market; and export trade. During the war the exports declined to almost one-fifth, with the rest of the output shared about equally between the farms and the home market. Since 1945 the prewar division has appeared again.

Approximately two-thirds of the republic (11,796,300 ac.) is improved farmland; the remaining third consists of areas built up or used for some other nonagricultural purpose, of forests and woods, or of rough pasture, most of which is used for pasturing sheep and even cattle in some areas. In the early 1960s more than 600 sq.mi. owned by the forestry division of the department of lands had been planted. Of the improved farmland more than two-thirds is permanent pasture and over half the rest is in hay: hardly one-sixth, therefore, is under cereal, root and green crops. An increase in cropping is generally regarded as desirable, but though this was achieved during World War II under compulsory tillage legislation, virtually all the land then newly plowed was returned to grass afterward. Similarly more fruit trees, vegetables and other market gardening produce could be grown, as some suc-

cessful experiments have shown, *e.g.*, a jam-making firm near Dublin has established fruit farms and German farmers near Killarney have transformed some old pasture lands into orchards and fruit gardens.

Crops.—About one-tenth of the improved land is used for cereals, mainly wheat, oats and barley. Very little rye is grown, although it is a traditional crop in the west where rye straw is still used for thatching. This craft, however, is declining and slates or tiles are increasingly used as roofing materials.

Cereal cultivation has been encouraged since 1932 by bounties and by restrictions on certain imported foodstuffs. In 1932 there were only 21,000 ac. of wheat, but this increased to 255,000 ac. by 1939 and 662,000 ac. in 1944, when compulsory tillage legislation was in force. After 1945 the wheat acreage declined, but remained considerably higher than before World War II. By contrast very little wheat is grown in Northern Ireland, which relies on imported supplies. Oats and barley are traditional cereal crops in Ireland, subject to less fluctuation in area than wheat; the cereal crops are mainly sold to the mills, in many cases through agents in country towns, not unusually the grocers.

Root crops include potatoes grown for foodstuffs and also for the farm stock, with a limited, though important, growth for seed. Potatoes can be grown successfully on many types of land, including areas recently cleared by peat cutting. Turnips, mangels and other root and green crops, including kale cabbage, are grown mainly as fodder, but sugar beet cultivation has been fostered to supply the factories at Carlow, Mallow, Tuam and Thurles.

Livestock.—The main aim of Irish farming is the support of livestock. The number of cattle fluctuates between 4,500,000 and 5,000,000, of which about one-quarter are milch cows and the rest dry stock intended for fattening or export as stores—though many animals are now sent out as fat cattle, almost all of them to Great Britain. Government legislation has done much to improve the breeds, especially by stationing "accredited bulls" throughout the land. Traditionally Ireland is an exporter of butter but this trade has declined since World War II, partly through competition from New Zealand, Australia and Denmark and partly through heavier local consumption. Over 4,000,000 sheep are kept for mutton and wool, both of which are exported. Most of the sheep are kept in the mountains, but there are many farms west of the Shannon, notably in the counties of Roscommon, Galway and Clare, where sheep are raised on limestone pastures which have excellent grasses. Dealers from Dublin visit the towns and collect sacks of wool from the farmers, or buy from local agents; in some towns dealers organize temporary wool markets.

Pigs and poultry are cash resources on many farms, but neither has been consistently successful as a source of income. During the war years the lack of maize (corn) meal reduced the pig population to one-third of the prewar average of 1,000,000, but since then the 1939 level has been reached again. For a long time poultry-keeping for both eggs and table birds was a main contributor to the financial stability of many farms, especially of the smaller ones. Up to 1939 there were 20,000,000 poultry on the farms, but since World War II the number has decreased by one-third because of the decline of the export trade through the success of the British poultry industry.

2. Agricultural Holdings.—The republic has about 315,000 holdings and 240,000 farmers: the statistical disparity is due to a variety of causes, including the possession of more than one holding and the inclusion of sports fields or park lands around houses, and also to the ownership or even actual working of the land by people who do not list farming as their main occupation. In some parts of the country farmers rent patches of land under the conacre system, whereby small portions of land are leased for a single crop or for pasture. Though tenants may rent the same conacre fields annually they never buy them outright. The farms fall into three groups: small, 1–30 ac.; medium-sized, 30–100 ac.; and large, over 100 ac. Small farms are most prevalent in the west, particularly in Donegal, much of Sligo, central and west Mayo and west Galway. They are also found in Leitrim, which is often regarded as almost the poorest county in Ireland, and they are numerous in the counties of Monaghan and Cavan. On many of these small farms there are patches of oats and potatoes with some meadowland and pasture, and the stock consists of one or more cows, some sheep and some poultry. In some western districts, however, there are mountain sheep also. Many holders of these small farms can hardly maintain any reasonable standard of living if they depend solely on the land: almost invariably other sources of income are available. Some men work as labourers on larger farms, in neighbouring towns, or on the roads, either seasonally or permanently; others cut peat (turf) from the bogs for sale; and many are helped by remittances from emigrants. Government measures for the improvement of the poorest areas include plans for the encouragement of fishing, tomato growing in Donegal and Galway, the organization of peat-cutting and the extension of rural industries.

Medium-sized farms cover most of the central lowland south of a line from Galway to Dundalk, and are equally prominent in the mountain-studded lowlands of the south. In parts of the lowland, especially in the east, there are also many larger farms, and everywhere small farms are found. Medium-sized farms are prevalent in Kerry, which never underwent the minute fragmentation of land that characterizes most of the western areas. These farms are generally worked by the farmer himself, possibly with some family help: few farms of less than 70 ac. can support full-time labourers. Characteristically, most of these farms are "mixed," with an output of wheat (except in the wetter, western areas), foodstuffs such as oats, and vegetables such as potatoes, turnips and mangels. Many of the farmers are able to change their production according to the circumstances: they are, for example, the main suppliers of the creameries in the south and on the Ulster borderland. It is they who have supported new enterprises such as growing of wheat and sugar beet. But their main economic resource is cattle, reared for sale at the monthly fairs in the country towns or at auction marts now in some places replacing fairs.

Barely one-tenth of the farms are of more than 100 ac. These are not confined to any one area of the country, though they are most frequent in the east, particularly in Counties Dublin, Kildare and Meath, where many of them are used almost entirely for grazing animals intended for the fat stock markets or for export. But they also include a number of holdings that have a mixed economy similar to that of the medium-sized farms, some large dairy farms of considerable prosperity, and some fine sheep farms near the mountains.

In the mid-19th century an Irish countryman's main ambition was to own land, and by the end of the century the slogan was the "Three F's": fixity of tenure, the free sale of the goodwill of a farm in the event of a change of tenant (known in Ireland as "tenant right," *i.e.*, tenant's interest), and a fair rent. By a series of legislative acts from 1870 onward, the land was transferred to the people who farmed it. At first progress was slow but from 1903, when the Wyndham act made 195,000 tenant farmers (in the present republic) into purchasers, it was relatively swift. But there are still sharp economic problems. In 1955 the Land commission estimated that three-quarters of all the holdings in the country, with an annual valuation of £20 or less, were uneconomic. This figure includes many patches of land that are not farms in the sense of holdings sufficient to support a family, yet it makes clear the need for consolidation of small parcels of land to provide farms of larger size. In fact, this is happening constantly, for small farms are frequently united by legacies to relatives rather than by sale.

Government loans are available for improvements on farms, including the building of farm houses and outpremises. In many areas there have been substantial changes, not least the assignment of old cottages to become farm buildings as they are replaced by new houses, most of which now have electricity. But the stability of Irish farming depends mainly on external trade, virtually all of it with Britain. In the British market, produce such as Irish bacon, cheese, butter and canned meat can be sold only in competition with the highly efficient continental and commonwealth producers.

3. Fishing.—Fishing was far more prosperous before World War II than in the 1960s, and according to official statistics only

about 6,000 men are now engaged in sea fishing, two-thirds of whom are only occasional fishermen, depending alternatively on small farms or some other part-time occupation for their livelihood. The catch of sea fish includes herring, whiting, mackerel, cod and haddock; shellfish, chiefly crayfish and lobsters, are caught off the west coast, largely for export. There are no large fishing communities, but rather a small industry at various points along the coast, for example at Burtonport (Donegal), Dingle (Kerry), and Kinsale (Cork), where a cannery has been built. With government assistance several freezing plants have been built at various places to foster sea fishing. Many of the rivers are famed for salmon fishing, notably the Moy, the Blackwater and the Shannon, which has a salmon hatchery and also an eel fishery; fishery work is done on the Erne, Lee, Liffey and Clady. As a sport, angling has long been popular; both river and lake fishing are tourist attractions. At Kinsale shark fishing has become an exotic sport for the few.

4. Minerals.—In Ireland minerals are of minor significance. Some coal is mined in the Castlecomer field and at Arigna, where it is used for a power station. Peat is cut for domestic fuel and for power stations. In the Vale of Avoca (Wicklow) copper pyrites are mined. Intermittently, copper, lead, iron and zinc have been mined but generally without commercial success, though the search for such minerals continues. In the early 1960s Canadian mining companies were investigating a deposit at Tynagh, in the southeast of County Galway, where copper, lead, silver and zinc have been found. Other Canadian companies are prospecting in a wide area of the west and south of Ireland.

5. Industry.—During the 19th century efforts were made to establish factories in various Irish towns, but many enterprises were unable to compete with British producers. Numerous woolen mills, for example, could not maintain themselves against those of Yorkshire, though a few making suitings of fine quality have survived in County Cork. After 1800 linen spinning and weaving became a factory industry in the northeast, and in the 1850s Ulster acquired two more of its famous industries, shipbuilding in Belfast and shirtmaking in Londonderry and district. Dublin was far less fortunate in its 19th-century economic history, and the major provincial towns such as Waterford, Cork, Limerick and Galway saw little industrial expansion and remained virtually stationary in population at the time when industrial towns were growing rapidly in Britain and in the northeast of Ireland. Nevertheless, there were numerous industries in the rest of Ireland, such as flour and general grain milling in many country towns. Most of the small mills were eventually closed and larger mills built in the major towns, though some remotely placed mills still survive, for example in County Donegal and County Sligo. The brewing and distilling trade was severely hit in the mid-19th century by the total abstinence campaign of Father Theobald Mathew, and many of the local breweries then closed were never re-opened. In time both brewing and distilling revived but were concentrated in a few great enterprises, mainly in Dublin and Cork, though there are also distilleries at Kilbeggan (Westmeath) and Tullamore (Offaly) and a brewery at Drogheda (Louth).

Though the lack of industry was deplored in the late 19th century, there were some products of considerable distinction, such as the poplins from Dublin made of silk and wool, the handmade lace from Limerick, and Waterford glass. Fine suitings were made in County Cork and there was a continuing tradition of skilled craftsmanship in furniture, silver and footwear in the cities. The problem was that these products were expensive, and the cheaper, mass-produced goods were not made to any significant extent, and certainly not at competitive prices. From 1932, as noted above, tariffs gave some protection to home industries, of which of great variety were established throughout the country, and on this basis there are hopes of an expansion of the export trade in industrial products. For this Ireland has three advantages: an adequate labour supply, cheap power and land for factory sites, even if raw materials may not be available.

Capital has traditionally been exported from Ireland by investments in British and other overseas securities, but government policy is to encourage investment at home and also to attract foreign capital. In the earlier years of modern industrialization over half the capital for any incoming firm had to be found in Ireland, but new concerns are now offered substantial grants, liberal credit facilities and tax concessions, and the government is willing to take up equity interests in firms that require capital for expansion and development. Of overseas firms, the first major group to be established included many famous British and continental concerns supplying the Irish market, and the second included more than 100 factories founded since the mid-1950s partly to supply export markets. In the second group are several firms of the Federal Republic of Germany, but at Shannon airport, described as "the world's first free port of the air age," there are also Japanese, Southern Rhodesian, South African and Dutch firms, and the products include fabrics, transistor radios, pianos, electronic control mechanism, plastic buttons, wire mesh and precision fasteners for the aircraft and other industries. Some 1,500 men are employed in this "free port." At Killarney a German cranemaking factory has been remarkably successful and has given much-needed permanent employment in the town and district. Steadily, government planning, mainly through the efforts of the Industrial Development authority, has fostered industrial expansion to reduce the rate of emigration (still high) and improve economic conditions throughout the country.

The long-established and the newer industries together fall into five main categories, the first three of which are closely linked with agriculture while the last two could rank as consumer industries. These five groups are: the production of processed agricultural goods, such as butter, bacon, tinned meat and sugar; the manufacture of drinks, which includes distilling, brewing and malting; industries serving the farmers, such as milling and the making of machinery, farm tools and fertilizers; the manufacture of leather and clothing; and the production of miscellaneous consumer goods. It is in the last two categories that the advance has been most marked since 1932, and official statistics show that the total number directly engaged has more than doubled since that date. In 1931 there were 65,000 persons so engaged, but by the early 1960s the number had risen to more than 150,000, excluding the large number serving industry in various clerical, mercantile and other ways. One aim has not been achieved—the provision of new employment on a sufficient scale to offset emigration.

The first group, agricultural staples, includes creameries; bacon factories, in the main cities and in a number of provincial towns, some of which date back for more than a century; and the canned meat plants in Dublin, Waterford and Roscrea. Sugar beet production has already been mentioned. A curious postwar addition has been the manufacture of chocolate crumb, which is made from milk, sugar and cocoa. A laboratory for research work on food processing was opened in Carlow in 1962.

The second group includes whiskey (so spelled to distinguish it from Scotch whisky) and stout, both of which are significant exports; beer; cider; and mineral waters (soft drinks). The last-named have a large sale in Ireland for, contrary to general belief, a substantial proportion of the population never consume alcoholic drinks.

Industries serving the farmers are varied. The largest mills are in the major ports—Dublin, Cork, Limerick and Waterford—though there are others of considerable size in Galway city, in Sligo and in Donegal. Agricultural machinery is made at various centres and includes some old concerns such as that at Wexford, but though the output has increased considerably, hardly one-third of the demand is met from home manufacture. Tractors have become prevalent since World War II and are produced at the motor works in Cork. Firms making fertilizers have increased their production and depend on imported raw materials; the main centres are at Dublin, Drogheda, Wicklow and Cork.

Leather and clothing industries have been greatly expanded. They include woolen and worsted factories that date back to the 18th century, a few linen mills that are outposts from the industry of Northern Ireland (for example, in Drogheda and in Ravensdale near Dundalk), some new cotton mills, a sewing-cotton works at Westport, and a number of shirt factories in the east of County

Donegal, most of them allied to firms in Londonderry. The clothing industry, including hosiery and knitwear, employed about 30,000 workers in the early 1960s, more than twice the figure in 1930, and little clothing is now imported except for luxury goods; some materials and clothing are exported, notably Irish tweeds and hand-knitted sweaters. In the footwear industry there has been a similar growth, and old-established tanneries, such as those at Limerick, Tralee and Cork, have been supplemented by newer ones in various provincial towns. Many of the firms in such industries bear honoured names in Britain and a few are linked with continental European countries.

The last group consists of miscellaneous consumer goods, which have expanded considerably since 1930. This group includes the making of bread, confectionery, tobacco and paper; printing; furniture manufacture; and a widening range of metal and engineering trades. The first steelworks in the republic was established on Haulbowline Island, formerly a British naval base in Cork harbour, in 1938. At Cork there are the Ford motor works which began production in 1919, a rubber factory and a number of engineering works. A large oil refinery has been built at Whitegate beside Cork harbour. Since 1930 many light industries have been placed in various country towns: for example, razor blades are made at Carlow and Enniscorthy, enamelware at Tralee (as well as at Dublin), aluminum utensils at Nenagh, cutlery and ropes at Newbridge (Kildare), electric cables at New Ross, electric bulbs at Bray and water pipes at Balbriggan (Dublin).

The industrial developments in the republic since the 1930s are an interesting example of national planning with a social as well as economic purpose. Government assistance has been given on a scale that is generous in relation to the national resources. Not all the industries have been successful, nor has the industrial program solved the emigration problem. But much-needed employment has been given at a time when the numbers working on the land were diminishing, partly through the continued union of small farms into larger ones and partly through the replacement of workers by machinery. Without the electrification scheme, the industrial program could not have achieved even its existing measure of success.

6. Power.—When the Irish Free State government began its electrification scheme on the Shannon in the 1920s the fear was that the number of customers would be inadequate; but soon after the project was completed in 1929 the search began for other suitable rivers. In the early 1930s the demand was sharply increased by the industrial program, and by the early 1960s the number of units sold exceeded 2,400,000,000, most of which was for general domestic supply, industrial motive power and machinery on the farms; very little was used for traction as there are no electric railways or trams (streetcars). Although the consumption per head is less than in many other countries, several power stations have been built: on the Liffey at Pollaphuca and Leixlip, on the Lee at Inniscarra, on the Erne at Cliff and Cathaleen's falls and on the Clady in County Donegal. These hydroelectric stations provide 40% of the supply, and a further 29% comes from peat-fired stations, of which there are three on midland bogs at Allenwood, Portarlington and Ferbane, and several along the west coast from Donegal to Kerry. The remaining 31% of the power is supplied from plants using imported coal and oil at Dublin and Cork. The plant at Arigna uses local coal.

7. Transport and Communications.—After World War II the railways of Ireland were no longer profitable. The Dublin government in 1944 set up a state company, *Coras Iompair Eireann*, to run the Great Southern railway and the Dublin United Transport company, as well as lorry (truck) services throughout the country; in 1950 the Grand Canal company was added to C.I.E. By 1953 the Great Northern railway was facing immediate bankruptcy and was taken over jointly by the governments of the Republic of Ireland and of Northern Ireland. Under the Great Northern Railway act of 1958 the section of this railway which lay within the Republic was taken over by C.I.E. and the remainder transferred to the Ulster Transport authority. Also in 1958 the Transport act authorized the elimination of uneconomic transportation and many branch railway lines have been closed. There is, for example, no railway line west of Killarney, and all the railway lines west of Cork are in disuse; eventually there will be railway communications only between the main towns of the country, with stations at intervals of ten to twenty miles.

From 1944 the aim has been to integrate all transport services by train, bus and truck. Bus services normally connect with trains and use the station yards as parking grounds. Truck services run by C.I.E. penetrate roads of surprising remoteness. The tourist trade is encouraged by special services which include coach tours at charges including hotel costs and all meals, and one-day tours of Killarney and Connemara from Dublin, designed especially for people making only a short stay but wishing to have a glimpse of the west of Ireland. Another tourist development is a trip by boat along the Shannon by C.I.E. The number of private cars has steadily increased but in the early 1960s was only 1 for 16 of the population, though many farmers have vans.

Except in Dublin and its vicinity the roads of Ireland carry very little traffic: substantial improvements have been made by widening and straightening out difficult sections.

The air services with the heaviest traffic are from Dublin to London, Manchester, Glasgow, Liverpool and Birmingham; and, of the continental flights, to Paris and Lourdes (for pilgrims). Shannon airport has transatlantic connections (*Aer Linte*) and has added an industrial estate whereby participating companies are exempt from all tax on exports operations until 1983 and pay only nominal rates; profits can be freely repatriated. An airport was opened in Cork in Oct. 1961 for domestic services. Some cargo is taken by air, but it represents less than one-tenth of the overseas trade.

Telecommunications.—There are Atlantic cable stations at Knightstown on Valentia Island, and at Waterville in County Kerry. Several of the island communities off the west coast now have radio telephonic communication with the mainland. The ministry of posts and telegraphs also controls radio and television broadcasting. Radio Eireann permits limited advertising. Telefís Eireann, the republic's television service, was inaugurated New Year's Eve 1961.

8. Shipping and Ports.—Of the cargo trade, more than half is handled by Dublin, which has extensive quays on the river Liffey and a large basin with warehouses and a grain silo. Dublin handles about two-thirds of the imports and half the exports. Cork, with Cobh, the chief Irish port of call for transatlantic liners, has about one-eighth of the overseas trade; Waterford and Limerick have mainly coastal shipping. Other ports, such as Drogheda, Dundalk and Rosslare on the east, and Foynes and Galway on the west, are little used. The Irish merchant marine service is small but growing. The passenger services are from Liverpool to Dublin, Holyhead to Dun Laoghaire (Kingstown), and Fishguard to Rosslare and Cork.

9. Overseas Trade.—The adverse balance of trade, usually large in the 1950s (except in 1957 when there was a favourable balance with a surplus of £9,000,000), declined in the early 1960s. The value of exports and re-exports rose from about £151,000,000 in 1959 to more than £180,000,000, and although the value of imports was greater by about £30,000,000, the balance was met by invisible earnings, which included the returns from investments abroad (mainly in Great Britain), remittances from emigrants, pensions paid to senior residents from abroad such as former members of the British armed forces and repatriated Irish-Americans, and—increasingly significant—the profits of tourism.

In some years there have been efforts to restrict the imports of consumer goods, apart from those in normal tariff legislation, but normally at least half the imports are classified as "materials for further production." Of the exports more than half are agricultural, including live cattle, chilled beef and mutton, and horses. Other agricultural exports include raw wool, bacon, canned meat and—since World War II—chocolate crumb. The butter export is now slight and the sale for poultry and eggs has declined sharply. Many exports fluctuate from year to year but hopeful signs in the early 1960s were the increased sale of textiles and the opening-up of markets for various other consumer goods. The exports of beer and liquor, chiefly stout and whisky, remain fairly stable. Irish

farmers would undoubtedly welcome an expansion of exports of agricultural origin, especially of butter, bacon and canned goods, but in all these the British market is well supplied from continental and commonwealth sources. (T. W. Fr.)

10. Finance.—The gross national product (GNP) was £399,000,000 in 1950 and £649,000,000 in 1960. The increase in gross national product in real terms between 1950 and 1960 was about 18%, representing an average annual increase of about 1½%. Since there was some reduction in both total population and in the labour force during this period, real output per head rose by about 24% or approximately 2% per annum. Between 1950 and 1960 the proportion of national income arising in agriculture (including forestry and fishing) fell from 28% to 24%. The proportion generated in the industrial sector rose from 25.7% to 28.2% during the same period.

The average annual growth rate in GNP masks wide variations. There was a steady rise in real gross national product from 1950 until 1955, when a very large balance of payments deficit, necessitating corrective measures, occurred. Thereafter, real GNP fell, being more than 4% lower in 1958 than in 1955. The government's program for economic expansion was published in 1958. It was designed to increase national output, improve the competitiveness of Irish products in export markets and generate a dynamic of progress within the economy. This five-year program contributed to the improvement in the economic situation: in 1959 real national income rose by 4½%, and in 1960 by 5%, and this growth was maintained in the early 1960s. This improvement was achieved without any significant rise in internal costs and prices and without pressure on the balance of payments. It was associated with a substantial growth in exports, especially of manufactured goods.

Taxes are both direct and indirect. Direct taxation is levied upon income and profits, estates and motor vehicles, and also as stamp duties. Indirect taxes are customs and excise duties, and minor taxes. Local taxes, in the form of rates, are levied as in Great Britain by local authorities. In the early 1960s government revenue and expenditure were well in excess of £160,000,000 with a current deficit of more than £4,000,000 and a total capital expenditure of about £50,000,000. The capital liabilities were £176,300,000 in March 1951 against which were held assets valued at £95,700,000. By the early 1960s both liabilities and assets had about tripled. In 1950–51 the debt charged was £7,200,000 of which £5,300,000 was charged to taxation; the corresponding figures in the early 1960s showed a fivefold increase.

Banking and Currency.—The republic has its own currency. The monetary unit is the Irish pound, with the same value as the pound sterling. The principal circulating medium is the legal tender note convertible into British legal tender at the Bank of England.

The Central Bank of Ireland, established by the Central Bank act (1942) regulates currency and banking policies in consultation with the ministry of finance. Under the bank act, eight associated banks operate in the republic.

IRENAEUS, SAINT (*c.* 130–*c.* 200), a father, doctor and saint of the ancient church. Little is known about his life. His letter to Florinus, preserved in Eusebius' *Ecclesiastical History* (V, xx, 4–7), shows that he remembered the aged Polycarp, disciple of the apostle John. Irenaeus was therefore presumably born *c.* 130 in Asia Minor. He later went to southern Gaul as a missionary. In 177–178, now a priest, he was entrusted with a mission to Eleutherius, bishop of Rome, taking with him, according to Eusebius, a letter from the martyr church of Gaul interceding for the peace of the church, then disturbed by the Montanist controversy (*see* Montanism). On his return Irenaeus was consecrated bishop of Lugdunum (modern Lyons), in succession to Pothinus, who had been martyred in the great persecution at Lugdunum. About 190 he wrote a letter to Victor, bishop of Rome, protesting against the attempt of the latter by threat of excommunication to constrain the church of Asia Minor to abandon its traditional but peculiar date for Easter. Though Irenaeus supported the Roman usage, his letter is a strong plea for toleration. He apparently continued at Lugdunum till his death, *c.* 200. There is no secure foundation for the tradition that he was martyred. His feast day is June 28.

Works.—Eusebius (*Eccl. Hist.* V, xx, 1–4; xxvi) mentions a number of letters and works written by Irenaeus to defend the doctrine and unity of the church. Apart from the citations preserved in Eusebius all but two of these have perished. (1) Of his major work, *Adversus Haereses* ("Against Heresies"), written against Gnosticism, portions exist in the original Greek and the whole in an old Latin translation. (2) His *Demonstration of the Apostolic Preaching,* a handbook of Christian evidences long considered lost, was discovered in Armenian translation in 1904 at Erivan (now Yerevan), in Armenia.

Historical Interest.—During the 2nd century the amalgamation of elements of the secular thought of the time with the primitive Christian teaching increasingly produced heretical doctrine and the rise of schismatic bodies. The reaction of the church to this was a heightened consciousness of its own doctrinal and ecclesiastical authority, and an attempt to define more clearly its heritage of Scripture, doctrine, ministry and sacraments. Irenaeus is the leading surviving witness to this process during a very formative period.

Scripture.—Irenaeus shows the development of the authoritative canon of the New Testament, to the exclusion of other books. He quotes all the books except Hebrews, III John and Jude, and is the first writer to state that there are, and can only be, four Gospels, giving their traditional authorship (*Adv. Haer.* III, i, 1; xi, 8). He uses the apostolic writings as an authority in a manner almost indistinguishable from the original Old Testament Scriptures.

Creed.—Irenaeus frequently mentions the "Rule of Truth," and rehearses the main articles of belief in a manner reminiscent of the Apostles' Creed (*e.g., Adv. Haer.* I, x, 1); this indicates the development of a baptismal creed, for the exclusion of heresy.

Ministry.—The generally allowed allegorical interpretation of Scripture, which derived secondary "hidden meanings" from the text, enhanced the ever-present difficulty in establishing an accepted authoritative exposition. Heretics employed the same method to substantiate their positions. Irenaeus advanced the claim that the consensus of all the bishops of the churches of admitted and continuous apostolic foundation provided the sole safe guide to the interpretation of Scripture (*e.g., Adv. Haer.* IV, xxvi, 5; xxxii, 1). This disallowed the Gnostic claim of a succession of teachers possessing a secret tradition. Thus the primary interest of Irenaeus in the ministry is as a teaching medium, though he acknowledges the sacramental aspect.

The Roman Church.—Irenaeus points to the Roman Church, founded by the two chief apostles, as the eminent though not exclusive example of this principle of episcopal teaching authority (*Adv. Haer.* III, iii, 2). To Roman Catholic historians this is an important stage in the explication of the principle of papal primacy, to others an early but significant stage in the evolution of the papacy.

Theological Interest.—Irenaeus can employ elements of Greek thought, and thus expounds Christ as the Logos. His constructive thought, however, chiefly consists in the restatement and interpretation of biblical attitudes, in opposition to Gnostic mingling of Hellenic and eastern with Christian elements. In general, he both recalls Christian thought to its biblical origins and prefigures much later Catholic orthodoxy.

God and Creation.—Gnosticism taught that God is a remote Su-

preme Being; the material creation is essentially alien to him and has contact with him only through a long chain of subordinate "emanations." To Irenaeus God is the present, creative, active and personal God of the Old Testament (*e.g., Adv. Haer.* II, xxx, 9).

The Trinity.—The doctrine of the "Two Hands of God," the divine Son and Spirit, represents the immediate activity of God in the world, in creation, revelation and redemption (*e.g.,* IV, xix, 2).

The Atonement.—The incarnate divine Son undid the effect of Adam's disobedience by living as man a life of sinless obedience, culminating in his death (*e.g.,* III, xxiii, 1; V, xxi, 1). This victorious "going over the ground again" in reverse direction by the "second Adam" Irenaeus calls recapitulation.

Salvation.—Irenaeus can expound this as the restoration to mankind of "divinity," by virtue of the union of the human and divine in Christ (III, xix, 1). He also has a firm grasp of the New Testament principle that salvation is a moral change, appropriated by personal loving trust in Christ the Victor (I, xxv, 5; IV, xiii, 4).

Christian Hope—Irenaeus has a vivid expectation of Christ's visible Second Advent (III, xvi, 8) and of the earthly millennial Kingdom (V, xxxiii, 3–4).

Bibliography.—The best edition of the *Adversus Haereses* is that by W. W. Harvey (1857); Eng. trans. in the "Ante-Nicene Christian Library" (1868–69). Eng. trans. of the *Demonstration* are those of J. A. Robinson (1920) and J. P. Smith (1952); French trans. by L. Froidevaux (1959). *See* also "Saint Irénée," in *Dictionnaire de théologie catholique* (1923); P. Beuzart, *Essai sur la théologie d'Irénée* (1908); G. N. IRENE, the name of several Byzantine empresses.

Irene (*c.* 752–803), the wife of Leo IV, was originally a poor but beautiful Athenian. On Leo's death in 780 she became guardian of their ten-year-old son, Constantine VI, and co-emperor with him, though virtually holding supreme control for ten years. Her most notable act was the restoration of the use of icons in the Orthodox Church, a policy which she had always favoured, though compelled to conceal this during her husband's lifetime (*see* Iconoclastic Controversy). She had Tarasius, one of her supporters, elected patriarch of Constantinople (784) and then summoned a general church council. This met in 786 at Constantinople to restore the use of icons, but it was broken up by the iconoclast soldiers. Another council was then convened at Nicaea in 787, and the cult of images was restored. This was recognized as the seventh ecumenical council, and the Eastern Church was once more in communion with Rome (*see* Council).

As Constantine approached maturity he resented her autocratic sway and that of her favourite, the logothete Stauracius. An attempt to free himself by force was crushed by the empress, who demanded that the military oath of fidelity should thenceforward recognize her as senior ruler. Discontent at this moved the Asian troops of the Armeniakon theme to open resistance in 790 and they formally proclaimed Constantine VI as sole ruler. Irene was banished from court, but in 792 was allowed to return and her title of empress was confirmed. The rival factions, however, remained. Irene, by skilful intrigues with the bishops and courtiers, organized a powerful conspiracy against Constantine, who was arrested and blinded at his mother's order (797).

Irene then reigned alone as "emperor" (not empress) for five years. In 798 she reopened diplomatic relations with Charlemagne, and in 802 there was some question of a marriage between herself and Charlemagne; but according to Theophanes, who alone mentions it, the scheme was frustrated by Aetius, one of her favourites. An alliance between Constantine and Charlemagne's daughter, Rothrude, had already been proposed in 781, but this had been broken off by Irene. In 802 the higher officials and generals conspired against her and placed on the throne Nicephorus, the minister of finance (logothete). The haughty and unscrupulous empress was exiled to Lesbos, where she died in 803. Her zeal in restoring icons and her patronage of monasteries has given her a place among the saints of the Greek church. Her feast day is Aug. 9.

Irene (Irene Ducas) (*c.* 1066?–1120), the wife of Alexius I, is well known from the description of her in the *Alexiad* of their daughter Anna Comnena. She failed to persuade Alexius to divert the succession from their son John to Nicephorus Bryennius, Anna's husband, and when her *coup d'état* was forestalled by John she retired to the monastery which she founded in Constantinople.

Irene (d. 1161), the first wife of Manuel I Comnenus, was the daughter of the count of Sulzbach and sister-in-law of the German king Conrad III, who arranged her betrothal. The marriage was celebrated at Constantinople in 1146. The new empress, who had changed her earlier name, Bertha, for one more familiar to the Greeks, became a devoted wife; contemporaries remarked on the simplicity of her manner and appearance in contrast to the more sophisticated Byzantine ladies of that age.

IRENG RIVER (also known as the Maú River), rises in the Guiana highlands and flows south for about 124 mi. to join the Tacutú river, a tributary of the Rio Branco, in northern Brazil. From its source to its junction with the Tacutú, the Ireng forms the boundary between Brazil and British Guiana. It rises in an area of heavy forest, but emerges farther downstream to flow through a part of the Rupununi savanna. Diamonds have been found in the gravels along its valley. (P. E. J.)

IRETON, HENRY (1611–1651), English statesman and soldier, the son-in-law and close friend of Oliver Cromwell, was born at Attenborough, Nottinghamshire, in the autumn of 1611. Educated probably at Nottingham grammar school and at Trinity college, Oxford, and the Middle Temple, he was said by Anthony à Wood to have been "a stubborn and saucy fellow." When the Civil War came he raised a troop of horse which appeared in the thick of the fighting at the battle of Edgehill, but was afterward sent back to protect the county of Nottinghamshire where it had been raised. In 1643 Ireton became a major in a cavalry regiment which joined Oliver Cromwell at Grantham and fought in a small action at Gainsborough in Lincolnshire. Ireton became friendly with Cromwell who appointed him deputy governor of the Isle of Ely and an officer in his own cavalry regiment. In the summer of 1646 Ireton married Cromwell's eldest daughter, Bridget, by whom he had a son and three daughters. Meanwhile he served in the battle of Marston Moor in 1644, and later backed Cromwell in his quarrel with his commander, the earl of Manchester. In 1645 he was given his own regiment in the New Model army. At the battle of Naseby he was put in command of the left wing but was driven from the field by Prince Rupert. Later in 1645 he was at the siege of Bristol and was elected member of parliament for Appleby in Westmorland.

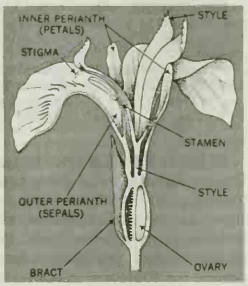
During 1647 Ireton emerged as a political leader with a mind of his own. He tried to act as mediator between the army and the house of commons and worked hard to negotiate a general settlement between Charles I, the parliament and the army. For this purpose he drew up a constitutional scheme known as the "Heads of the Proposals" which was submitted for discussion at a meeting of the council of the army held in the autumn of 1647. Ireton was both a firm believer in the claim of the army to be recognized as a political force and a strong opponent of the more democratic theories of the Levellers and the so-called "agitators" or agents of the common soldiers in the New Model army. In his view manhood suffrage would undermine the institution of private property, while he insisted that the engagements made by the army leaders must be kept. After the second phase of the Civil War Ireton turned against the king and was in favour of his being brought to trial; he was one of the signatories of Charles's death warrant. In 1649 Ireton was promoted major general and served under Cromwell in Ireland. When Cromwell left Ireland he stayed behind as

lord deputy and acting commander in chief. He died of fever after taking part in the siege of Limerick on Nov. 28, 1651, and was buried with some pomp in Westminster abbey.

Henry Ireton, though not a great soldier, was an able, devoted and selfless administrator. He was also the most profound political thinker on the Puritan side. It was said that "Cromwell only shot the bolts that were hammered in Ireton's forge," and Cromwell certainly suffered a public as well as a personal loss by his son-in-law's early death.

See R. W. Ramsey, *Henry Ireton* (1949). For Ireton's political speeches and ideas, *see* A. S. P. Woodhouse (ed.), *Puritanism and Liberty* (1938). (M. P. A.)

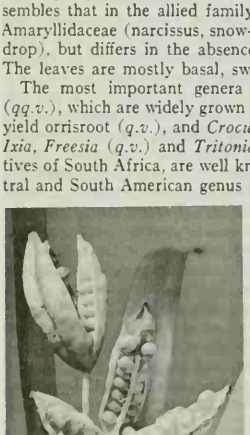
IRIDACEAE, the iris family of flowering plants, belongs to the order Liliales (or Liliiflorae) of the group of monocotyledons. It contains more than 1,000 species in about 60 or more genera, widely distributed in temperate and tropical regions and especially centred in Central America and subtropical Africa. The members of this family are generally perennial herbs growing from a corm, as crocus and gladiolus, or a rhizome, as iris; more rarely, as the Spanish iris, from a bulb. A few South African representatives have a shrubby habit. The flowers are hermaphrodite and are regular, as in iris and crocus, or with a symmetry in the median plane, as in gladiolus. The arrangement of flower parts is in groups of three and resembles that in the allied family Amaryllidaceae (narcissus, snowdrop), but differs in the absence of the inner whorl of stamens. The leaves are mostly basal, sword-shaped and overlapping.



FROM GROOM, "ELEMENTARY BOTANY," (G. BELL)

LONGITUDINAL SECTION THROUGH FLOWER OF IRIS PSEUDACORUS

The most important genera are *Crocus, Iris* and *Gladiolus* (*qq.v.*), which are widely grown as ornamentals; some *Iris* species yield orrisroot (*q.v.*), and *Crocus sativus* produces saffron (*q.v.*). *Ixia, Freesia* (*q.v.*) and *Tritonia* (including *Montbretia*), all natives of South Africa, are well known in cultivation, as is the Central and South American genus *Tigridia* (*see* TIGERFLOWER). In North America there are many native species of *Iris* and *Sisyrinchium*, especially in the east, and a few species of *Alophia, Calydorea* and *Eustylis* (a monotypic genus). *Sisyrinchium*, blue-eyed grass, is a new world genus extending from arctic America to Patagonia and the Falkland Islands; *S. angustifolium*, an arctic and temperate North American species, is also native in Galway and Kerry in Ireland. Other native British representatives of the family are: *Iris pseudacorus* and *I. foetidissima; Gladiolus illyricus*, a rare English plant; and *Romulea columnae.*



JOHN MARKHAM

SEED PODS OF IRIS FOETIDISSIMA

IRIDIUM, a chemical element, is a precious heavy white metal, one of the six platinum metals (*q.v.*). Its specific gravity, 22.56, is equaled by osmium; these metals are the densest terrestrial substances. With a melting point of 2,450° C., iridium is difficult to fuse. Its boiling point is estimated at above 4,800° C. The metal is hard and brittle; however, it becomes ductile and can be worked at a white heat, from 1,200° C. to 1,500° C. The chemical symbol of iridium is Ir, atomic number is 77 and atomic weight is 192.2.

In the massive state the metal is practically insoluble in acids and is not even attacked by aqua regia, which dissolves gold and platinum. Iridium is oxidized by a mixture of fused potassium hydroxide and potassium nitrate. Iridium crucibles are superior to those of platinum because of their resistance to carbon and phosphorus at high temperatures. However, their gradual loss in weight by air oxidation above 1,000° C. is greater than that of platinum.

Because of difficulties in preparation and fabrication, the pure metal has no important applications. The element's principal use is in the preparation of platinum alloys. Pure platinum is a soft metal and unsatisfactory for many uses. Alloyed with from 5% to 10% iridium, it forms a readily worked metal, much harder and stiffer and more resistant to chemical attack.

For ordinary purposes these iridium-platinum alloys are always used unless pure platinum is needed for special reasons. They are used for jewelry and surgical pins and pivots. With their superior resistance to the action of the high-temperature electric spark they are widely used for electrical contacts and sparking points.

The international prototype standard metre of length and kilogram of mass have been constructed from the alloy containing 90 parts platinum and 10 parts iridium.

Iridium has also been used as a major component of precious metal tips on gold fountain pens.

Iridium is generally obtained from the native alloy, osmiridium, but is always found in small amounts in platinum-bearing ores. Its discovery in the acid-insoluble residues of platinum ores was announced by Smithson Tennant in England in 1804. It was named by him in consequence of the various colours of its compounds. In metal preparation, osmiridium is heated with zinc to give an acid-soluble alloy. After separation of osmium as OsO_4 the platinum is removed by repeated fractional precipitations of the compound $(NH_4)_2PtCl_6$. The ammonium hexachloroiridate, $(NH_4)_2IrCl_6$, then crystallized, is decomposed to give sponge metal.

Iridium forms the oxides Ir_2O_3 and IrO_2 and important series of compounds with oxidation states +3 and +4. In many of these compounds it exists in complexes in which chloride, ammonia, water and other groups are bonded covalently to a central iridium atom. These complexes are of the inert type in that the groups are replaced slowly.

Iridium compounds decompose readily upon ignition, and the element in analysis is determined gravimetrically as metal. Strong oxidizing agents or electrolysis will give oxidation states higher than +4 of transient stability in water.

(D. S. MK.)

IRIGOYEN, HIPÓLITO (1850–1933), Argentine statesman and first president elected by broad popular suffrage, was driven from office during his second term in Argentina's first successful 20th-century revolution.

Born in Buenos Aires, Irigoyen became a lawyer, teacher, rancher and politician, and in 1896 he took control of the Radical party. His relentless effort to obtain free elections succeeded in winning from the conservative oligarchy the Sáenz Peña law (1912). Under this provision for the secret ballot, Irigoyen was elected president. During his term (1916–22) he and his Radical party followers in congress maintained Argentina's neutrality in World War I. Measures that regulated labour conditions were also passed, but these were not strongly enforced, and in 1919 a serious strike, in part politically inspired, was violently broken by the government.

Re-elected overwhelmingly in 1928, despite the opposition of his former close associate, Marcelo T. de Alvear, who had served as president from 1922 to 1928, the increasingly senile Irigoyen lost his grip on affairs. Corruption and stagnation within his administration cost him much support, which went over to the opposition formed by his long-time conservative enemies. The business depression that began in 1929 further weakened his position, and a relatively bloodless conservative-military coup in 1930 ended his career. He died in Buenos Aires.

Austere in much of his personal life, obscure in many of his public declarations, yet immensely popular almost to the end of his career, Irigoyen failed to implement in Argentina the democratic

reforms that he had tenaciously advocated before reaching power. (T. F. McG.)

IRINGA REGION, TANGANYIKA (TANZANIA), established in October 1963, comprises Iringa and Njombe districts and is bounded north by Singida and Dodoma regions, north and east by Morogoro Region, southeast by Ruvuma Region, southwest by Malawi, and west by Mbeya Region. Area 21,750 sq.mi. (56,333 sq.km.). Pop. (1957) 489,291. In Njombe District are the Uwemba Mountains (7,400 ft. [2,260 m.]), the Kipengere Range (9,715 ft. [2,961 m.]), and the Livingstone Mountains (9,600 ft. [2,930 m.]) whose precipitous slopes flank the eastern shore of Lake Nyasa in the Great Rift Valley. The eastern boundary of Iringa District follows the escarpment of the central plateau of Tanganyika (Archean granites) overlooking the Kilombero Valley. The Great Ruaha River crosses the district and forms the northeastern boundary. Coal reserves are found in Karroo deposits in the valley of the Ruhuhu River flowing to Lake Malawi along the boundary of Ruvuma Region. Rainfall, mainly during December–April, is more than 60 in. (1,500 mm.) on high ground where mists and frost (over 5,000 ft. [1,500 m.]) are common. The plateau, however, is hot and relatively dry. Regional headquarters are at Iringa. The largest tribe are the Hehe; there are small numbers of European settlers. Tea, coffee, and tobacco are grown in Iringa District; pyrethrum, wheat, and wattle (for tannin extract) in Njombe District. (J. M. KE.)

IRIS, a large genus of popular herbs of the family Iridaceae much grown for ornament. They have a petaloid six-parted perianth, an inferior ovary and only three stamens (the outer series), being thus distinguished from the Amaryllidaceae, which have six stamens. They are handsome showy-flowered plants, the Greek name *Iris* ("rainbow") having been applied on account of the hues of the flowers. The genus contains more than 150 species, widely distributed throughout the north temperate zone.

In North America there are about 30 native species, found chiefly in the eastern United States; among the best known are the lilac-to purplish-coloured blue flag (*I. versicolor*), which grows in wet places from Newfoundland to Manitoba and southward to Florida and Arkansas, and the western blue flag (*I. missouriensis*), native to wet soils from North Dakota and New Mexico westward to California and British Columbia.

The Eurasian *I. pseudacorus*, the yellow flag or iris, is common in Britain on riverbanks and in marshes and ditches. It was called the "water-flag" or "bastard floure-de-luce" by John Gerard in his *Herball* (1597); its flowers appear in June and July and are of a bright golden yellow colour. *I. foetidissima*, the stinking iris, gladdon or gladwin or roast-beef plant, is a native of England south of Durham and also of Ireland, southern Europe and north Africa. Its foliage, when bruised, has an offensive odour.

JOHN MARKHAM

YELLOW FLAG IRIS (IRIS PSEUDACORUS)

Iris florentina, with white or pale blue flowers, a native of the south of Europe, is the chief source of the violet-scented orris-root (*q.v.*) used in perfumery. *Iris pallida* and its relatives appear to be the origin of the large common blue iris of gardens, the bearded iris or fleur-de-lis and probably the Illyrian iris of the ancients. *I. pallida* and *I. variegata* have also been assumed to be the parents of the so-called German iris, better known as tall bearded iris; but these plants, long known as *Iris germanica*, are of very doubtful origin, never having been found as native plants.

The garden plants known as Spanish iris (*I. xiphium*) and English iris (*I. xiphioides*) are both of Spanish origin and have very showy flowers. The so-called Dutch irises are derived from *I. xiphium*. Along with some other species, such as the netted iris (*I. reticulata*) and the Persian iris (*I. persica*), both of which are fragrant, they are great favourites with florists. All these just mentioned differ from those formerly named in the nature of the underground stem, which forms a bulb and not a strict creeping rhizome as in *I. pseudacorus*, *pallida*, *florentina*, etc.

For many centuries, probably long antedating the culture of any of the above species, Japanese horticulturists were hybridizing what are today known as Japanese iris. Hundreds of named forms of these, in a variety of colours, are perhaps the showiest of all garden irises. They appear to be derived from *I. kaempferi* or its allies, a plant with a creeping rootstock, long leaves and, in the cultivated forms, very large flowers (six inches across in some varieties). The original species, which is wild in eastern Asia, was in ancient times developed by Japanese families or guilds, some of whom produced identical varieties but applied their own names to them. The hundreds of named forms are hence in much confusion, but the following appear to be reasonably accurate: Gold Bound and Morning Mists (white); Blue Belle and Blue Bird (blue), Pink Progress (pink) and Mahogany and Purple and Gold (reddish purple).

J. HORACE MCFARLAND COMPANY

HORTICULTURAL FORM OF TALL BEARDED IRIS

The iris flower is of interest because of the flower shape, which appears to prevent self-pollination and ensure cross-pollination by insect visitors. The flower parts are so ingeniously arranged that an insect bearing pollen from one flower will, in entering a second, deposit the pollen on the stigma; the pollen which it bears in emerging will not be rubbed off on the stigma of the same flower.

The rootstocks of irises may be planted shallowly in spring (in colder climates) or autumn in an open, sunny exposure and well-drained garden soil. Propagation is commonly by division of rootstocks just after the flowering period. Irises do not breed true from seed; however, seeds may be planted upon ripening and may germinate the following spring. Although irises thrive under a variety of conditions, mulching is desirable in cold climates.

There are large collections of iris at Washington, D.C., and at Cornell university, Ithaca, N.Y. The American Iris society has published a catalogue comprising thousands of varietal names, and the Royal Horticultural society has issued a schematic key for the whole genus, as well as a key for the tall bearded sorts. The keys are tables by which the plants can be identified on the basis of their relationships.

See N. L. Cave, *Iris*, rev. ed. (1959); Wilma L. Vallette, *Iris Culture and Hybridizing for Everyone* (1961). (N. TR.; X.)

IRISH LANGUAGE: *see* CELTIC LANGUAGES.

IRISH LITERATURE. Ireland is unusual in that it has two literatures, one in the native language and another in the language of the English conquerors. This excludes numerous writings in Latin, mostly theological and antiquarian (for which *see* LATIN LITERATURE: *Medieval and Renaissance Literature*), as well as some works in French, *e.g.*, the early poems of the Norman conquerors (*see* ANGLO-NORMAN LITERATURE). This article deals first with Gaelic literature and then with Irish writing in English, commonly called Anglo-Irish literature, and is divided into the following main sections:

I. Gaelic Literature
  A. Early Period
    1. Verse
    2. Prose
  B. Middle Period
    1. Bardic Verse
    2. The Fenian Cycle
    3. Other Prose
  C. Late Period

1. Verse
2. Prose
D. The Gaelic Revival
II. Anglo-Irish Literature
1. The Beginnings
2. The 18th Century
3. The 19th Century
4. The Literary Renaissance
5. The Moderns

I. GAELIC LITERATURE

The Celtic language spoken in Ireland from the earliest historic period, often described as Gaelic (or Goidelic, from Old Irish *Goidel*, a Brythonic loan word of which the modern equivalent is Welsh *Gwyddel*, "Irishman"), has no close connections on the continent of Europe, where evidence shows instead a connection with that form of Celtic of which the surviving Brythonic languages are representatives (*see* CELTIC LANGUAGES). Nor is it certain when Goidelic was brought to Ireland, but research suggests a date not long before the beginning of the Christian era.

The earliest evidence consists of sepulchral inscriptions in the Ogham alphabet (*see* OGHAM WRITING). These are found mainly in the southwest of Ireland, but there are examples from the rest of the country and from Wales, where small Goidelic colonies existed. These inscriptions, usually ascribed to the 4th and 5th centuries, show an archaic state of the language, phonologically very close to the early Brythonic of British and Gaulish inscriptions; its relation to the Irish found in the earliest literary sources may be compared with that between Latin and Old French. The alphabet in which these sources were written was the Roman one, introduced by the Christian missionaries in the 5th century. The precise date at which it began to be used for writing Irish is uncertain, for there are no extant examples before the 8th century, and even then only incidentally, in scribal notes and glosses. The language of the 8th- and 9th-century manuscripts, conventionally called Old Irish, provides an indispensable criterion for dating other material; the discovery in later manuscripts of linguistic forms considerably more archaic than those of the classical Old Irish period indicates that the compositions in which they occur belong to the 7th century or perhaps even the 6th. None of these later manuscripts, on which the knowledge of early Irish literature depends, is earlier than the 12th century, when the vernacular was already nearer to Modern Irish than to Old Irish. The preservation of the older literature is due to the piety and conservatism of monastic scribes.

All attempts to divide a literature chronologically are of necessity unsatisfactory; but the existence for more than 1,000 years of a literary class in Ireland allows certain landmarks to be established. Four periods may be recognized: (1) the early period, when the literature was composed by the order called *filid* and by churchmen and was preserved in the monasteries; this stretched from the earliest times to the 12th century and linguistically covered the whole field from archaic Old Irish to late Middle Irish; (2) the middle period, when the custody of the tradition passed to the lay and hereditary bardic order; this dated from the middle of the 12th century to the middle of the 17th and is linguistically late Middle Irish and classical Modern Irish; (3) the late period, when both literati and patrons had disappeared and the literature became purely popular and peasant; this continued from the middle of the 17th century until the end of the 19th, and during it the language, at first close to classical Irish, evolved finally into the dialects as they are known today; (4) the revival period, from the end of the 19th century to the present day.

A. Early Period

Irish literature was from the earliest times an aristocratic one, kept in the hands of a professional class, the *filid* (singular *fili*, etymologically "seer"); it has been suggested, with considerable probability, that *fili*, *bard* (originally apparently a lower grade of poet than the *fili*), *brithem* ("judge"), *senchaid* ("historian") and *druí* ("druid") all belonged originally to the same privileged caste. The *druí* was ousted by the Christian clergy, though he is still a prominent figure in the sagas; the other professional orders are ranked by the early laws together with the landowning aristocracy. The status and rewards of the *filid* are also set out—no doubt a necessary provision, for the extravagance of their demands is a recurrent theme and caused them to be severely censured as early as the assembly of Druim Cetta (modern Druim Ceata) in 575. Their duties were to know the sagas and genealogies and to compose encomiastic poems; that is, to serve the past and present glory of the ruling class. This function did not, however, prevent a considerable pride, even arrogance, in their calling, and they could enforce their demands by the threat of the lampoon (*áer*), which could not only take away a man's reputation but also damage him physically and even kill him. The laws set out penalties for the abuse of the *áer*, and the belief in its powers continued up to modern times.

1. Verse.—The earliest verse has not been well preserved, no doubt because of its considerable obscurity. For the official work of the *filid* it is necessary to rely on the fragments in the annals and genealogies and, above all, in the later treatises on metrics, where they often appear in very corrupt form. There are, however, two fairly long pieces in what must be regarded as a poetical style.

The *Fáeth Fiada* ("Cry of the Deer") is a rhythmical incantation traditionally ascribed to St. Patrick; although it is undoubtedly old it can hardly have been composed in the 5th century. There is less doubt about the *Amra* ("Eulogy") on St. Columba (*c.* 521–597); this, couched in rhetorical style, in short sentences linked by alliteration, is ascribed to Dallan Forgaill, who was chief poet (*rígollam*) of Ireland. This device of alliterative rhythmical prose is used again in the sagas, and the technical term for it is a Latin loan word, *retoric*. Probably the oldest metre in the strict sense of the word is that in which two half-lines are linked by alliteration—a system strikingly reminiscent of early Germanic verse. Another pattern that can be discerned is that of a heptasyllabic line with trisyllabic ending; this is found both in legal tracts and in the sagas. Rhyme is found from the 7th century onward. Although it is often a full rhyme, the requirement is only that there should be identity of vowel and syllabic length and that the consonants should belong to the same phonetic class—a system found also in early Welsh. At the same time the quatrain, with seven or eight syllables to the line and rhyme between the second and fourth lines, was derived from Latin hymn metres. Still later are found the first examples of a metre later to become the most popular of all—*debide* (literally "cut in two"); the quatrains consist of two couplets, and the rhyme between the two lines of each couplet is usually that of a stressed syllable with an unstressed one.

The official poetry consists, as must be expected, mainly of panegyric, elegy and similar products of the *fili's* relation to his patron. The incident in *Tromdám Guaire* ("Guaire's Oppressive Guests"), a late satire, where a king is made to say, after hearing a poem, "that is a good poem, for him who could understand it," may contain more than a grain of truth, for the poets often affected a deliberately obscure style, like the Provençal *trobar clus*. Naturally enough, it is their official rather than occasional work which tends to be preserved, but some fragments showing a genuine lyric note have survived to be collected and published in Irish and German by K. Meyer in *Bruchstücke der älteren Lyrik Irlands* (1919).

It must be assumed that the remarkable freedom from dialect variations found in Irish right up to the modern period was a result of the influence of the *filid*, and later the *baird*, but there is no evidence that their language was handed down otherwise than orally until the time when the *filid* are found in the monasteries. The whole written tradition is monastic, and the name of the Christian learning, *légend* (Lat. *legendum*), suggests a contrast in techniques. But from the beginning the church in Ireland not only tolerated but cultivated the vernacular in religious writing, and after the first few centuries it had completely superseded Latin in every field except the purely liturgical.

Religious Verse.—The official verse of the church is hardly more lively than that of the *filid*; for example, the *Félire* or "Calendar" of Oengus, composed about 800 and containing a quatrain for each day of the year. More interesting is the 10th-century *Saltair na Rann* (*Psalter*), a biblical history in 150 *debide* poems, which contains a great deal of strange learning. But it is not these ponderous works which constitute the real glory of Irish religious verse but

rather the personal note heard in the voice of the monk who asks forgiveness for his lapses in meditation, or the nun who asks God to grant her the nursing of the infant Jesus. The anonymous poets who composed such poems as these, as well as the famous address to Pangur, the white cat, were not *filid*, and they avoided the more complicated metres but had the immense advantage of using a language that had been cultivated for many centuries, to which they brought a freshness of insight denied to the *filid*.

Nature Poetry.—The happiest wedding of the literary tradition and religious feeling was in the nature poetry, hardly to be paralleled elsewhere in Europe. The native poetry had already shown, both in the lyrics in the sagas and in the seasonal songs, a remarkable sensitivity to natural beauty; perhaps because some of these were ascribed to Find Fili, later confused with the hero, this type of verse became associated with the Fenian tradition. That the *filid* could adapt their technique to new circumstances is shown by an 11th-century poem on the sea, where the preface, choice of theme and free use of kennings all suggest Scandinavian influence. The monastic movement in the Irish church provided a far stronger impetus to nature poetry. Exile from men, whether beyond the seas or to lonely places in Ireland itself, was held to be a bloodless but meritorious martyrdom, and the bare cells of the hermits brought them very close to earth and sky and their creatures. This almost Franciscan poetry would naturally have an especial appeal to monastic scribes, so that a considerable amount of it has been preserved.

Historical Verse.—Remembrance of the past was an important part of the work of the *fili;* indeed, some of the earliest poems are more metrical genealogy than anything else. As time went on and many texts became obscure and different traditions conflicted, the necessity for compendiums of information grew, and these were often couched in metrical form. They are especially numerous toward the end of the early period. In a long poem, *Fianna bátar i nEmain* ("The Warriors Who Were in Emain"), Cináed ua Artacáin (d. 975) summed up the saga material, while Fland Mainistrech (d. 1056) collected the work of the generations of *filid* who had laboured to synchronize the traditional history of Ireland with that of the outside world as it was then known. Equally important is the great collection, existing both in prose and verse forms, called the *Dindshenchus,* which, as R. Flower has well said, formed "a kind of Dictionary of National Topography, which fitted the famous sites of Ireland each with its appropriate legend." And, indeed, the development of a loose *debide* form, making rhyming easy, produced mnemonic verse on all sorts of subjects—hagiology, grammar, lexicography, metrics and law.

2. Prose.—*The Saga.*—The early Irish epic is a prose narrative, which usually, though not always, contains non-narrative passages in a heightened style, whether *retoric* or verse; these passages often take a dialogue form. E. Windisch first pointed out the resemblance between this and the type of epic found in early Sanskrit sources and suggested that the tradition went back to early Indo-European times. It seems at least to be common Celtic; whatever the date and origin of the poems that make up the Welsh *Gododdin,* they do not constitute an epic, and Sir Ifor Williams has seen in the scattered *englynion* of the early manuscripts the lyrics from an early saga cycle the prose of which has been lost. There are parallels for this in Irish; in the love tale *Liadain and Cuirithir* the prose consists of a few scattered and cryptic sentences, and the famous poem of the *Old Woman of Beare,* the Irish *Vieille Heaulmiere,* may also be a fragment of an old story. This does not imply a common Celtic literature but that the traditions of early storytelling in both languages were similar to what is found best preserved in early Irish. In saying this, the difficulties of interpretation arising from the conditions already mentioned must be remembered. The oldest sagas are in a language that suggests that they were first written down in the 7th and 8th centuries, but these versions probably represent nothing more than the attempts of monastic scribes to fix in writing stories that belonged to an oral tradition. Even these are imperfectly preserved, since there is no extant manuscript evidence earlier than the 12th century. The historical background to this is obvious; the Scandinavian invasions of the 9th and 10th centuries disrupted the entire Irish polity and seriously affected literary studies, as they did everything else. Not until the 11th century did life become sufficiently settled for the works of the past to be collected in the monasteries, and this antiquarian revival was both eclectic and uneven. The great codex *Lebor na Huidre* (*The Book of the Dun Cow*), written early in the 12th century, shows, both in the main text and in the later interpolations, older treatments of the saga material than those found in the *Book of Leinster,* written a few score years later. Only the shortest stories are preserved in forms approximating to the original; the rest abound in doublets, repetitions and conflations because of uncritical editorial handling of earlier material. The rhythmic prose used in the heightened passages of the older stories rapidly became unintelligible and was replaced in later recensions by longer poems in the syllabic metres.

It was the duty of the *fili* to know these stories (*scél*), both primary and secondary. Although in this function he may be described as a *scélaige,* he was really fulfilling the same office as the *senchaid;* that is, the preservation of the glories of the past. Occasionally the authenticity of the *scél* is guaranteed by bringing one of the old heroes into contact with later generations, whether it be the supernatural appearance of Cú Chulainn to St. Patrick, Senchán's evocation of Fergus mac Róig, or Oisín's miraculous survival. Although these stories tend to group themselves in cycles, they range over a period from the earliest fables to the 11th century, and in the catalogues—containing the titles of many stories now lost—they are arranged by type rather than by period, so that the headings are stormings, cattle raids, courtships, battles, voyages and so on.

Whatever the attitude of the storytellers and their hearers to these stories may have been, they must be regarded as almost completely unhistorical as far as personages are concerned; even those that relate to the 7th century usually fail to agree with the more reliable evidence of the annals. It is possible, however, that some of them may contain traditional material capable of historical interpretation. The oldest of them preserve for us a picture of a primitive and pre-Christian state of society—fighting from war chariots, the taking of heads as trophies, the privileged position of the druids, the force of tabu (*geis*) as a supernatural sanction—for which there is little or no evidence from historical sources. They are best paralleled by the classical descriptions of the continental Celts, and the preservation of a memory of them is a result of that conservatism of the Irish literary classes which made a 16th-century bard ignore the bow and the gun alike and send his patron into battle armed only with sword and spear. It is hard to arrive at any convenient division of these stories. The mythological cycle, so called because of the frequent references in some of the stories to immortal beings, cannot easily be separated from the cycle of the kings; all were of equal historicity from the storytellers' point of view and all are equally unhistorical from ours (*see* also Celtic Mythology). The most important cycle is that of the Ulaid, the people who gave their name to the modern province of Ulster. As so often happens, their days of power and influence were long over when the sagas took the form in which they are known today, and the problem of why their tradition especially should have been so much cultivated by the *filid,* and why it should have been so much neglected when the period of the *filid* came to an end, is still unsolved. But certainly the figures of Conchobar, king of the Ulaid; Cú Chulainn, the boy warrior; Medb, queen of Connaught; and Noísi and Déirdre, the doomed lovers, are outstanding both in early Irish literature and, even more, in that of the Anglo-Irish revival, and it is on elements from the sagas of the Ulaid that the nearest approach to an Irish epic was built—*Táin Bó Cúailnge* (*The Cattle Raid of Cooley*).

It is probable that even when first put together, in the 7th or 8th century, the *Táin* was not a very coherent work of art; it must be remembered that the oldest type of *scél* does not exceed a few thousand words and is striking chiefly for the laconic vividness of its narrative and the wit of its dialogue. There is little attempt at construction; the longer stories are no more than a chain of loosely connected incidents. *Táin Bó Cúailnge,* which would appear to be a conscious attempt to provide Ireland with an epic comparable to the *Aeneid,* shows this tendency carried *ad absurdum.* There

are dramatic episodes, such as Medb's dialogue with the soothsayer and Cú Chulainn's dealings with the Connaught scouts, but the long series of single combats becomes wearisome and the story tails off badly. Undoubtedly the finest section is that in which Fergus, an exile from Ulster, recalls for Medb and Ailill the deeds of Cú Chulainn's youth. This story of the boyhood of a hero abounds in convincing touches and is obviously the work of an accomplished artist, and it has been transmitted, by some fortunate chance, in a reasonably correct form. But the *Táin* generally is of less literary interest; its value for the literary historian lies in the fact that, as it was being continually worked over, it provides a kind of stratified record of the degeneration of Irish style. Just as the bare prose of the early period is replaced by bombastic alliterative passages, and the *retoric*, emotive in its obscurity, by longer and longer poems in clumsy *debide*, so the ruthless humour with which Cú Chulainn's early killings are described is replaced by the sentimentality of the fight between him and his boyhood friend Fer Diad.

The *Táin* collected around itself a number of ancillary stories, not the least important of which is that of its revelation to the *filid* in the 7th century by the ghost of Fergus. This may point to the date at which a number of tales of the Ulaid were first combined into an epic. Better known is the tragedy of Noísi and Déirdre, linked through their enemy Conchobar to the Ulster stories. In a modern form it became known as one of the *Three Sorrows of Storytelling*, being linked incongruously with a "mythological" story about the children of Tuireann and a late romance called *Oidheadh Clainne Lir* (*The Children of Lir*). It is, of course, known to the world through the work of the Anglo-Irish school, notably J. M. Synge and W. B. Yeats. Equally full of drama, but not so easily adapted to modern taste, is *Scél Mucce Mic Da Thó* (*The Story of Mac Da Thó's Pig*), which includes such primitive elements as the award of the best portion of meat to the leading champion, the boasting competition which ensues and the resolution of the contest by the production of a head just taken in single combat.

Although the early sagas exaggerate to the point of grotesqueness, there is little trace in them of the supernatural. This can hardly be explained by the monastic origin of the manuscripts; the few attempts to introduce Christian elements are easily detected interpolations, and it is more probable that pagan deities, as such, played comparatively little part in the stories, even in their oldest form. Immortals are found, certainly, especially in the stories ascribed to a period deep in antiquity; the Dagda, Lug, Manannán, Midir and Oengus are all beings of more than human stature, and some of them may, in name at least, be linked with Gaulish and Welsh gods and heroes. But they interfere little in mortal affairs and cannot be said to constitute any kind of pantheon; they live in dwellings (*síd*), which may be mounds or islands but in either case hide them from mortal eyes. In general, mortals may visit the *síd* only at the wish of its occupants, usually because a woman of the *síd* has fallen in love with a mortal man. Life there is eternal, but no mortal can return to the world without taking on the burden of the years he spent in the *síd*. If the pre-Christian Irish had a belief in the immortality of the soul, there is no intimation of it in the sagas.

One of the most delightful of these stories is *Imram Brain* (*The Voyage of Bran*), edited by K. Meyer and A. Nutt (1895), which describes a voyage to Tír inna mBan (the Land of Women). The same plan is followed in other *imrama* (which were to have their ecclesiastical counterpart in the *Navigatio Brendani; see* BRENDAN, SAINT), but the later tales tend to stress the marvelous rather than the supernatural. A story of the *síd* is *Tochmarc Étaine* (*The Courtship of Étain*, edited by O. Bergin and R. I. Best, 1938), which describes how Étaín, once a royal immortal, was reincarnated as a woman and married to Eochaid Airem. Her original husband, Midir, finds her again, wins her from her earthly husband at the gaming board and carries her back to the *síd*, where he holds her in spite of all attempts to rescue her. Nowhere are the unchanging delights of the other world better described than in the songs in which Midir reminds his lost wife of her former home.

Other Early Stories.—In this period stories with an origin outside the recognized tradition began to appear. An obviously exotic element is represented by *Togail Troí* (*The Taking of Troy*) and *The Story of Alexander*, which appear in the oldest saga lists, but the classical learning had comparatively small effect until the next period. The same is true of the stories of Finn; although K. Meyer demonstrated in *Fianaigecht* (1910) that the traditions go back to an early period, their real development was at the time when the *filid* were no longer in control. Later research would indicate that the "wild man of the woods" cycle associated with the name of Suibne Geilt had its origins in Strathclyde, where Irish and Brythonic literature must have been in contact at an early date; this mixture of hagiographical, saga and nature material is one of the most attractive stories of the later period. For a discussion of the Suibne story, *cf.* J. G. O'Keeffe, *Buile Shuibhne* (1913) and J. Carney, *Studies in Irish Literature and History* (1955).

Religious Prose.—Although Irish was used for didactic purposes from the earliest period (one of the most archaic pieces of prose is the fragment known as the *Cambrai Homily*), the material is mostly derived from Latin, and that belonging to the earliest period consists mainly of monastic rules, *exempla* to illustrate a moral and anecdotes about saints. The two latter types often show a style and humour worthy of the professional *scélaige*. At a later stage a number of homilies such as *In Tengae Bithnue* (*The Evernew Tongue*) appear; they are interesting, both linguistically and because their sources are often obscure, but of small literary value. The lives of the saints have little interest, either from the literary or the biographical point of view. Intended, no doubt, to be edifying, they are works of fantasy, incorporating with the passage of time more and more elements from folklore on one side and from the saga material on the other. The emphasis is always on the miraculous; it is the fact that they incidentally contain a great deal of information about everyday life in early Ireland that makes them so valuable today as social documents. Naturally enough, Latin and Irish traditions are mingled in this field, in which the standard works are those of C. Plummer, *Vitae Sanctorum Hiberniae* (1910), and *Bethada Náim nÉrenn* (1922). Another important type of religious work is the vision, the best known example of which is *Fís Adamnáin* (*The Vision of Adamnán*), whose soul is represented as leaving his body for a time to visit heaven and hell under the guidance of an angel. To what extent this type of Irish religious work, found also in Latin, may have influenced Dante is still a subject for speculation. Both the saints' lives and the visions tended to degenerate into extravagance and buffoonery—so much so that parodies on both were composed. The outstanding example is *Aislinge Meic Con Glinne* (*The Vision of MacConglinne*), which describes how a king possessed by a demon of gluttony is cured by the recital of the vision of a land of Cockaigne.

Speculative and Technical Writing.—Theory has always been at least as important as practice in Irish cultural life, and the *filid* built up for themselves a considerable body of academic speculation. Very little has survived, but there are obscure fragments on the nature of inspiration and the origin of language, combined with more practical instructions on matters of metrics and style. At an early stage this learning became interpenetrated with that of Latin, as the collection of texts gathered together under the title of *Auraicept na nÉces* (*The Scholars' Primer*) shows; and a full technical vocabulary was built up to deal with Latin, as well as Irish, grammar. In several very ancient texts the discussion of the art of the poet is mixed with questions relating to his legal status. As early as the 10th century the changes in the language had necessitated glossing and interpretation of the older texts; Cormac mac Cuilennáin, the bishop-king of Cashel (d. 903), compiled a glossary of archaic words with illustrations, etymologies (of the school of Isidore) and illustrative passages.

Just as important to the *filí* as the study of the language and literature was that of history and genealogy. J. MacNeill was the first to point to the immense amount of work that was done in adapting the Latin historical synchronisms to the legends and genealogies of Ireland. A synthetic history of the pre-Christian period was thus built up, and the genealogy of the leading families

carried back to Adam. The sequence of events depicted in a compilation such as the *Leabhar Gabhála* (*Book of Conquests*), with its Milesians, Fomorians, Tuatha Dé Danann and whatnot, has been a fruitful source of speculation to modern archaeologists and historians. Far more reliable are the annals kept in the monasteries from early times; these are generally agreed to be reliable from the 6th century onward.

Law and medicine were both important professions in ancient Ireland. By a curious chance, most of the knowledge of early medicine is due to legal men, for the only surviving material, apart from a few charms, is from legal tracts of the Old Irish period, which deal with the status and responsibility of doctors. No doubt medical knowledge was conveyed orally from master to pupil. The same may have been true of legal studies themselves at first, but there exist texts the language of which clearly shows that they were composed in the earliest period now known. Remarkably archaic in content as well as in language, they no doubt represent several traditions, but chief place was held by the *Senchas Mór* ("Great Old Law Book"), a codification given its authority by ascription to a commission sitting under St. Patrick. This must be regarded as an appeal to history of the same type as was used in the literature, and the real date of systematization must be placed several centuries later. Nevertheless, the oldest strata of the laws are now recognized as providing the best evidence not only of archaic Old Irish but also of social life in early Christian Ireland. The system, however, is merely a description of the legal relationships of a small landowning aristocracy. As life became more complicated, it appears to have broken down altogether, and the judges seem to have given their decisions as simple arbitrators, supporting their judgments with imperfectly understood tags.

B. Middle Period

The 12th century is a period of contradictions. On the one hand, the oldest surviving codices were being written in the monasteries, preserving the literature of many centuries earlier with remarkable fidelity; on the other hand was the gradual rise of a new literary order which, while elaborating the verse forms to a far greater extent than before, at the same time recognized the changes in language that had taken place and codified for poetic use a language that must have been very near the vernacular of the day. After the 12th century the hereditary bardic families became the custodians of Irish literature and continued in that function until the collapse of the Gaelic polity. R. Flower suggested that the bardic movement may have received its impetus during the reign of the centralizing Brian Bóroimhe (Boru) (941–1014), and this may well be true. The conditions were favourable, for the upholders of the older tradition had become almost completely identified with a church which was now doubly threatened by the Norman invasion and by the introduction of new orders of monks from abroad. Also, the language had evolved so far during the unsettled period of the viking raids that the older tradition must have become almost unintelligible; the *Book of Leinster Táin*, for example, swarms with fantastic and, one is tempted to say, unreal linguistic forms. The new bardic families were at first completely divorced from ecclesiastical influence, but soon they were sending their sons into the recently introduced orders, above all the Franciscans, who were to become by the end of this period the greatest custodians of the tradition.

1. Bardic Verse.—The bardic reform of verse was sweeping. The language was brought into conformity with the speech of the time, the large number of metres used by the *filid* was greatly reduced and, in compensation, a greater strictness in rhyme and lavishness in ornament—internal rhyme and alliteration—was insisted on. The scope of the verse became considerably less; the vast bulk that has come down is praise poetry, addressed either to the poet's temporary or permanent patron or to God. This arose naturally from the status of the new order of poets; being no longer associated with monastic foundations, they were dependent entirely upon patronage for the high standard of living which they claimed as their own right, for the bards were no less arrogant than the *filid* whom they replaced. After a course of training which lasted six or seven years, these journeymen poets were free to seek a temporary or permanent patron. It is no accident that they praise generosity as highly as bravery in their poems, which many of the chiefs had copied into family verse books (*duanaire*). There is a considerable monotony in these poems, for, though a chief must be described as victorious, it was considered prudent to avoid mentioning the details, lest the poet should wish to sell a poem to the defeated enemy at some future time. Nevertheless, there is often real poetic feeling in the earlier poems; but by the end of the period many poets were content to string together the clichés evolved through the centuries, with little regard for meaning as long as the metre was correct.

Modern taste finds little of interest in even the best of the official bardic poetry; it is the handful of occasional verse that survives that shows real worth. One of the earliest poets of the great bardic family of Ó Dálaigh, Muireadhach Albanach (*c.* 1214–40), has left, as well as a stirring defense of his action in killing a tax collector, an elegy on the death of his wife which is unsurpassed in Irish literature. Such gems are rare.

A new note was brought into Irish literature by the Gaelicized Norman invaders, that of the *amour courtois* or courtly love, and the combination of this exotic element with the wit and felicity of the bardic style has left a number of enchanting poems. No doubt there were once many, many more than those collected by T. F. O'Rahilly in *Dánta Grádha* (1926), but it was only by a fortunate chance that precious vellum was devoted to the preservation of such frivolities. A different kind of departure from praise poetry is the *crosánacht*, a poem in which the verse is frequently interspersed with humorous or satirical prose passages.

2. The Fenian Cycle.—The vast bulk of native prose of this period is concerned with the hero Finn and his war band (*fían;* hence "Fenian"). In spite of their comparative neglect in the 12th-century manuscripts, the stories about Finn, Oisín, Caoilte and the rest must have existed among the people for many centuries. J. MacNeill may be right in seeing in them the traditions of a subject race, for the proportion of folklore elements in them is far higher than in the aristocratic Ulster cycle. The outstanding work is *Agallamh na Seanórach* (*The Interrogation of the Old Men*), in which Oisín and Caoilte are represented as surviving the battle of Gabhra and living on until the time of Patrick, whom Caoilte accompanies through Ireland, explaining to him the origin of the names of the places which they visit—a technique no doubt borrowed from the older *Dindshenchus*, as is also the form of prose with verse passages. But whereas in the Ulster cycle the introduction of the hero of former times is merely a way of authenticating the story, in the Fenian stories it is used to introduce a note of nostalgia for past glory, so that in modern speech "Oisín after the Fianna" is the type of the survivor of a heroic period. No doubt this contrast reflects that between an old hierarchical society and one facing a rapidly changing and hostile world. The Fenian stories never received such careful literary treatment as did those of the older tradition, and the old form was soon abandoned for prose tales and ballads—the latter something of an innovation in Irish literature, though there are examples of metrical versions of prose sagas even in the Ulster cycle. The prose tends to degenerate into a bombastic and alliterative style, seen at its worst in *Cath Fionntrágha* (*The Battle of Ventry*). There are echoes of this style in the "runs" of the modern folk tale, where the Fenian tradition is supreme. The ballads are easier reading and may be regarded as the beginnings of popular, as opposed to professional, literature in Irish. The metres represent such a drastic simplification of the bardic technique that versification became even easier than in the English ballad, and a distinct change in theme can be seen as this literature passed into the hands of the people. St. Patrick still makes his appearance, but he is now a malevolent and hostile figure, starving and bullying the aged heroes who represent the pagan and warlike tradition. These ballads had an immense popularity among the common people; the collection made by James Macgregor, dean of Lismore, early in the 16th century, shows that the tradition of ballads about Oisín and Finn, on which James Macpherson (*q.v.*) was later to base his forgeries about Ossian and Fingal, was already flourishing.

3. Other Prose.—Retellings of the stories popular with the *filid*

of course continue to be found, but these steadily dropped out of favour. Sometimes they were combined with folk-tale elements, as was the case with the very old saga of Fergus mac Léti, which was rewritten, perhaps in the 14th century, to include a story of a people of tiny stature—the leprechauns of folklore. It has been suggested that Jonathan Swift may have heard some version of this and incorporated it in his *Gulliver's Travels*. A curious example of a saga technique being applied to a great historical personage is the *Cogadh Gaedheal re Gallaibh* (*The War of the Irish With the Foreigners*), which deals with the wars of Brian Bóroimhe; the style is bombastic and inflated, and it was to find many imitators, of which probably the worst is Lughaidh Ó Cléirigh's *Life of Aodh Ruadh Ó Dómhnaill*. Most important of all, a flood of translations from both Latin and English began. The stories of Marco Polo, Sir John Mandeville, Prester John and Guy of Warwick, as well as classical and Arthurian stories in their medieval adaptations, became well known in Ireland. The new religious orders were responsible for the translation of many spiritual and devotional works. There was also a considerable amount of technical writing. On the native side, the most important was the grammatical and metrical teaching which was set out in many elaborate tracts, giving examples of correct and incorrect usage. Legal science appears to have been moribund. From abroad came translations of medical tracts in large numbers. Continental teaching seems completely to have superseded the native tradition during this period. The churchmen made the experiment, remarkable for the time, of handling philosophical material in the vernacular; unfortunately very few of these tracts are extant and almost nothing has been published.

By the 15th century the printing press was beginning to make literature available to larger numbers in most European countries. In Ireland, however, in spite of the fact that Irish was the language of most of the country and that the literature was flourishing at that period, there was one fatal obstacle; the Irish did not control the towns, and so had no access to printing. Irish literature perforce remained an aristocratic one, the preserve of those who could afford to maintain the literati and supply them with the costly vellum, which was not replaced by paper until the end of this period. It is easy to understand that this literature had little effect on the masses of the people.

C. Late Period

It was during the reign of Elizabeth I that English policy first succeeded in breaking the power of the Irish and Anglo-Irish nobility, and the process was completed by the middle of the 17th century. The emigration or dispossession of this nobility entailed also the disappearance of the bards who were at once its dependents and propagandists—a fact well known to the English power, which persecuted the "rhymers" bitterly. Their eyes fixed on the past, the bards had shown no sign of interest in the renaissance of learning going on elsewhere; with their elimination the old tradition itself was doomed, and there were no learned men to found a new one. Indeed, from this time onward the Irish language itself began to slip from its position as the common speech of the country.

1. Verse.—The poets did not give up without a struggle. In the early part of the 17th century they were engaged in a long and heated poetic debate on early Irish history, and the tradition was to survive in Scotland, together with the native aristocracy, until after the 1745 rebellion. But bardic language and diction, unchanged for more than 400 years, were too difficult for poets who had not undergone the strict discipline of the schools. Without patrons the schools soon died, and hardly any correct bardic verse was written in Ireland after 1650. But just as the bards had taken over from the *filid* 500 years before, so a new school of poets took over from the bards. And just as the bardic measures had been in preparation for centuries before they established themselves as canonical, so the song metres which replaced them had existed for centuries among the people, though rigorously excluded from the vellums. The new poets abandoned the syllable counting by lines with a fixed number of stresses; the stressed vowels rhymed in patterns which might be very simple or, later, bewilderingly intricate, but simple vocalic assonance took the place of the earlier rhyme. The language of poetry moved consistently toward the language of the people, and this, combined with the freedom of the new metres, allowed the poets to speak with a new vigour. While they had little patronage, there was at least an increasing supply of paper, so that their works, still barred from the printing press, were able to be circulated freely among the literate. Naturally enough, the tone of verse throughout the 17th century was one of passionate defiance of the new regime. In it is found the first coherent expression of patriotism conceived as devotion to an abstract ideal rather than as loyalty to an individual—a concept of considerable importance in the later history of the country. But it must be admitted that much of the verse of this period represents a mere nostalgia for the past, the vain regrets of men who had been forced to exchange the pen for the spade.

By far the greatest of the poets of the song metres was Dáibhidh Ó Bruadair, who died at the end of the 17th century (works edited with translation by J. MacErlean, 1910–17). Ó Bruadair and Ó Raithile, of slightly later date, still had some patrons. After them the poetic tradition, while remaining, in Munster at least, extraordinarily subtle in craftsmanship, was preserved only among the common people and ceased to have any contact with reality, as the *aisling* ("vision") poetry, singing a Jacobite restoration, sufficiently demonstrates. But it had real vigour in such themes as satire and *pastourelle*, and these peasant poets maintained the literary tradition until the end of the 18th century. The last magnificent flowering of the Munster tradition was *Cúirt an Mheánoíche* (*The Midnight Court*), written by Brian Merriman, a Clare schoolmaster (translated by Frank O'Connor, 1945). Perhaps the best-sustained poem in Irish, it is an exercise on traditional themes, such as that of the *mal mariée*, in a metre that is an ingenious and successful adaptation of the heroic couplet to the Irish style. After it, Irish poetry became a matter of folk songs, and even these were produced less and less after the crushing blow inflicted by the great famine (1846–47) (*see* Ireland: *The Great Famine*).

2. Prose.—During the 17th century the tradition continued to produce a good deal of prose, mainly antiquarian and of inestimable value today, for the writers were able to draw on many sources now lost. By far the most important is *Annála Ríoghachta Éireann* (*The Annals of the Four Masters*), a compilation of all the available material on the history of Ireland to 1616, made under the direction of the Franciscan lay brother Michael O'Clery. Less readable, but also of great historical importance, are the genealogies compiled by Dubháltach Mac Fir Bhisigh. Geoffrey Keating (*c.* 1570–1646), who wrote a dignified yet simple prose based on the bardic language, produced the first historical (as opposed to annalistic) work in Irish in his *Foras Feasa ar Éirinn* (edited with translation by D. Comyn and P. Dinneen, 1901–08), as well as some fine verse in both the old and the new metres, and two spiritual treatises. A number of religious works, printed by the Irish Franciscans in Louvain, were smuggled into the country; it is significant that manuscript transcripts are more numerous today than printed copies. The earliest book to be printed was the Protestant translation of the New Testament (in 1603), but for obvious reasons this has exerted little influence.

An interesting development in prose style was the satire called *Páirliment Chloinne Tomáis* (*Parliament of Clan Thomas*), in two parts, probably of different authorship, one written before, one after, the Cromwellian wars. It appears to have been written by a representative of the bardic order, for it attacks with equal savagery the new ruling class and the native peasantry, using a style very close to that of the earlier *crosánacht*, but with the prose now predominating over the verse. It found several imitators, but the old tradition was by this time too attenuated for so aristocratic an attitude to be maintained.

The imaginative prose of the paper manuscripts was in general of a much more popular kind; it consisted mainly of developments of the Fenian themes or of romances in which themes drawn from Irish and foreign medieval literature were freely mingled with folklore and *fabliau* elements. As in the case of the song metres, there is reason for believing that these romances had a consider-

able tradition behind them before they appeared in writing. They were the form in which the people assimilated the literature circulating among the aristocracy. The circumstances of their transmission have caused a considerable divergence in the forms in which they are found; it may be for this reason that comparatively few of them have been published, let alone studied. With a public growing steadily more apathetic and less able to read Irish, there could be little hope for prose production. During the 18th and early 19th centuries the only books printed in Irish were a few catechisms and devotional tracts. The manuscript tradition was carried on by a few devoted scribes into the first half of the 19th century, when it all but died out. By the middle of the century there was no literary activity in Ireland and all but a handful of the speakers of the language were illiterate in it.

D. The Gaelic Revival

An antiquarian interest in the Irish language and its literature had begun early in the 19th century, and the publications of J. Hardiman, J. O'Donovan and E. O'Curry, especially the last-named's *On the Manners and Customs of the Ancient Irish* (1873), had caught the imagination of many of the educated classes, whose language of culture had for centuries been English. The Young Irelander Thomas Osborne Davis was probably the first to see how the restoration of the Irish language could be made a political force in a national movement, but the increasing interest remained for a time academic and did not turn to discussion of measures for the preservation or extension of the speaking of Irish until the establishment of the Gaelic league in 1893. This movement had its counterparts in every European country from Catalonia to Finland, but there were difficulties in Ireland unparalleled elsewhere.

The speakers of Irish had sunk to the status of a minority and, worse still, since the language of Irish nationalism had been English for more than 200 years, neither they themselves nor their English-speaking fellow countrymen looked on Irish as a prerequisite of separate nationhood. The curious result was that the revival in Irish came from the enthusiasm of antiquarians and nationalists, few of them Irish-speaking in origin, rather than from the Irish-speaking peasants themselves—a situation which still exists to some extent. The culmination of the revival movement was the situation in the Republic of Ireland, where Irish and English enjoy equality before the law and all schoolchildren must reach a given standard in both languages.

The revivalists were faced with a grave difficulty when they came to face the problem of writing a language that had lost its old standard and had split up into dialects. The classical bardic language was too archaic to be restored, and no Ivar Aasen or V. S. Karadžić came forward, as in Norway and Serbia, to form a new language on the base of the dialects. The inevitable result was that native speakers and learners alike wrote the language of their native or adopted parish, a situation that continued, although by the middle of the 20th century a standard evolved by government departments was being increasingly accepted. This might have happened naturally had there been more speakers in the province of Munster, where the literary tradition was best preserved. It was a Munster priest, Father Peter O'Leary, who gave impetus to the revival with a stream of novels, essays and translations of all sorts, and it was a Munster fisherman, Tomás Ó Criomhthain, who produced the finest book of the revival in his *An tOileánach* (*The Islandman;* translated by R. Flower, 1934). In the Ulster dialect there was some good writing by Séamus Ó Grianna ("Máire") and his brother Seosamh Mac Grianna. Connaught produced three good short-story writers in Pádraic Ó Conaire, Máirtín O Cadhain and Liam O'Flaherty (who also wrote in English).

In general the short story is the most successful as well as the most popular form. The novels demonstrate the national inability to handle the longer and more complex forms. The drama, lacking large urban audiences, consists mainly of translations and although some sensitive lyric poetry has been produced, notably by Máirtín Ó Direáin and Máire Mhac an tSaoi, no poet of Yeats's stature has emerged. (D. Ge.)

II. ANGLO-IRISH LITERATURE

It is impossible to dogmatize, as some have tried to do, about the limits of Anglo-Irish literature. It is enough to exclude on the one hand writers of Irish descent who have no direct connection with the country, such as the Brontë sisters, Edward FitzGerald, Edgar Allan Poe, Eugene O'Neill and T. E. Lawrence; and on the other, English writers domiciled in the country for a considerable time and showing decided traces of this in their work, such as Edmund Spenser and Anthony Trollope. Hard and fast boundaries cannot be drawn between a distinctive Irish literature in English and the contribution of Irish writers to English literature. The difference may be a real one, but it is too vague and uncertain to be taken into account here. The one type of writing merges into the other. All must count as Anglo-Irish literature, in whatever country and for whatever public it was originally produced. As to what constitutes an Irishman, one can only fall back on birth, early training and habitual residence.

1. The Beginnings.—Irish people take readily to writing in any language, perhaps more readily than they do to reading. Ireland's total output of literature must be enormous. It is therefore perhaps surprising that the first products of Anglo-Irish literature were so inconsiderable. It must, however, be remembered that until the 17th century the language of Ireland was Irish. The so-called Anglo-Irish were a small colony, a garrison holding a perilous outpost, constantly yielding linguistic as well as physical ground to the resurgent Gael; and even among the colonists English had to struggle for supremacy with Latin and French. A few manuscripts have survived, showing the existence of a vernacular poetry of no great originality or distinctiveness. The most striking example is the 13th-century satire *The Land of Cockaygne;* but it is hard to say if any work lacking local allusions was originally composed in the country.

The first notable Irish writer in English was Richard Stanyhurst, who contributed sections dealing with Ireland to Raphael Holinshed's *Chronicles* (1577) and attempted to write English quantitative verse on Latin models, with extraordinary results. From this time on, as the colony grew in numbers and importance and the conquest of the whole country was seriously attempted, the stream of Anglo-Irish writing began to swell, and gradually Gaelic as well as English names began to appear. In the next century there were Sir John Denham, author of the much admired *Cooper's Hill* (1642) and one of the pioneers of a smoother and more regular versification, Lord Roscommon (*c.* 1630–85), Nahum Tate (1652–1715) and Nicholas Brady (1659–1726) among minor poets; Lord Orrery (1621–79) among minor dramatists; and Sir John Temple (1600–77), father of the more famous Sir William, who may be mentioned among minor historians. But there was as yet no major name.

2. The 18th Century.—Writers of the first rank did not appear until the establishment of English as the predominant language, after the overthrow of the Gaelic culture and the arrival of hordes of new immigrants who were not so easily absorbed as their predecessors had been. But from then on, Irish writers of English were among the great. The first of these was Jonathan Swift. Irish-born of English parents and educated wholly in Ireland, he became a dominant literary figure in England. He returned to Ireland unwillingly as dean of St. Patrick's cathedral, Dublin, to become the idol of Ireland for his championship of a people he hated and loved, as he hated and loved all humanity, and to end as one of the great names in the literature of the world. Swift to the world at large means *Gulliver's Travels* (1726). Ireland has rather remembered his tracts on its own wrongs, such as the *Drapier Letters* (1724), among the first of a long series of such writings by Irishmen, which raised pamphleteering to the status of literature.

Nor does the dean stand alone at the beginning of the century. If Swift made politics literature, his friend George Berkeley, bishop of Cloyne, wrote philosophy which, apart from its importance in the history of human thought, is almost as admirable from the purely literary point of view as that of Plato. And it must not be overlooked that Bishop Berkeley was a convinced and admitted Irishman and a lover of his country, about whose welfare he ex-

pressed strong views in his *Querist* (1735–37).

Drama.—Perhaps the greatest contribution of Ireland to the literature of the English language has been neither in philosophy nor in politics, but in drama, especially comedy. Where would the English theatre be without William Congreve, George Farquhar, Oliver Goldsmith, Richard Brinsley Sheridan, Oscar Wilde and George Bernard Shaw? The first permanent theatre was established in Dublin in 1662, and from then on the swarms of Irish-born dramatic authors, both of native and of English stock, as well as of actors and managers, who established a reputation both in Ireland and in England defies enumeration. Here we are concerned only with the authors. Congreve, English-born but entirely Irish in rearing and education, is the greatest name in English Restoration comedy. Farquhar, coming from the north, though of Gaelic origin, has a gaiety and humanity all his own. Passing over Sir Richard Steele, a sentimental dramatist who is better-known as an essayist, and Thomas Southerne, a tragedian, we come to Goldsmith, who touched nothing that he did not adorn, or who was, if one prefers it, jack of all literary trades though perhaps entirely master of none, and who was the author of one supreme comedy, *She Stoops to Conquer,* said to be based on his own early experiences in County Longford. There were many successful minor Irish dramatists, including Arthur Murphy (1727–1805) and Hugh Kelly (1739–77), but their plays were the common repertory of the English-speaking theatre of the time. The few plays written especially for Irish consumption were of no particular merit.

Poetry and Prose.—Turning to poetry, mention must be made again of Swift and Goldsmith, and Thomas Parnell (1679–1718), a melancholy though not unpleasing poet, chiefly remembered for his "Nightpiece on Death," must not be forgotten. There were some minor poets, but on the whole Anglo-Irish poetry did not flourish till the romantic movement. As for prose, the novel was only just coming into existence. Goldsmith produced a major work in *The Vicar of Wakefield* (1766). Laurence Sterne was born in Ireland, though he did not live or work there. Political eloquence in those days grew into literature. Edmund Burke was a political philosopher and an orator whose speeches read better than they sounded. Sheridan was as great a parliamentary speaker as he was a dramatist. No less notable was the eloquence of John Philpot Curran (1750–1817), and some of the speeches on Irish themes by Henry Grattan (1746–1820) are among the greatest of their kind.

3. The 19th Century.—With the 19th century came a change. The old, conquered Ireland, prostrate for so long, was beginning to rise to its feet. The Anglo-Irish colony, too, was gaining self-confidence and feeling itself a distinct entity. Nationalism, liberalism and revolution were in the political air, while romanticism was beginning to affect the arts. Moreover, antiquarianism had begun to uncover the Gaelic past. This had never been wholly forgotten; even Dean Swift had translated a poem from the Irish. But Charlotte Brooke (1740–93), the daughter of Henry Brooke, himself a dramatist and novelist, was the first to make verse translations on a more extensive scale, and soon there were others. Native Irishmen and settlers alike began to feel a new interest in their country. Irish nationality, as it is known today, was born. Until this time there were for the most part merely books by Irish authors; thenceforth books about Ireland predominated. Of such books an enormous number was produced. The romantic movement and the discovery of Ireland's ancient tradition provided an incentive. Irish literature in English became more plentiful and more distinctive than ever before.

Poetry.—For the first time poetry came to the forefront. Anglo-Irish verse was definitely established by Thomas Moore. Moore was a most versatile poet and a singer of his own songs. In his *Irish Melodies* (1808–34) he attempted to solve the problem of setting English words to Irish airs, which was not so easy as it sounds. The result may not please the purist in folk song, but it was very singable as well as good poetry; as the matter of the songs was Irish, often vehemently so, the wrongs of Ireland were warbled in English drawing rooms with great ultimate advantage to the Irish cause. Nor did Moore's own people fail to appreciate him; he was a national hero as no other Irish poet has been. Quite apart from his songs, his oriental epic *Lalla Rookh* (1817) brought him wealth and fame.

Moore wrote in English. In order to be Irish, he did not think it necessary to write in dialect or to attempt the style of folk poetry, as did some of his contemporaries, such as J. J. Callanan (1795–1829), who wrote very free adaptations from the Irish. Another contemporary, however, George Darley (1795–1846), wrote in a most exquisite and scholarly style, and his work was mistaken for that of an Elizabethan or 17th-century poet. A slightly earlier writer was the Spenserian poet Mary Tighe (1772–1810), much admired in her own day, and with good reason, for her *Psyche* (1805).

In 1842 the patriotic organization known as Young Ireland, led by Thomas Osborne Davis, an eloquent and sincere writer in prose and verse, founded a new paper, the *Nation.* A large number of poets and prose writers attached themselves to it. Besides Davis himself, who died young and regretted in 1845, poets of merit were Thomas D'Arcy McGee (1825–68), Richard D'Alton Williams (1822–62) and Lady Wilde (1826–96). Another notable journal of the time was the *Dublin University Magazine,* which lasted for about 40 years and was probably the finest magazine ever produced in Ireland. Its politics were the direct opposite of those of the *Nation,* but it was mainly literary, and most of the best Irish writers contributed to it. Of its poetical contributors the most notable was James Clarence Mangan, an enormously prolific and most uneven writer of every kind of verse, including numerous translations from languages which he probably did not know of poems which did not exist. At his best, when inspired by his love of Ireland or by his own miseries, due largely to alcohol, he was one of the greatest poets of Ireland. He was much influenced by the German romantics and in turn influenced Edgar Allan Poe. Another notable poet was Sir Samuel Ferguson (1810–86), who wrote on Irish themes in a strikingly original way, inspired to some extent by Gaelic examples. Among other poets of a very poetical time were Denis Florence MacCarthy (1817–82) and Aubrey de Vere (1814–1902), who were more typical of their period. William Allingham wrote poems in ballad style and a long and interesting narrative in verse, *Laurence Bloomfield in Ireland* (1864). He later settled in England and became an associate of Dante Gabriel Rossetti. He adopted the Pre-Raphaelite manner, which links him with W. B. Yeats and the next period of Irish writing.

Prose.—Among novelists was Charles Maturin, whose *Melmoth the Wanderer* (1820) had a wide influence in Europe. Even better known was Maria Edgeworth, who in the course of a long and busy life produced many novels, always with some edifying tendency but none the worse for that. She knew well the Ireland of her day and depicted it with insight and humour in *Castle Rackrent* (1800) and in the tale *The Absentee* (1812). A landlord's daughter, she believed firmly that the solution of Ireland's troubles lay in the improvement of the outlook of its landlords. Novelists who wrote of country life mainly from the point of view of the tenant were William Carleton, a powerful storyteller though a poor stylist, whose masterpiece is *Fardorougha the Miser* (1839); and the immensely popular Charles Joseph Kickham, poet, Fenian and political convict, whose *Knocknagow* (1879) was for long Ireland's favourite reading. Other novelists of rural life were Gerald Griffin (1803–40) and the brothers John and Michael Banim. Lady Morgan wrote *The Wild Irish Girl* (1806) and other novels.

William Hamilton Maxwell (1792–1850) wrote lively stories dealing largely with sport. He inspired the better-known Charles Lever (1806–72). Lever, at one time editor of the *Dublin University Magazine,* wrote a long series of novels, lively and interesting, though often careless. He knew Ireland well and could write seriously enough of Irish matters; but as some of his best-known work is broadly humorous, he has been unjustly accused of ridiculing the nation. Another humorous writer, often mentioned with Lever though not his equal, was the versatile Samuel Lover (1797–1868).

Joseph Sheridan Le Fanu was a successful writer of a different kind. Owner and editor of the *Dublin University Magazine* in the

1860s, he wrote many novels and short stories, chiefly dealing with mystery, crime and the supernatural. He was perhaps the greatest Irish master of the ghost story. *In a Glass Darkly* (1872) contains the best of his work of this kind. *Uncle Silas* (1864) is his finest novel. He was also a poet, and there is a poetic quality about all his work which raises it far above the commercial thriller.

John Mitchel, author of the *Jail Journal* (1854), W. E. H. Lecky, the historian (1838–1903), and Edward Dowden, the critic (1843–1913), were all outstanding 19th-century writers in their several ways. Only the drama produced no great name.

4. The Literary Renaissance.—Toward the end of the 19th century a new movement in Irish literature became apparent. In fact, such changes came over literature everywhere. In the 1890s two Irish dramatists appeared, the first for a century: Oscar Wilde, son of Sir William Wilde, a fine writer on Irish antiquities, and Lady Wilde of the *Nation;* and George Bernard Shaw, who was two years younger than Wilde and outlived him by 50 years. Neither wrote of or for Ireland, but they were outstanding Irish dramatists in the old Anglo-Irish tradition. Perhaps they were the last of their kind; for a definitely Irish theatre was now arising, as part of a new, consciously Irish literary movement, known as the Irish literary renaissance.

The movement, which was closely allied with a new and strong political nationalism and with a revival of the Irish language, centred from the first around the greatest Irish poet, William Butler Yeats, Pre-Raphaelite, theosophist, modernist, but always a thorough Irishman. Though be contributed to the foundation of the first Irish theatre, the Abbey (*see* ABBEY THEATRE), his own dramas were few. He wrote some beautiful plays, but they were not easy to produce. His chief colleague at the Abbey was Lady Gregory, who not only took a leading place in the management but also contributed many plays, mostly peasant comedies. The greatest dramatic name of the movement was that of John Millington Synge, who wrote in a peasant dialect, largely of his own invention. His plays have great beauty and power, and his early death was an irreparable loss to Irish drama. Later, the theatre, founded for poetry and noble speech, became absorbed in realism, mostly rural realism. Lennox Robinson and T. C. Murray were the most important of the realists, and Sean O'Casey replied to peasant realism with his brilliant and moving dramas of the Dublin slums beginning with *The Shadow of a Gunman* (1922). Subsequently he left Ireland and attempted a kind of symbolical drama with less obvious success. Later dramatists continued to supply plays to the Abbey and its younger rival, the Dublin Gate theatre, and most modern Irish writers occasionally attempted drama. St. John Ervine wrote successfully for both the Irish and English theatres.

In poetry, besides Yeats, there was George Russell (Æ), mystic, patriot and agricultural reformer, who left a large quantity of beautiful if rather vague verse. Notable among their younger contemporaries were Padraic Colum, Austin Clarke, Seumas O'Sullivan (James Sullivan Starkey), F. R. Higgins and Oliver St. John Gogarty. The Republican movement which led to Irish independence had its poets, P. H. Pearse, Thomas Mac Donagh and Joseph Mary Plunkett, all executed in 1916 after the rising on Easter Monday of that year; and a strong sympathizer in Francis Ledwidge, a rural lyricist, who was killed in 1917 fighting for England in World War I. A writer who went his own delightful way was Lord Dunsany (1878–1957). He was not only a poet but a prolific and successful writer of novels, plays and short stories.

In the realm of the novel were the historical tales of Emily Lawless (1845–1913) and Standish James O'Grady (1846–1928), while Canon P. A. Sheehan (1852–1913) presented aspects of Irish life through the eyes of an Irish priest. By way of contrast there was George Moore, an imitator of French naturalism, who suddenly attached himself for a time to the Irish cultural movement; his delightfully impudent account of its leading figures in *Hail and Farewell* (1911–14) is on the whole more readable than his overcarefully written novels. James Stephens (1882–1950) wrote fanciful stories as well as verse of great charm. The excellent novels of E. Œ. Somerville (1861–1949) and Martin Ross (Violet Florence Martin; 1865–1915), some humorous, some tragic, must also be mentioned. But all of these are overshadowed by the amazing productions of James Joyce, who made himself and Dublin famous throughout the world and is without doubt one of the most significant literary figures of the 20th century.

5. The Moderns.—Of the writers born about 1900, Liam O'Flaherty produced a new and more violent type of fiction, stripping away many of the illusions which enveloped Irish writing, but probably creating a few of his own. When he was not writing sensationally for sensation's sake, his novels and stories were full of power. Brinsley MacNamara (A. E. Weldon), also a dramatist, wrote tales of the quiet midlands which were original and interesting. Frank O'Connor began as a poet, earned distinction as a novelist, but later wrote mainly short stories and articles. Sean O'Faolain was equally versatile. His biographical works are outstanding. Elizabeth Bowen and Kate O'Brien were popular women novelists. Their older contemporary, Stephen Gwynn (1864–1950) excelled in biography, history and many other kinds of writing.

See also ENGLISH LITERATURE and the other general articles mentioned there; there are also articles on most of the writers referred to above. *See* also references under "Irish Literature" in the Index. (LD.)

BIBLIOGRAPHY.—*Gaelic Literature: General works:* The older period is covered by R. I. Best, *Bibliography of Irish Philology and of Irish Printed Literature,* vol. i (1913), vol. ii (1942); the literature of the revival period is dealt with by R. de Hae and B. Ni Dhonnchadha, *Clár Litridheacht na Nua-Ghaedhilge, 1850–1936,* 3 vol. (1938–40). There is no adequate history, A. S. de Blácam's *Gaelic Literature Surveyed* (1929) being merely a popular account. For the first two periods R. Flower, *The Irish Tradition* (1947), and M. Dillon, *Early Irish Literature* (1948), are authoritative studies. The most important periodicals are *Zeitschrift für celtische Philologie* (later *keltische*) (1896 *et seq.*); *Revue celtique* (1870–1934), continued as *Études celtiques* (1936 *et seq.*); School of Irish Learning, *Ériu* (1904 *et seq.*); National University of Ireland, *Eigse* (1939 *et seq.*); *Celtica* (1950 *et seq.*).

Early period: J. Vendryes, "L'Ecriture ogamique et ses origines," *Études celtiques,* vol. iv (1941); K. Meyer, *Selections From Ancient Irish Poetry* (1913), *Learning in Ireland in the Fifth Century* (1913); M. Dillon, *Cycles of the Kings* (1946), *Early Irish Society* (1954); K. Jackson, *Studies in Early Celtic Nature Poetry* (1935); T. F. O'Rahilly, *Early Irish History and Mythology* (1946); R. Thurneysen, *Die irische Helden-und Königsage* (1921); D. A. Binchy, "The Linguistic and Historical Value of the Irish Law Tracts," *Proceedings of the British Academy,* vol. xxix (1943); D. A. Binchy (ed.), *Studies in Early Irish Law* (1936); G. Murphy, *Saga and Myth in Ancient Ireland* (1955), *Early Irish Lyrics* (1956).

Middle period: E. Knott, *Tadhg Dall Ó Huiginn* (1922–26), is the best study of bardic system and technique. *See* also E. C. Quiggin, "Prolegomena to the Study of the Later Irish Bards," *Proceedings of the British Academy,* vol. v (1913); P. Walsh, *Irish Men of Learning* (1947).

Late period: D. Corkery, *The Hidden Ireland,* 2nd ed. (1925); G. Murphy, "Notes on Aisling Poetry," *Eigse,* vol. i (1939); J. H. Delargy, "The Irish Storyteller," *Proceedings of the British Academy,* vol. xxxi (1945).

Revival period: The best appreciation is M. L. Sjoestedt-Jonval, "La Littérature qui se fait en Irlande," *Études celtiques,* vol. ii (1936 *et seq.*). (D. GE.)

IRISH MOSS (CARRAGEEN or KILLEEN), the name applied especially to the red alga *Chondrus crispus,* a small, tufted seaweed with thin fronds from two to ten inches long that grows abundantly along the rocky parts of the Atlantic coast of the British Isles, Europe and North America. The term is also used loosely for several other red seaweeds found associated with *Chondrus,* among which are a few species of *Gigartina.* Other names, expressive of the appearance of these seaweeds, are pearl moss, lichen, curly moss and jelly moss. In its fresh condition the plant is soft and cartilaginous, varying in colour from a greenish yellow to a dark purple or purplish brown; but when sun-dried and bleached it has a yellowish, translucent, hornlike aspect and consistency.

The principal constituent of Irish moss is a gelatinous substance, carrageenin or carrageen extract. Carrageenin for commercial use is extracted by boiling dried Irish moss.

In Europe, Irish moss used for the extraction of carrageenin is obtained from plants cast ashore. In the United States it is collected from shallow water and dredged with special rakes. Commercially, carrageenin is used chiefly as an emulsifying and suspending agent in pharmaceutical and certain food products. *See* ALGAE: *Utilization of Algae.* (G. M. S.; X.)

IRISH SEA, the area of water lying between Ireland and Britain, is connected with the Atlantic ocean by the North channel between County Antrim and Scotland (minimum width between Fair head and the Mull of Kintyre, 13 mi.) and by St. George's channel (minimum width between Carnsore point and St. David's head, 47 mi.). If St. George's channel is taken to include the whole area south of a line from Dublin to Anglesey, the Irish sea is roughly square, measuring about 100 mi. from north to south and 125 mi. from west to east. It is bounded by Scotland on the north, England on the east, Wales on the south and Ireland on the west. In the centre is the Isle of Man.

The sea is relatively shallow (less than 30 fathoms) in the eastern half, but there is an elongated trough between the Isle of Man and Ireland with depths reaching to more than 70 fathoms. The mean tidal range is 20 ft. on the Lancashire coast, 14 ft. around the Isle of Man and 10 ft. on the Irish coast between Strangford lough and Drogheda. Because of the semienclosed nature of this sea and the consequent small waves generated therein, much of the coast is low lying and composed of nonresistant materials such as boulder clay. In south Lancashire is one of the most extensive areas of sand dunes and one of the widest beaches at low tide to be found in Britain.

The estuaries are all partially drowned river mouths and afford evidence of the postglacial rise in sea level. Morecambe bay is largely infilled with sand, across which the incoming tide sweeps at high speed. Inland of most of the present coastline there is evidence of a postglacial sea level about 20 ft. higher than at present, with abandoned cliffs, infilled estuaries and raised beaches. (R. K. GR.)

IRKUTSK, an *oblast* in the Russian Soviet Federated Socialist Republic of the U.S.S.R., was formed in 1937. It covers an area of 296,486 sq.mi. in eastern Siberia. Lake Baikal lies along its eastern boundary and the Angara, the lake's outlet, crosses the *oblast.* A northward extension of Irkutsk occupies the upper valley of the Nizhnyaya Tunguska, while in the east is the upper part of the Lena basin. Most of this huge area consists of the rolling hills and broad valleys of the Central Siberian plateau and its eastern extension, the Patom plateau (Patomskoye Nagorye). In the south the *oblast* extends to the crest line of the Eastern Sayan mountains. Most of the region is covered by dense taiga coniferous forest, dominated by Siberian and Dahurian larch, with pine, stone pine, fir and spruce, the last two more especially on higher areas. Only in the south are there one or two small patches of forest-steppe and steppe. Soils are poor podsols, nearly everywhere underlain by permafrost. Climate conditions are very strongly continental.

Irkutsk has an annual temperature range of about 39° C. (70° F.). Winters are long and exceptionally cold, especially in the north and east, and summers are hot. Precipitation is low, about 12–14 in. a year. Thus the protective snow cover is thin and is often entirely swept away by strong winds.

The population, at the 1959 census, was 1,976,453, of whom 62%, or 1,227,829, were urban. The great majority were Russian (84%), with Ukrainian (11%) and Belorussian minorities. Buryats make up 4.8% and live mostly in the Ust-Ordinski Buryat National Okrug, just west of Lake Baikal. In the north live a few Evenki, while in the Eastern Sayans are a few hundred Tofy. Most of the population is concentrated in a narrow belt along the Trans-Siberian railway, which crosses the southern part of the *oblast,* where are the largest towns, Irkutsk (365,893), Angarsk (134,390) and Cheremkhovo (122,833).

The southern part along the railway and the Angara river is a rapidly developing industrial region, based on the Cheremkhovo coal field and iron ore deposits around Bratsk, together with salt and mica deposits. The large Irkutsk barrage on the Angara supplies hydroelectric power and a huge plant is scheduled for completion in the mid-1960s at Bratsk. Metallurgical and engineering industries have grown rapidly in the main towns. In the northeast, round Bodaibo on the Vitim, gold is obtained in large quantities. Over the rest of the *oblast* timber working is the only important industry, and this is highly developed. Agriculture is largely confined to the neighbourhood of the towns. Reindeer herding and hunting are carried on by the Evenki of the north. (R. A. F.)

IRKUTSK, a town and the administrative centre of Irkutsk *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., stands on the Angara river at its confluence with the Irkut, 66 km. (41 mi.) below the outfall from Lake Baikal. Pop. (1959) 365,893. The town was founded in 1652 by the first Russian colonists of the area and it became the main route centre of Cis-Baikalia. Its importance increased rapidly after the coming of the Trans-Siberian railway in 1898. It became one of the major industrial centres of Siberia, with emphasis on heavy engineering, electrical equipment and machine tools. Other industries include mica processing (from the Slyudyanka mica deposits near the southwestern end of Lake Baikal), timber working, the making of footwear, soapmaking and food processing (meat packing, tea pressing, etc.). Power for its industries derives from the neighbouring Cheremkhovo coal field and from the Irkutsk hydroelectric plant on the Angara, which started operating in 1956. The power station is of unusual design, with the plant built into the barrage itself and no spillways. The reservoir above the dam extends back to Lake Baikal and affords river communication with the lake and the navigable rivers which flow into it. By the 1960s shipping links downstream were possible to Bratsk after the filling of the Bratsk reservoir.

In addition to the Angara river and the Trans-Siberian railway, Irkutsk is joined to Krasnoyarsk and Ulan-Ude by motor roads, running parallel to the railway. Another road runs to Kachuga, at the head of high-water navigation on the Lena. There is also a major airport.

Irkutsk is one of the chief cultural centres of Siberia, although its pre-eminence in this respect has been usurped by Novosibirsk. There is the A. A. Zhdanov State university (1918) and the East Siberian branch of the Siberian division of the U.S.S.R. Academy of Sciences, as well as various scientific research institutions and higher educational establishments. At Listvyanka at the Baikal outfall is a limnological research station of the Academy of Sciences. (R. A. F.)

IRON ranks second in abundance among the metals and fourth in abundance among the elements. The earth's core is largely metallic iron, but in the crust the element has had an opportunity to react with other substances and the free metal is rarely found except in meteorites or disseminated as minute specula in basaltic rocks. Iron is a constituent of hundreds of mineral species; small amounts are found also in water, plants and blood.

Meteors are composed chiefly of iron, and tools and weapons were made from this by primitive man. The Aztecs had implements made of meteoric iron before the coming of the white man, and prized this metal above gold. In general use, however, bronze tools and weapons came long before iron ones, the smelting of copper being an easier process than that of iron. The metallurgy of iron is believed to have been developed in western Asia in the 2nd millennium B.C., spreading in waves that reached other regions at intervals centuries apart.

The Assyrians and Egyptians made considerable use of iron. In Gen. iv, 22, Tubal-cain is mentioned as an instructor of workers in iron and copper; and iron was utilized to make tools and weapons in the time of David. The Dorian invaders, who were the forerunners of the classic Greeks, were equipped with iron tools and weapons. Homer speaks of a ball of iron as the prize awarded to Achilles for athletic prowess. The Greeks obtained ores from the south coast of the Black sea, and the Romans from Spain and Elba; evidently there were earlier sources in India.

Igneous rocks contain an average of 5.01% of iron. The im-

portant ores are the oxides and carbonates from which the metal is obtained by smelting with carbon.

This is done commercially by blowing heated air through a mixture of ore, coke and limestone in a blast furnace under conditions where a maximum temperature of about 1,300° C. is reached. The crude metal obtained is called cast iron or pig iron and contains various impurities; carbon, silicon, sulfur, manganese and phosphorus are most important. Steel and wrought iron are made by oxidizing the impurities in pig iron with air or ferric oxide at high temperatures and collecting them in a suitable flux to obtain the required degree of purification. Commercial production and industrial uses of these materials are treated under IRON AND STEEL INDUSTRY, this article being limited to a general description of the properties of the element and its important compounds.

Iron, as commonly available, nearly always contains small amounts of carbon, which modify its properties. It may be prepared by passing hydrogen over purified iron compounds (the oxides for example) at high temperature or by electrodeposition from solutions of iron salts.

PHYSICAL PROPERTIES

Iron is tetramorphous. The delta form exists above 1,400° C., at which temperature there is a transition to gamma iron. The latter has a face-centred cubic lattice, is weakly paramagnetic and forms solid solutions with iron carbide (Fe_3C); this property is of importance in the preparation of steel. At 895° C. there is a transition to beta iron. This form is body-centred cubic, weakly paramagnetic and stable down to 766° C., where alpha iron is obtained. The body-centred cubic lattice is retained in this transition but alpha iron is strongly paramagnetic, indicating a definite change in electronic structure in going from beta iron to alpha iron. In the alpha form, iron is a soft, ductile, gray-white metal of high tensile strength.

Values for some of the physical properties of the pure metal are given in the accompanying table.

Physical Properties of Iron

Coef. expansion; cubic 0° to 100° C.	0.04355/° C.	Tensile strength annealed wire.	50–60 × 10^3 lb./sq.in.
Electrode potential $Fe=Fe^{2+}+2e$ 25° C.	+0.440 v.	Boiling point	2,735° C.
Ionization potential of gas atom	7.83 v.	Density 20° C.	7.86 g./ml.
Resistivity 20° C.	0.04100 ohm-cm.	Melting point	1,530° C.
		Radius of Fe^{2+}	0.75 A
		Specific heat (average 0° to 100° C.).	0.11 cal./° C.

CHEMICAL PROPERTIES

Iron, the metallic chemical element of atomic number 26, symbol Fe, has an atomic weight of 55.85, which represents a mixture of the isotopes 56, 54, 57 and 58 in that order of abundance. Radioactive isotopes with mass numbers 53, 55 and 59 have been prepared.

Iron is a member of the first transition series, in which the electrons in the third level increase from 8 to 18, and has the following outer electron arrangement: $3d^6$, $4s^2$.

The properties of iron are similar to those of the other transition elements, particularly cobalt and nickel. Iron is also related to ruthenium and osmium, the corresponding elements in the second and third transition series. In common with the other transition elements in this series, it readily loses its 4s electrons to form the +2 oxidation state shown in ferrous iron. The properties of ferrous ion are similar to those of the other +2 ions in the series and it resembles manganous ion, particularly, in the solubilities of its compounds. Ferric iron, the +3 oxidation state, is readily obtained and the ion resembles the chromic ion in the solubilities of many of its salts. The +4 state is realized in perferrite, FeO_3^{2-}, and the +6 state in ferrate, FeO_4^{2-}, both being obtained by the action of strong oxidizing agents in alkaline media. Only a limited number of ferrites and ferrates are known and the most important oxidation states of iron are the +2 and +3.

The Metal.—In accordance with the potential given in the table, metallic iron acts as a strong reducing agent. Solutions containing the ions of gold, platinum, silver, mercury, bismuth and copper are reduced by iron to yield the metal in each case. In contact with nonoxidizing acids, iron dissolves by reducing hydrogen ion to hydrogen gas, forming ferrous ion. Since the metal reduces ferric to ferrous ion, moderately strong oxidizing agents produce ferrous ion if the metal is in excess and ferric if the oxidizing agent is in excess. Iron combines directly with most of the nonmetals at moderate temperatures and may be made to "burn" in many of these cases because of the large amounts of heat evolved in the reactions. Upon immersion in concentrated nitric acid, which does not dissolve it, iron is made "passive" and will not dissolve in dilute acids nor in the metal ion solutions listed above. This phenomenon is shown by other transition metals such as chromium, molybdenum, cobalt and nickel in this series and by many other metals. In general, passivity is produced by the action of strong oxidizing agents, including anodic polarization, and may be destroyed by the action of reducing agents, by scratching the surface, or by specific agents in particular cases. It is apparently caused by the formation of surface oxide films and is useful in controlling corrosion.

Under the usual atmospheric conditions iron rusts to form hydrated ferric oxides. This process occurs in two steps: first, iron dissolves in the acid solution provided by the moisture and the carbon dioxide of the air to form ferrous ion and liberate hydrogen; second, oxygen from the air oxidizes the ferrous ion to form hydrated ferric oxides. The first step is slow with pure iron but is catalyzed by many impurities which facilitate the liberation of hydrogen from the metal surface. (*See* CORROSION AND OXIDATION OF METALS.) Iron reacts with steam to produce hydrogen and ferroferric oxide, or ferrous oxide if the temperature is above about 570° C. Ammonia acts on iron at high temperatures to form hydrogen and the nitride Fe_2N. Carbon dioxide is reduced by the metal at elevated temperatures to carbon monoxide with the formation of ferrous oxide.

Properties of Ferrous and Ferric Ions.—Ferrous ion is pale green in solution and in most of its hydrated salts. Solutions of ferrous ion are only slightly hydrolyzed since ferrous hydroxide is a fairly strong base. The electrode potential of the ferrous, ferric couple is −0.77 v. at 25° C., and solutions of ferrous ion are unstable with respect to air oxidation. Common reagents used to oxidize it to ferric are permanganate, dichromate, peroxide, bromine and nitric acid. Ferrous ion may be precipitated from approximately neutral solution as the sulfide, hydroxide, phosphate, arsenate, carbonate and oxalate; the ferricyanide may be precipitated from acid solution. In strongly acid solution ferric ion is yellow; as the acidity is decreased, hydrolysis occurs to an increasing degree, forming basic ions and colloidally dispersed hydrated ferric oxide, which colour the solution brownish yellow. There is little tendency to form acid ions even in strongly basic media although many compounds contain the +3 state as ferrite, FeO_2^-. Ferric ion is commonly reduced to ferrous by sulfide, sulfite, stannous chloride, zinc amalgam, hydroxylamine and iodide. It may be precipitated from weakly acid solution as the hydroxide, ferrocyanide, phosphate, arsenate, and by the formation of salts with many organic compounds.

In addition to forming simple salts, where the valence and the oxidation number are equal, ferrous and ferric iron form many complex compounds and ions in which the co-ordination number is six; that is, where there are six atoms or groups attached to the metal ion. Simple examples of such complex formation are ferrocyanide $Fe(CN)_6^{4-}$ and ferricyanide $Fe(CN)_6^{3-}$ ions.

The formation of complexes is common to almost all of the ions that have more than eight electrons in their outer shell and is associated with the existence of partially occupied orbitals of closely related energies that can be used to accept electron pairs from various atoms or groups. In the case of ferric and ferrous iron six pairs of electrons can be so shared by using the vacant 3d (two), 4s (one) and 4p (three) orbitals, giving the co-ordination number of six, independent of the oxidation state of the iron. Complexes are formed with iron in which the type of binding of the complexing groups is ionic as well as covalent. Ferric iron forms complex ions with such inorganic groups as water, ammonia, cyanide, fluoride, chloride and thiocyanate and with such organic ions as oxalate, citrate, tartrate, tannate and gallate, to mention

only a few. In addition there are an extremely large number of chelate compounds formed with organic molecules in which each of the organic molecules is bound to the iron through two of its atoms, making use of both valence and co-ordination bonds. Most of these compounds are very stable and are soluble in organic solvents but not soluble in water. Many of the organic reagents such as cupferron, orthophenathroline, 8-hydroxyquinoline and dipyridil, used in analysis for iron, form such chelate compounds; ferric and ferrous hemoglobin, so important in blood, are of this type. *See* Co-ordination Compounds.

COMPOUNDS OF IRON

Oxides, Hydroxides and Acids.—Iron forms three oxides: ferrous oxide, FeO; ferric oxide, Fe_2O_3; and ferroferric oxide, Fe_3O_4. It also forms ferrites, perferrites and ferrates which may be regarded as salts of the potential acids, ferrous, $HFeO_2$; perferrous, H_2FeO_3; and ferric, H_2FeO_4.

Ferrous oxide is a black pyrophoric powder readily soluble in acids. It may be obtained by reducing ferric oxide in hydrogen or by the action of steam, carbon dioxide or oxygen on iron at high temperatures.

Ferrous hydroxide is precipitated from neutral or basic, air-free solutions as a white flocculent material that is rapidly oxidized by air to become green and finally reddish brown as ferric oxide is formed. It readily absorbs carbon dioxide to form ferrous carbonate and is easily dissolved in acids.

Ferric oxide or iron sesquioxide exists in several anhydrous and hydrated forms including the important ores hematite and specular iron, the minerals limonite and goethite and iron rust. It is obtained as a steel-gray powder by igniting almost any ferric compound in air; when finely powdered, the ignited material appears brownish red. After ignition it dissolves extremely slowly in acids, hydrochloric acid in combination with a reducing agent being the best solvent. The finely divided oxide is used as an abrasive called "iron rouge" and as pigment, venetian red.

Ferric hydroxide is not simply characterized since hydrated ferric oxides of various structures and compositions are included by the name. It precipitates as a red-brown gelatinous material that is difficult to filter and tends to form stable colloidal dispersions that are usually positively charged. Among structures that have been characterized by X-ray patterns are alpha Fe_2O_3 hydrate, precipitated as a brown gel by the addition of alkalies to ferric solutions; beta Fe_2O_3 hydrate, formed by the hydrolysis of ferric chloride solutions; and gamma Fe_2O_3 hydrate, obtained under certain conditions when ferrous is oxidized to form ferric hydroxide. The freshly precipitated forms are readily soluble in acids but become more difficult to dissolve if they are partially dehydrated. There is only a slight solubility in strong bases with the formation of ferrite ion, FeO_2^-. Purified colloidal ferric hydroxide is used in medicine as "dialyzed iron."

Ferrites may be prepared by fusing ferric oxide with basic oxides to form such compounds as sodium ferrite, $NaFeO_2$. Magnesium ferrite occurs as the mineral magnoferrite and zinc ferrite occurs as franklinite; iron commonly occurs as ferrite in many complex minerals. The important mineral magnetite is ferrous ferrite, $Fe(FeO_2)_2$.

Ferroferric oxide, mentioned above as ferrous ferrite and magnetite, is always attracted by a magnet and is frequently magnetic; specimens in the latter case are loadstones. The compound is most simply obtained by passing steam over red-hot iron and is commonly observed as mill scale in the fabrication of iron and steel. It dissolves in acids forming ferric and ferrous ions in the ratio of 2 to 1 and a brown hydrated form may be precipitated from such a solution by the addition of alkali.

Perferrites of barium ($BaFeO_3$) and strontium ($SrFeO_3$) have been prepared by heating a mixture of barium hydroxide or strontium hydroxide and ferric oxide in a stream of oxygen. Water decomposes these compounds with the liberation of oxygen.

Ferrates are formed by strong oxidizing agents acting on iron ions in fused alkali or in concentrated alkaline solutions. Thus chlorine acts on a suspension of ferric hydroxide in concentrated potassium hydroxide to form an amethyst or purple-red solution of potassium ferrate. The addition of barium ion to this solution precipitates barium ferrate, $BaFeO_4 \cdot H_2O$, as a dark red powder. Barium ferrate is fairly stable. It dissolves in acetic acid to form a red solution, is not attacked by cold sulfuric acid but evolves chlorine and oxygen from cold hydrochloric acid.

Arsenides, Arsenites, etc.—Several iron arsenides occur as minerals; mispickel or arsenical pyrites, Fe_2AsS_2, is an important commercial source of arsenic. A basic ferric arsenite, $4Fe_2O_3.As_2O_3.5H_2O$, is obtained as a flocculent brown precipitate by adding an arsenite to ferric acetate or by shaking freshly prepared ferric hydrate with a solution of arsenious oxide. The last reaction is the basis of the application of ferric hydrate as an antidote in arsenical poisoning. Normal ferric arsenate, $FeAsO_4.2H_2O$, constitutes the mineral scorodite.

Carbides, Carbonates, Carbonyls, Cyanides.—The importance of the carbide Fe_3C, cementite, in the manufacture of steel is treated under Iron and Steel Industry. (*See* also Carbides.)

Ferrous carbonate, $FeCO_3$, occurs as the mineral siderite or spathic iron ore. It is precipitated from ferrous solutions, by the addition of a soluble carbonate, as a white flocculent material that rapidly oxidizes in air to become green and finally brown as ferric salts form. It is readily soluble in acids. Ferric carbonate cannot be precipitated from solution because of hydrolysis which leads to the formation of ferric hydroxide and basic carbonates.

Carbonyls of iron form an interesting group of compounds. Finely divided iron slowly reacts with carbon monoxide to form ferropentacarbonyl, $Fe(CO)_5$, which distills off at 120° C. It is a pale yellow liquid which freezes at −21° C., boils at 102° C., decomposes above 200° C. and is decomposed by air and moisture. When ferropentacarbonyl is dissolved in a base, the carbonate and the ion $Fe(CO)_4^{2-}$ form, the latter being the anion of the acid carbonyl hydride, $Fe(CO)_4H_2$. Carbonyl hydride is formed when the solution is acidified in the cold. Upon oxidation with hydrogen peroxide, carbonyl hydride yields $Fe_3(CO)_{12}$. In sunlight the pentacarbonyl loses carbon monoxide to form the nonacarbonyl, $Fe_2(CO)_9$, and upon heating the tetracarbonyl, $Fe_3(CO)_{12}$, is obtained. The nitrosocarbonyl, $Fe(CO)_2(NO)_2$, is also known. For the relation of these compounds to the other carbonyls *see* Carbonyls, Metal.

Cyanides.—The very stable complexes ferrocyanide, $Fe(CN)_6^{4-}$, and ferricyanide, $Fe(CN)_6^{3-}$, are formed in excess cyanide and are not decomposed even in strong acid solutions. The ferrocyanide, ferricyanide potential is about −0.4 v., so that the oxidation and reduction of these ions is easily accomplished by many of the common oxidizing and reducing agents. Sodium and potassium ferrocyanides are obtained as by-products in the distillation of coal, after absorbing the evolved hydrogen cyanide in iron oxide "purifiers." Potassium ferrocyanide is commonly called yellow prussiate of potash and the ferricyanide, red prussiate of potash.

Addition of ferric ion to a solution of ferrocyanide first yields soluble prussian blue, $KFeFe(CN)_6$, and then $Fe_4[Fe(CN)_6]_3$, which is the insoluble pigment prussian blue. Many metal ions such as zinc, uranyl and copper form insoluble ferrocyanides of analytical use. Ferrous ion forms a white precipitate, ferrous ferrocyanide. With ferricyanide, ferric ion forms a brown soluble ion and ferrous ion forms Turnbull's blue, $Fe_3[Fe(CN)_6]_2$, which is insoluble. In both ferrocyanide and ferricyanide, one of the cyanide groups can be replaced by other groups such as nitrite oxide, carbon monoxide, sulfite, nitrite or ammonia to form complex pentacyanides. The compound $Na_2FeNO(CN)_5$, sodium ferrinitrosopentacyanide (often called sodium nitroprusside), is used as a test for sulfide in basic solution where an intense blue colour is produced.

Blueprint paper is made by treating paper with ammonium ferricyanide and ferric citrate. Upon exposure to light the ferric ion is reduced by citrate to ferrous which then reacts with the ferricyanide to form insoluble prussian blue. The paper may then be developed by washing out the unchanged ferricyanide and ferric salts with water. (*See* also Hydrocyanic Acid.)

Halides of ferrous ion have the general formulas FeX_2, where X represents any of the halogens. They can be prepared by passing the halogen acid HX over metallic iron or by reaction of excess

metal with the halogen X_2 under controlled conditions. The anhydrous salts are very hygroscopic, form a series of hydrates and, with the exception of the fluoride $FeF_2.8H_2O$, are very soluble in water. The hydrated salts may be prepared by dissolving the metal in aqueous halogen acid solution from which the salts can then be crystallized. The anhydrous salts absorb ammonia to form ammoniates corresponding to their absorption of water to form hydrates.

Ferric iodide does not exist. The other ferric halides, FeX_3, can be made by the action of the halogens on the metal, and the hydrated salts can be crystallized from solutions made by dissolving freshly precipitated ferric hydroxide in aqueous halogen acids. The anhydrous salts are hygroscopic and are quite soluble in water. Ferric ion forms complex ions with the halides and many of the corresponding complex salts are known such as K_3FeF_6, $(NH_4)_3FeCl_6$, etc.

Pharmacopoeial forms of the halides include *syrupus ferri iodide*, a dilute solution of ferrous iodide, and *liquor ferri chloridi*, a strong solution of ferric chloride.

Hydrides of iron do not form as definite compounds but the metal does dissolve hydrogen and some of the other gases to form solutions. The solubility of hydrogen in iron increases from roughly 0.03 vol. of hydrogen per volume of iron at 400° C. to one volume per volume at the melting point. Iron is permeable to hydrogen at high temperatures. Electrolytic iron contains dissolved hydrogen which can be removed in a vacuum. (*See* also HYDRIDES.)

Nitrides, Nitrates, etc.—Several nitrides are known. A. N. Guntz obtained ferrous nitride, Fe_3N_2, and ferric nitride, FeN, as black powders by heating lithium nitride with ferrous potassium chloride and ferric potassium chloride, respectively. G. J. Fowler obtained a nitride, Fe_2N, by treatment of anhydrous ferrous chloride or bromide with ammonia at 460° C.; reaction of ammonia with finely divided reduced iron; or by the reaction of iron amalgam with ammonia at 420° C.; and also, in a compact form, by the action of ammonia on red-hot iron wire. It oxidizes on heating in air and ignites in chlorine; on solution in mineral acids it yields ferrous and ammonium salts, hydrogen being liberated. (*See* NITRIDES.) Ferrous nitrate, $Fe(NO_3)_2.6H_2O$, is a very unstable salt and is obtained by mixing solutions of ferrous sulfate and barium nitrate, filtering and crystallizing in a vacuum over sulfuric acid. Ferric nitrate, $Fe(NO_3)_3$, is obtained by dissolving iron in nitric acid (the cold dilute acid leads to the formation of ferrous and ammonium nitrates) and crystallizing, when cubes of $Fe(NO_3)_3.6H_2O$ or monoclinic $Fe(NO_3)_3.9H_2O$ crystals are obtained. It is used as a mordant.

Ferrous solutions absorb nitric oxide, forming dark green to black solutions which contain the ferronitroso ion, $FeNO^{2+}$. The reaction is utilized in the brown ring test for nitrates. Reddish-brown amorphous powders of the formulas $2FeCl_3.NO$ and $4FeCl_3.NO$ are obtained by passing the gas over anhydrous ferric chloride. By passing the gas into an ethereal solution of the salt, nitrosyl chloride is produced, and on evaporating over sulfuric acid, black needles of $FeCl_2.NO.2H_2O$ are obtained, which at 60° C. form the yellow $FeCl_2.NO$. Complicated compounds discovered by O. Pavel are obtained by the interaction of ferrous sulfate and alkaline nitrates and sulfides. Two classes may be distinguished: (1) the ferrodinitroso salts, *e.g.*, $K[Fe(NO)_2S]$, potassium ferrodinitrososulfide; and (2) the ferroheptanitroso salts, *e.g.*, $K[Fe_4(NO)_7S_3]$, potassium ferroheptanitrososulfide. These salts yield the corresponding acids with sulfuric acid.

Phosphides, Phosphates.—H. le Chatelier and S. Wologdine obtained Fe_3P, Fe_2P, FeP and FeP_2, but failed to prepare five other phosphides previously described. Fe_3P occurs as crystals in the product of fusing iron with phosphorus; it dissolves in strong hydrochloric acid. Fe_2P forms crystalline needles insoluble in acids except aqua regia; it is obtained by fusing copper phosphide with iron. FeP is obtained by passing phosphorus vapour over Fe_2P at a red heat. Fe_2P_3 is prepared by the action of phosphorus iodide vapour on reduced iron. Ferrous phosphate occurs in nature as the mineral vivianite, $Fe_3(PO_4)_2.8H_2O$. It may be obtained artificially as a white precipitate, which rapidly turns blue or green on exposure, by mixing solutions of ferrous sulfate and sodium phosphate. It is employed in medicine. Normal ferric phosphate, $FePO_4.2H_2O$, occurs as the mineral strengite, and is obtained as a yellow-white precipitate by mixing solutions of ferric chloride and sodium phosphate. It is insoluble in dilute acetic acid but dissolves in mineral acids. The acid salts $Fe(H_2PO_4)_3$ and $2FeH_3(PO_4)_2.5H_2O$ have been described. Basic salts have been prepared and several occur in the mineral kingdom; dufrenite is $Fe_2(OH)_3PH_4$. (*See* PHOSPHORIC ACIDS AND PHOSPHATES.)

Sulfur Compounds.—*Ferrous sulfide*, FeS, results from the direct union of its elements. It is best prepared by stirring molten sulfur with a white-hot iron rod; the sulfide drops to the bottom of the crucible. It then forms a yellowish crystalline mass, which readily dissolves in acids with the liberation of hydrogen sulfide "gas." Heated in air it at first partially oxidizes to ferrous sulfate, and at higher temperatures it yields sulfur dioxide and ferric oxide. It is unaltered by ignition in hydrogen. A black finely divided form results when ferrous salts are precipitated by ammonium sulfide.

Ferric sulfide, Fe_2S_3, is obtained by gently heating a mixture of its constituent elements, or by the action of hydrogen sulfide gas on ferric oxide at temperatures below 100° C. It is also prepared by precipitating a ferric salt with ammonium sulfide; unless the alkali be in excess a mixture of ferrous sulfide and sulfur is obtained. Magnetic pyrites or pyrrhotite has a composition varying between $5FeS.Fe_2S_3$ and $6FeS.Fe_2S_3$. It has a somewhat brassy colour and occurs massive or as hexagonal plates; it is attracted by a magnet and is sometimes itself magnetic. The mineral is abundant in Canada, where the presence of about 5% of nickel makes it a valuable ore of this metal. Iron disulfide, FeS_2, is found as the mineral pyrite, which is important as a source of sulfuric acid, and also as the mineral marcasite (*q.v.*); the formula of copper pyrites is $(Cu,Fe)S_2$. Pyrite may be prepared artificially by gently heating ferrous sulfide with sulfur, or as brassy octahedra and cubes by slowly heating an intimate mixture of ferric oxide, sulfur and salammoniac. It is insoluble in dilute acids, but dissolves in nitric acid with separation of sulfur.

Ferrous sulfate, green vitriol or copperas, $FeSO_4.7H_2O$, was known to and used by the alchemists; it is mentioned in the writings of Agricola, and its preparation from iron and sulfuric acid occurs in the *Tractatus chymico-philosophicus* ascribed to Basil Valentine. It occurs in nature as the mineral melanterite, either crystalline or fibrous but usually massive; it appears to have been formed by the oxidation of pyrite or marcasite. It is manufactured by piling pyrites in heaps and exposing them to atmospheric oxidation, the ferrous sulfate thus formed being dissolved in water and the solution run into tanks where any sulfuric acid which may be formed is decomposed by adding scrap iron. By evaporation the green vitriol is obtained as large crystals. Ferrous sulfate forms large green crystals belonging to the monoclinic system; rhombic crystals, isomorphous with zinc sulfate, are obtained by inoculating a solution with a crystal of zinc sulfate, and triclinic crystals of the formula $FeSO_4.5H_2O$ by inoculating with copper sulfate. By evaporating a solution containing free sulfuric acid in a vacuum, the heptahydrated salt first separates, then the penta-, and then a tetrahydrate, $FeSO_4.4H_2O$, isomorphous with manganese sulfate. By gently heating in a vacuum to 140° C., the heptahydrate loses six molecules of water and yields a white powder, which on heating in the absence of air gives the anhydrous salt. The monohydrate also results as a white precipitate when concentrated sulfuric acid is added to a saturated solution of ferrous sulfate. Ferrous sulfate forms double salts with the alkaline sulfates. The most important is ferrous ammonium sulfate, $FeSO_4.(NH_4)_2SO_4.6H_2O$, obtained by dissolving equivalent amounts of the two salts in water and crystallizing. It is very stable and is used in volumetric analysis. It is often called Mohr's salt.

Ferric sulfate, $Fe_2(SO_4)_3$, is obtained by adding nitric acid to a hot solution of ferrous sulfate containing sulfuric acid, colourless crystals being deposited on evaporating the solution. The anhydrous salt is obtained by heating these or by adding strong

sulfuric acid to a solution. It is sparingly soluble in water, and on heating it yields ferric oxide and sulfur dioxide. Many basic ferric sulfates are known, some of which occur as minerals. The iron alums are obtained by crystallizing solutions of equivalent quantities of ferric and an alkaline sulfate. Ferric potassium sulfate, common iron alum, $K_2SO_4.Fe_2(SO_4)_3.24H_2O$, forms bright violet octahedra.

Analytical.—The common qualitative tests for iron are: the formation of Turnbull's blue when a soluble ferricyanide is added to ferrous ion; the formation of prussian blue when ferric ion is precipitated by the addition of a soluble ferrocyanide; the formation of an intense red colour when a soluble thiocyanate is added to ferric ion. In the usual systematic scheme of qualitative analysis iron is precipitated as ferrous sulfide as a member of the ammonium sulfide group of elements.

Quantitative methods for the gravimetric determination of iron include precipitation as ferric hydroxide with ammonia and ignition to ferric oxide, precipitation by cupferron and ignition of the cupferride to ferric oxide. These methods require that the iron be previously separated from a larger number of other metals which would also be precipitated under the conditions required. Accurate volumetric methods for iron involve a reduction to the ferrous state by the use of stannous chloride or zinc amalgam and a titration of the ferrous iron using such oxidizing agents as permanganate, dichromate or ceric ion. A titration of ferric ion with standard titanous solution is sometimes made. Small amounts of iron are determined colorimetrically, and a large number of organic reagents are known which yield intensely coloured compounds; orthopenanthroline, which forms a coloured compound with ferrous iron, is commonly used in the colorimetric determination of small amounts of the element. The thiocyanate reaction is also of use in estimating iron colorimetrically.

Therapeutics.—Although elementary iron comprises only an estimated 0.004% of the average adult body weight, it is an essential element in the body. An intake of 10–20 mg. of iron per day appears to meet the normal metabolic requirements of the average adult. Red meats, egg yolk, carrots, fruits, whole wheat and green vegetables contribute most of the iron in the usual diet. The largest portion (about 55%) of total body iron is found in the red blood cells as an essential constituent of hemoglobin. About 20% of the total is stored in such organs as the liver and spleen, and in bone marrow, to be readily available for conversion to hemoglobin as needed. Except for a small fraction in blood plasma and some iron that is unassociated with hemoglobin in erythrocytes, the remainder is found as muscle hemoglobin, in striated muscle, and as "parenchyma iron" in striated muscle and in almost all other tissue.

Both ferrous and ferric iron form metalloporphyrins in which the iron atom is bound to the four nitrogen atoms in the centre of the flat porphyrin ring. The particular metalloporphyrin obtained from protoporphyrin and ferrous ion is heme, $C_{34}H_{33}N_4O_4$-FeOH. Heme combines with various proteins, presumably by the interaction of the iron atom in the heme with protein nitrogen atoms to establish the maximum co-ordination number of six for the iron. If the protein is globin the resultant molecule is hemoglobin, while other specific proteins give rise to such important enzymes as catalase, cytochrome, peroxidase and Warburg's respiratory enzyme. Hemoglobin, represented as Hb, reacts with oxygen to form oxyhemoglobin, HbO_2, in an amount that is proportional to the pressure of oxygen, until a maximum of about 1.36 c.c. of O_2 gram of Hb has reacted. This is an entirely reversible process and the oxygen taken up to form the equilibrium amount of HbO_2 at some particular pressure of oxygen will be given up by the HbO_2 if the oxygen pressure is reduced to its original value. It is by the use of this property that hemoglobin functions as an oxygen carrier in the body. (*See* also HEMOGLOBIN; PIGMENT, ANIMAL: *Tetrapyrroles.*)

The most important therapeutic use of iron is in the treatment of hypochromic anemias, which are commonly the result of an iron deficiency that impairs the formation of hemoglobin and may impair other functions of the red blood cells. Iron is of little value in the treatment of normochromic and hyperchromic anemias which are not caused by iron deficiency. Any of a large number of iron compounds may be used to supply the element in therapy, and inorganic salts are as effective as organic compounds for the purpose. Among the commonly used preparations are: reduced iron, *United States Pharmacopoeia* (*U.S.P.*); iron and ammonium citrates, *U.S.P.;* ferrous sulfate, *U.S.P.;* ferrous carbonate as Blaud's pills, *U.S.P.,* or as a mass of ferrous carbonate, *U.S.P.;* ferric pyrophosphate, *National Formulary* (*N.F.*); ferrous glutinate and ferrous gluconate.

Soluble ferric salts find a very limited use in the treatment of skin disorders. They are protein precipitants and can produce astringent and irritant effects on the skin and mucous membranes.

IRON AGE. In Greek mythology, the Iron Age was the last of the "ages of man"; archaeologically, too, it was the final technological stage in the Stone-Bronze-Iron Age sequence. The full Iron Age, in which this metal largely replaced bronze in implements and weapons, began roughly about 1200 B.C. in the near east and in southeast Europe. Yet iron had limited use as a scarce and precious metal at least as early as 3000 B.C. There are frequent and widespread examples of the working of iron throughout the third millennium, but it was used in much the same way as copper and bronze. The objects may all have been of meteoric, or celestial, iron. Nowhere is there indication of an appreciation of the qualities of iron which differentiate it from bronze, though man was probably discovering these by experiment as well as by accident. In this early period a distinctive iron metallurgy seems to have developed about 1400 B.C. in Anatolia, and around the Caucasus mountains and the Caspian sea. The export of knowledge of iron metallurgy and of iron objects was rapid and widespread between 1200 and 1000 B.C. Although bronze continued to be used widely, it became the luxury metal while iron was used for mass production. With iron ore much more widespread and more plentiful than copper deposits, the ancient world rapidly converted to iron, even in places where copper or bronze had been used little or not at all. During the early first millennium B.C. important centres of iron metallurgy arose all across Europe. With the large-scale production of iron implements, especially for agriculture, came new patterns of more permanent settlement. Trade increased greatly also, promoting greater cultural uniformity. On the other hand, utilization of iron for weapons put arms in the hands of the masses for the first time and set off a series of large-scale folk movements that did not end for 2,000 years and changed the face of Europe and Asia.

IRON AND STEEL INDUSTRY. Iron is the most useful metal of material civilization; it has made possible plants, tools, machinery and many of the products of the Industrial Revolution. It is principally used when alloyed with other elements, notably carbon; a moderate amount produces steel, an excess produces cast iron. Many special steels for particular uses have been devised that contain a proportion of other metals, such as manganese or chromium (resulting in manganese steel or chromium steel in these two instances). World production in the 1960s was about 250,000,000 net tons of pig iron and 325,000,000 net tons of steel, an increase over the previous decade of about 25,000,000 tons of steel yearly.

The manufacture, uses and properties of iron and steel will be discussed under the following major headings:

I. EARLY HISTORY

1. Antiquity of Iron.—Few implements of iron or steel survive for many years before they rust away; nevertheless there is evidence that the antiquity of iron smelting is great. It doubtless has been discovered and rediscovered many times; explorers reaching primitive peoples in many parts of the world find the native blacksmith using methods very similar to those known to other tribes at far distant times and places. Steelworking and hardening, an advanced stage in the art that doubtless required centuries to reach, was common 3,000 years ago in Greece, and is mentioned in Homer. In the new world, iron occasionally was used in its native state, but smelting was not employed before European contact. (*See* METALLURGY: *History.*)

It is more probable that iron was first found in the ashes of a big fire built near some red paint rock than that the first tools were made from meteorites. When paint rock and fire came to be associated with iron as cause and effect, the next step was to produce it intentionally in fires built against a bank exposed to prevailing winds or in pits or rude rock furnaces where the fires were fanned by bellows, one of the earliest mechanical devices. These are the primitive methods that survive today in the Catalan forge (*see* FURNACE, METALLURGICAL): a mixture of charcoal and iron ore, selected for its purity, is heated intensely for several hours, with fuel additions made from time to time and with a vigorous blast of air fanning the fire. The iron in the ore becomes an incandescent sponge of metal; the clay or other minerals together with the charcoal ash sinter into a slag, permeating the sponge and protecting the reduced iron from further action. After a given time, the furnace is broken into, the glowing ball of iron pulled out and, while white hot, hammered vigorously to expel as much of the slag as possible and to weld the particles of metal into a coherent mass.

2. Steel From Indirect Processes.—With various changes in the furnace details and in methods of producing the air blast, these methods produced all the iron available up to the 14th century. It was truly a wrought iron, the best product containing no more than 0.1% of total impurities alloyed with the metal, but shot through with microscopic slag particles, aggregating 3% or more of the total weight. Steel was made sometimes as an accidental product in the old forges; by design the wrought iron bars would be packed with charcoal in clay boxes or jars and heated for days, whereupon the iron absorbed enough carbon to become steel and thus acquired the superior hardness and strength necessary for keener tools.

As the demand for iron grew, the furnaces became bigger, and a stronger blast of air was required to drive the products of combustion from the bottom up through the mixed charge. As a result, the iron ore was reduced to spongy metal in the upper part of the furnace, and it then proceeded to absorb more carbon as the charge settled down, thereby being converted to pig iron, a much more readily fusible alloy. The bigger, taller furnaces introduced in the early 14th century therefore produced liquid pig iron, a complex alloy of iron, carbon and other elements. Subsequent developments have been along three main lines: (1) increasing the size of the furnace and developing mechanical auxiliaries to produce pig iron more economically and in greater amounts; (2) invention of various processes for changing this impure pig iron into the more useful wrought iron; (3) production of steel either by way of wrought iron or directly from pig iron. Henry (later Sir Henry)

Bessemer's process, announced in 1856, for making steel from pig iron in a pneumatic converter, began the steel epoch. (*See* also CONVERTER STEEL.)

Metallurgical developments consequently have been away from the simple and direct production of wrought iron to the complex, indirect manufacture of steel. The change from the small, intermittent operations controlled by a highly skilled artisan to large, mechanized continuous furnaces has been associated with enormous expansion in total output and a great saving in labour, with a notable conservation of raw materials. The last-mentioned has become a major factor in the free countries of the world. The greatly increased production of the metal in all its forms has caused a shortage of high-quality ores and fuels, which has resulted in important changes in ore processing and in supply routes as well as in extensive studies of means whereby electricity, oil or gas may be substituted for metallurgical coke.

3. Steel From Direct Processes.—Some metallurgists believe that the excessively high temperatures attained in the modern blast furnace cause the pig iron to alloy with undesirable compounds, notably of nitrogen, which cannot be eliminated later, and which, it is believed, causes the metal to be inferior to that produced by the old, direct processes operating at a low temperature. Hence many methods of making iron and steel directly from the ore are proposed periodically, and extended experimentation on a semi-commercial scale has produced some marketable metal by these processes. Most of them rely upon the fact that iron ore is reduced by gas in the upper, cooler part of the blast furnace. That is, the reaction

$$Fe_2O_3 + 3CO \rightarrow 2Fe + 3CO_2$$

is substantially completed at 800° C., or low-red heat, too low to break up other minerals in the ore. Consequently hot iron ore is passed through a revolving kiln containing producer gas, and the iron sponge formed therein is either passed directly to an electric melting furnace or quenched rapidly to prevent reoxidation, separated from unreduced ore and gangue, and the metallic portion briquetted or melted. That these so-called direct steelmaking processes are destined to supplant the indirect system of smelting ore to an impure product and refining the latter is very unlikely. These processes may, however, be able to operate in isolated regions with a good local market where high-purity iron ore is available but good coking coal is not.

II. IRON ORE

Iron is smelted from several oxidized minerals occurring in abundance in the earth's crust. In order of commercial importance, these minerals are hematite (Fe_2O_3), magnetite (Fe_3O_4), limonite (hydrated iron oxide) and the carbonate siderite ($FeCO_3$). Great deposits of these minerals in reasonably pure state, close enough to the surface to be mined easily, occur in many regions. They are so common that an iron and steel industry will be developed whenever and wherever a machinery-using population accumulates. Iron deposits located in sparsely settled countries are potential ores of the future; for commercial uses an ore must be so situated and of such a nature that it can be mined, transported, smelted and marketed at a profit. Proximity to good fuel enhances the value of ore—in Great Britain, inland furnaces smelt local ores containing as low as 23% iron. The enormous ore deposits near Lake Superior in North America are 1,000 miles from coking coal and an iron-consuming population. But intensive production and cheap water transport on the Great Lakes enabled these deposits to dominate the North American market after the turn of the 20th century, shipments averaging 80,000,000 gross tons annually after 1940. The ever increasing needs of the industrial eastern states of the U.S. have been partially met by imports from Venezuela; ore from enormous deposits in Labrador-Ungava and Africa were reaching U.S. furnaces before 1960. The European continent depends largely upon the minette (limonitic) ores of Lorraine—ores that until the beginning of the 20th century were valueless for steelmaking because no way was known to eliminate a high percentage of harmful phosphorus. Sweden, the traditional producer of quality steels, has found it more profitable to export its high-grade ores, and Swedish metallurgists have successfully solved the problem of making a good product from rather poor raw materials.

A. DEPOSITS

1. North American Deposits.—The most productive iron ore region in the world is in very old (Pre-Cambrian) strata surrounding Lake Superior in both the United States and Canada. The Canadian deposits were brought into production in the late 1950s. Several long, narrow areas called ranges contain the workable ores, which are hematites. The names of these important ranges, their locations and the dates of opening are listed in Table I.

TABLE I.—*Important Ranges*

Name	Location	Opened	Name	Location	Opened
Old ranges			Old ranges (cont.)		
Marquette	Michigan	1854	Vermilion	Minnesota	1884
Menominee	Michigan	1872	New ranges		
Gogebic	Michigan and Wisconsin	1884	Mesabi	Minnesota	1892
			Cuyuna	Minoesota	1911

The deposits in the Mesabi range are flat, thick and close to the surface and are, therefore, mined in open cuts by steam shovels. Underground mining is the rule in the others, the veins being fairly steep and worked to 3,000 ft. depth. (For discussion of various mining methods *see* MINING, METAL.)

In view of the tremendous annual production of the iron ranges, it may be questioned how long it will be before the region is worked out. The average iron content of all lake ores dropped from 55½% in 1902 to 51¾% in 1910, and has been maintained since then at a guaranteed 51½% only by mining increasing amounts of high-grade ore and washing, screening or drying one-third of the remainder. Ore shipments were sharply increased at the beginning of World War II and continued at that high level, so that the virtual exhaustion of the open-pit mines could be foreseen in the latter half of the 20th century. Since the Mesabi range is within an iron-bearing formation about 100 mi. long and containing about 70,000,000,000 tons of low-grade material, serious attention was given after 1950 to the concentration of the magnetic iron oxide in this taconite (*q.v.*) rock. By the 1960s several large concentrators were operating and producing high-grade pellets. The method consists of crushing and fine-grinding the taconite, separating the iron oxide (Fe_3O_4) by its magnetism, mixing these magnetite fines with a little binder clay, anthracite dust and water and passing the mixture through a drum something like a long cement mixer. It emerges in spheres about the size of golf balls; these are coated with fine coal and fired at about 1,260° C. into hard, porous pellets that withstand shipping and storage and can readily be smelted in the blast furnace. The taconite contains about 25% iron; the pellets 63%. While the mining and concentration is costly (three tons of rock to one ton of marketable product), this expense may be recovered in lower shipping charges, lower coke and flux requirements and increased rate of production in the blast furnace.

Two-thirds of North American ore comes from the Lake ranges and one-sixth is imported. Most of the balance of about 20,000,000 tons has been taken from many ore occurrences in the Clinton formation in the Appalachian mountains. In the northern Appalachian region the ores are predominantly magnetites and much ore almost free of gangue is produced from them. In the southern part of Alabama, deposits of a low-grade red hematite with an easily fusible gangue are found near extensive coal measures. All these deposits are mined by underground methods; among them are mines that have produced continuously since the earliest iron smelting in North America. Open pit mining of the extensive Quebec-Newfoundland (Labrador) hematite deposits was developed in the 1960s.

2. Lorraine Deposits.—Ore beds second in importance only to those in the Lake Superior region occur in strata of Mesozoic age near the Franco-German border, extending northward into Luxembourg and Belgium. While of recent commercial development, they are the chief ores for the European Coal and Steel Community (France, Belgium, Federal Republic of Germany, Italy, the Netherlands and Luxembourg), which produces 25% of the world's pig iron. Mining is done in three principal basins, Longwy, Briey and

STEPS IN STEEL MAKING

1. View of the upper part of a blast furnace, showing a skip car (lower left) on the inclined track carrying raw materials to the top for charging. These materials—iron ore, coke and limestone—are reduced to molten iron, the first step in the manufacture of steel. The iron is then tapped into waiting ladle cars which carry it to open-hearth furnaces, electric furnaces or Bessemer converters, where it is made into steel
2. A Bessemer converter in full blow. By forcing air through the molten iron, the carbon, manganese, silicon, other elements and impurities are oxidized and eliminated to form steel in about 15 minutes
3. The open-hearth process. The raw materials are charged into a large, shallow furnace hearth. About five hours are required for melting. For about six hours more the heat is allowed to "work" while the refining action takes place, forcing many of the impurities into the slag which forms on top of the molten metal. The picture shows the tapping of a finished heat of steel from the open hearth into a ladle (left). The slag floating on top runs off into the slag pot at the right
4. Pouring (teeming) molten steel from a ladle into ingot moulds
5. The moulds are stripped from the formed ingots, which are then sent to the soaking pits pictured. These furnaces heat the ingots thoroughly and uniformly. The ingots are then ready for the first rolling in the blooming mill
6. First rolling operations of the steel in the blooming mill, where the ingots are reduced and elongated as they pass back and forth through a set of rolls. Up to this point, the steps in making steel are similar, although hundreds of chemical formulae are used to vary its composition, and some variations in procedure are made during various steps according to the destined use of the steel

PROCESSES IN FINISHING STEEL

1. In the manufacture of welded pipe, blooms and billets are first rolled in the blooming mill, then rolled into skelp in the skelp mill. Buttweld pipe is made by drawing the heated skelp through a welding bell, as pictured
2. The Mannesmann process of making seamless pipe. The blooms are heated, then rolled into rounds at the round mill. The rounds are cut to desired length, centred for piercing and heated again to the proper temperature for piercing. Finally the pipe goes to the sizing mill, where it is brought to true diameter by a series of grooved rolls. In the picture, semifinished pipe is emerging from a seamless-tube mill
3. Ingots rolled in the blooming mill are cooled, conditioned and reheated to proper rolling temperature for operations known as descaling, roughing and finishing. In the picture the slab at the right has passed through the last roughing stand and is proceeding to the finishing train. The slab in the left foreground is entering the last roughing stand
4. Examining tin-plated steel. This type of steel is rolled from slabs on the continuous strip mill, wound into coils, placed in a continuous pickler, cold rolled and rewound before it is sent to the tin mill
5. Polishing machine which produces various degrees of brightness on sheets of stainless steel

Nancy in northeastern France. The ore beds occur in flat strata 60- to 120-ft. thick, from 300 to 750 ft. below the surface. The iron is contained in tiny nodules of hematite, cemented with a calcareous or a siliceous gangue. It is only necessary to combine these two to procure a self-fluxing, easy smelting mixture, very desirable commercially even though its iron content is quite low (35% to 42%). Phosphorus is strikingly uniform, being 1.7% to 1.9% of the iron contained, and the Lorraine pig iron must therefore be used in basic steelmaking (see *Bessemer Steel: Thomas-Gilchrist Discovery*, below).

3. Ores in Great Britain.—Since the rich blackband, clay ironstone and brown hematites of the Carboniferous strata have been almost exhausted, 80% of the iron ore mined in Great Britain is taken from leaner strata, averaging only 27½%, which are a continuation of the Lorraine beds. Workable deposits extend in a broad strip from the coast of Yorkshire southwest to that of Dorset and are estimated to contain 3,400,000,000 tons of workable ores. The beds are nearly horizontal, and consequently have broad outcrops in gently rolling ground, thus permitting them to be mined chiefly by quarrying operations. As a rule the individual deposits are small and do not warrant powerful excavating machinery such as installed in the great Mesabi pits. A maximum working face is 30 ft. Such "marlstones" (or simply "stone") contain the iron in tiny oöliths like the Lorraine ore, but near the surface the iron has been oxidized and hydrated to limonite, and at depth it is a carbonate. Gangue materials are either calcareous or siliceous. These deposits have been longest mined in the Cleveland district of North Riding, Yorkshire, and there a limited area has produced 5,500,000 tons a year since 1875. All mining of the carbonate ores is underground, sometimes as deep as 600 ft.; 9- to 12-ft. beds are reckoned excellent. Cleveland ores are suitable for basic steelmaking, wrought iron manufacture or general iron foundry work. Great Britain's ore demands have been slowly growing, annual production of pig iron rising from about 10,500,000 tons after World War II to about 15,000,000 tons by the 1960s—about one-third that of the European Coal and Steel Community.

4. Reserves of Iron Ore.—Conservative estimates by economic geologists indicate that there is enough ore in reserve to last 200 years at the current rate of consumption. Of this huge tonnage, two-thirds is located in the western hemisphere; Brazil and the United States possess most of this, but Canada and Cuba both have notable deposits; France has half the balance, and the rest is scattered about in more or less readily accessible locations. Nothing precise is known about Soviet reserves, but United Nations estimates have been in the range of 11,000,000,000 tons, and the U.S.S.R. has reported substantial reserves and rising production, with increases over a 20-year period from 27,800,000 tons in 1938 to 84,240,000 in 1957, and to more than 100,000,000 in the 1960s. Extensive deposits are reported in China, in the northeastern province of Hopeh and in Manchuria, and good deposits in the lower Yangtze valley. India's largest reserves are in the central provinces, with others in Orissa, Madras and Mysore. Substantial reserves also are known in the Philippine islands and in Indonesia. All such computations assume a certain state of metallurgical art in order to define "ore." But metallurgical art is constantly advancing as shown, *e.g.*, in the notable progress made in concentrating the Minnesota taconites and the use of inferior ores in Sweden. *See* also ORE DEPOSITS.

B. Preparation of Ore for Smelting

1. Transport.—In England and on the continent of Europe much of the iron ore is smelted in furnaces erected nearby—even at the mine mouth. Freight is a minor matter. That which is transported from overseas is handled for the most part in ordinary cargo vessels. In the United States, however, the long haul down the Lakes from the ranges to the furnaces has caused the development of specialized handling equipment. At the mines, hopper-bottom railroad cars of 50 to 60 tons capacity are loaded by steam shovels in the pit or from storage bins at the mine, and hauled to the nearest port. There long lines of ore bins are built out into the water; whole trainloads of ore are dumped in a few minutes by pneumatic devices. When these bins are full, an ore boat docks alongside, the hatches are opened, and a load of 10,000 tons of ore is spouted into the hold in less than a half hour. Ore boats that are used for service on the Great Lakes are of special construction and are essentially long, self-propelled barges with movable decks. When one of these boats arrives at its destination, the hatches are again opened, and enormous grab buckets reach into the hold, scooping out the ore and conveying it inshore and loading it either in railroad cars or on a stockpile. If the furnace plant is inland, trainloads of ore are hauled to the site and dumped in bins or placed in stockpiles. Hopper-bottom cars are used almost exclusively for this purpose, although for stockpiling a car dumper, which turns the car upside down, often is used and the ore is moved to the pile by a grab bucket and overhead bridge. The magnitude and power of this unloading machinery cannot be comprehended unless it has been seen in operation. Large stockpiles, which are almost unknown elsewhere, are the general rule in the United States, where water transportation is entirely suspended by ice during the winter months. Limestone and coke are also stocked in sufficient quantity to provide against irregular deliveries from a distance.

2. Dressing.—Up to the beginning of the 20th century iron ore was seldom treated in any way prior to its utilization. High-grade materials, however, became increasingly scarce, and there was a rapid extension of ore-dressing methods.

Screening is the simplest method. At least one-quarter of the lake ores are improved by this method. In England the miner frequently digs marlstone without removing the loamy overburden; the quarried material is then crushed and the fine particles screened out and discarded. In this way the average iron content of the ore is increased, and the suitability for smelting improved, for too many fines in the charge slow down blast-furnace operations.

Washing is also common in the United States. Many million tons of Mesabi ore are treated in washers. The washer is an inclined trough; from end to end is a stout shaft with plow blades so set on its circumference that, when the shaft revolves, the plows clear the trough bottom and move any solid material gradually along. The fine screenings enter at one end and travel against a copious current of water, which washes out the finer, clay-bearing particles, lean in iron.

Concentration is producing many million tons of excellent pellets for blast furnaces or ore for the open-hearth steel furnaces, as briefly described above in the description of North American ore deposits.

Calcining is common in England, particularly on the Cleveland carbonate ores. The Gjers kiln is ordinarily used, a short cylindrical steel shell set vertically and lined with firebrick. A mixture of ore, with about 5% slack coal, is charged through the top as the burned ore is withdrawn at the base. Such a kiln will drive moisture and carbon dioxide from about 1,000 tons of ore in a week; Cleveland ores lose 27% to 30% in weight, but the resulting ore has had its iron percentage increased to about 31%; still a very lean ore, viewed by North American standards. Lorraine ores contain much moisture, but cannot be calcined because this preliminary heating causes them to powder.

Sintering is a method of converting fine ores or flue dusts into a porous clinker that can easily be smelted. Low-grade North American and Swedish magnetite ores are frequently concentrated by fine grinding and drawing the iron-bearing minerals out of waste rock with strong magnets. This fine magnetite is then moistened and mixed with fine coal and a little flux or with blast-furnace flue dust, and spread over a traveling grate, the coal ignited and burned in a strong downdraft. The resulting clinker smelts so much more easily than the dense magnetic ores that the latter, even of high grade, are frequently sintered at plants in the United States. Sintering of flue dusts recovered from the furnaces and other by-product fines from the steel mills is also done on an ever increasing scale.

C. Blast Furnaces

Having followed thus far the mining, transport and preparation of ore, attention should next be given to the process of smelting

it into metal. This is done in a blast furnace, and the metallic product is a high-carbon alloy of iron called pig iron and containing more or less silicon and manganese. Since a separate article is devoted to the construction and operation of the blast furnace (*q.v.*), these matters will be summarized only briefly here; more attention however will be given to the entire assemblage of auxiliary equipment that together goes to form the blast-furnace department of a modern steelmaking plant. A blast furnace and its top works often rise 250 ft. above ground level. It is round in cross section, bound with steel plates and lined with a thick wall of special firebrick. Piercing the very top of the shell are two side openings leading into brick-lined pipes (downcomers) for venting the furnace gases. The top is closed by a double bell, which in effect is an air-lock for introducing charges of ore, coke and limestone, while preventing the escape of any gas. Charging is continued at such a rate that the furnace shaft is always full. About eight feet above the furnace base is a series of 10 or 12 water-cooled nozzles called tuyères, equally spaced around the circumference, through which hot air is blown into the interior. The coke in the mixed charge burns in this air, producing a region of intense heat sufficient to melt the metallic iron descending to that level from above, and superheat it so much that when it trickles to the hearth it collects at the bottom of the shaft in a pool that remains molten for hours. Five or six times a day this iron is drawn off or cast by opening a taphole at the very bottom.

1. Reduction of Iron Ore.—The chemical reactions that reduce the ore to iron can only be presented here in highly simplified form. At the tuyères the heat is so intense that coke burns to carbon monoxide, thus:

$$2C + O_2 \rightarrow 2CO$$

It is this gas that reduces the ore at a fairly low temperature, *i.e.*, near the top, by a series of reactions that may be simplified as

$$Fe_2O_3 + 3CO \rightarrow 2Fe + 3CO_2$$

The secret of rapid furnace driving to produce big tonnages is to use such ore, or prepared sinter, that the gases may permeate it readily and completely. Pure iron is relatively infusible, having a melting point of 1,539° C.; when alloyed with 4.3% carbon its melting point is about 1,130° C. The freshly reduced iron picks up this necessary carbon to convert it into the more fusible pig iron, either by physical contact with the hot carbon, or, much more readily, by gas reaction

$$2CO \rightarrow [C]_{Fe} + CO_2$$

The principal chemical reactions between ore and gas are such that they are promoted by pressure, and this fact is utilized in some blast furnaces by running them with "pressurized top," as it is called. Even without this device, modern furnaces have been of such size that daily production of 1,250 tons during long campaigns are commonplace. With favourable combination of porous ore, high in iron, and properly sized coke, stone and flux in the charge, production rates reach 1,500 tons per day. Of course in the United States, as elsewhere, furnaces of half that production or less are still economically operating.

The large, tall furnaces cannot operate without first-class coke strong enough to carry the heavy charge column. Such coke is not everywhere available. A notable pilot plant at Ougrée, Belg., has been in operation since 1953 by an International Committee for Research on the Low Shaft Furnace. The furnace hearth is oval, 9 ft. by 3 ft., and the shaft carries 19 ft. of burden. Ore is low grade (26% to 34% iron depending on source) in granules from ¼ to 1¼ in. in diameter, and partially coked coal or non-coking coal is in slightly larger sizes. Air blast is enriched to 28% oxygen and heated to 700° C. Daily production is 40 tons of marketable iron, and campaigns have lasted as long as two months.

Other efforts to make iron commercially without coke ("H-Iron") followed the successful Swedish methods of making sponge iron, in which mixed carbon monoxide and hydrogen gas from an outside gas producer is blown into the lower part of an 80-ft. shaft furnace, withdrawn halfway up and returned to the gas producer for regeneration (except for a fraction passed on up for preheating the top part of the descending column). The lowest part of the shaft is strongly water cooled so the reduced iron is quickly chilled before discharging. Highest quality ore, free from gangue, is desirable; however, about 10% emerges unreduced. Capacity of these furnaces is about 75 tons per day. About 120,000 tons per year is made in Sweden, most of it remelted into high-grade steel.

2. Slag Formation.—Impurities in the ore and the coke ash in a blast furnace must be disposed of. If they contain a preponderance of a single oxide like silica (SiO_2), they cannot even be melted unless sufficient limestone is present to flux them; that is, convert them into an easily fusible glass or lavalike substance called slag (*q.v.*) or cinder. The formation temperature of slag depends upon the relative proportion of basic oxides (lime CaO, or magnesia MgO) and acid oxides (silica SiO_2, or alumina Al_2O_3) that are present in the furnace charge. Like the iron, slag melts in the hot region above the tuyères and trickles down, forming a pool floating on the iron. It is tapped or flushed through a cinder notch located between the tuyère line and the furnace bottom, usually just before the iron is tapped.

3. Ore Handling.—A small size furnace making 600 tons of pig iron a day will consume 1,160 tons of ore, 580 tons of coke, 290 tons of limestone and 2,370 tons of air blast. It produces in addition to the iron 330 tons of slag, 70 tons of dust and 3,400 tons of gas. It requires 17,000 tons of water to keep the furnace parts cool and to wash the dust from the gas. Therefore equipment must be provided to handle expeditiously no less than 26,000 tons of material each 24 hours. Such auxiliaries are so large and so numerous that the furnace itself is frequently inconspicuous, despite its huge bulk. In the United States, much space is ordinarily given to stockpiles. Ore that comes from such storage, or direct from the mine, is dumped into bins alongside the furnace. Other compartments hold coke and flux. On a track underneath operates a scale car, which stops under appropriate gates while the attendant draws off a specified amount. When the proper quantities have been assembled, the car proceeds to the skip pit and drops its load into a car which in turn is hoisted up the inclined bridge and dumped into a hopper at the very top of the furnace.

4. Disposal of Iron and Slag.—The pig iron and slag tapped from a big furnace are led by clay-lined troughs or runners to the edge of the foundation where they flow into ladle cars standing below and are hauled away while still liquid. If the furnace is serving a steelmaking plant, the iron may be taken direct to a steelmaking furnace. More usually it is poured into a mixer that is in effect a storage reservoir, sometimes of 1,500 tons' capacity. A mixer is usually shaped like a huge barrel, made of strong steel plate and lined with firebrick; it may be rolled on its foundation by suitable trunnions so the opening may at one time receive metal from a ladle car above, or later discharge it into another for transfer to the steel furnace. The bad effect on steelmaking processes of sudden variations in composition of the pig iron, so-called off casts, is minimized by dilution in a pool of reserve metal. Furthermore, some of the harmful sulfur may be eliminated from high-manganese pig iron in the mixer if the temperature is properly controlled. Iron that cannot be converted promptly must be cast into pigs, either in a pig casting machine, an endless chain to which is attached a series of molds, or by running iron direct from the taphole into pig molds formed in the sandy floor of the furnace house. Slag may be dumped, or, in some localities, marketed for railway ballast, filling material or concrete aggregate. Since the slag is essentially a calcium aluminium silicate, large tonnages are utilized as raw material in the manufacture of portland cement.

5. Utility of Blast-Furnace Gas.—As noted above, gases from the furnace top are good fuels, but they bear too much dust to be used without cleaning. Much of the coarser ore and coke particles swept out of the furnace with the gas remains in the dust catchers, which are essentially enlargements of the downcomer pipes; the velocity of the gas and its carrying power are reduced in passing through them. Further cleaning, either by scrubbing towers or by electrostatic precipitation, is commonly undertaken. Electrostatic precipitation has the advantage that it handles gas without cooling it and may recover valuable amounts of potash for fertilizer. In this process the slightly humidified gas is passed

through vertical pipes; in the centre of each is a wire charged at high voltage. In the electrical field so formed solid particles drift toward the grounded pipe walls, adhering there until dislodged by hammering.

D. Blast-Furnace Plant

1. Blowing Engines.—The energy contained in the furnace gases is utilized to generate hot blast and auxiliary power for pumping, hoisting and lighting. Cleaned gas is used to drive gas engines connected with compressor cylinders. Compressed air goes to the furnace by way of a stove, therein acquiring a temperature of about 700° C., and on through a brick-lined hot-blast main to a bustle pipe circling the furnace. From the bustle pipe, gooseneck connections deliver blast to the furnace through the tuyère openings. The required amount of air is fixed by the size of the furnace and the pressure, which varies from 12 to 20 lb. per square inch (p.s.i.) with operating conditions (and is correspondingly higher if the furnace is run with pressurized top, as mentioned above), and must be delivered without fail. About 50,000 cu.ft. of air per minute is necessary for a furnace making 600 tons of pig iron per day.

2. Dry Blast.—One auxiliary more commonly installed in Great Britain, although proposed by James Gayley of the United States, reduces the humidity of the blast. Gayley showed that water vapour entering the tuyères, amounting in summer to about 250 gal. per hour, is dissociated into its elements by the white-hot coke, this action absorbing heat not usefully regained within the furnace. Variations in moisture content are especially undesirable, for these produce variations in the temperature at the focus, and consequently change the chemical composition of the pig iron. To produce a low and uniform humidity in the air blast, the compressors may suck air through a refrigeration system. Furnaces in regions with hot, humid summers (as in Birmingham, Ala.) consume noticeably more coke and produce much more pig iron of variable and undesirable chemical composition during the summer, due to large and unpredictable changes in moisture content in the blast. There a variation of the Gayley "dry blast" is used whereby the atmosphere is first drawn through chambers where it is cooled to 4.44° C. by copious sprays of cold water. Air entering the blowing engines is therefore saturated with water at 4.44° C., a constant value, and an absolute amount often but a fraction of the moisture in the original air.

3. Stoves.—Four stoves are usually installed to heat the blast. These are steel cylinders up to 100 ft. high and 22 ft. in diameter. Each has a vertical combustion chamber, either at side or centre; the burned gases then return to the bottom through a multitude of narrow flues made of firebrick (*see* Cowper Stove). In the passage they give much of their heat to the brickwork and flow off through a chimney. In the operation of a four-stove installation, three of the stoves may at any hour be filled with burning gas, thus acquiring heat; the cold blast passes through the other stove; when this one cools off, valves are changed to put it on gas, *i.e.,* heating, and one of the heated stoves on wind, *i.e.,* giving up its heat to the air passing through it en route from engines to furnace. Usually valves are changed every hour. In a four-stove installation, therefore, each stove is heating for three hours and cooling for one.

4. Blast-Furnace Operation.—The blast-furnace superintendent's task is primarily to harmonize operations of various large, mechanical elements. But the furnace itself is his greatest care, even though the principal reactions within it are in mobile equilibrium. Slight variations from normal are self-adjusting; that is, if for some reason a surplus of heat is generated, the action within the furnace changes in the direction that will absorb the extra quantity of heat. Nevertheless the skilled operator is quick to observe clues that indicate deviations from the normal, and he immediately makes such adjustments in the operating conditions as experience tells him will avoid any serious irregularity.

Control of Sulfur.—Sulfur, largely from iron pyrite contained in coke ash, is the most troublesome impurity in pig iron, causing the iron to be very brittle at red heat (red short). High-sulfur castings often crack in the molds after cooling, and high-sulfur steels may break when being worked in rolls or forging. Since no sulfur is removed in the converter or in some open-hearth steelmaking processes, it is essential that the amount of this element in the pig iron be reduced as much as possible. This is done in the blast furnace by charging limestone so the slag will be distinctly basic and thus have a higher solubility for sulfur compounds. Such a slag requires more coke, and some works in the Federal Republic of Germany smelt at low heat and desulfurize the molten iron with sodium carbonate. The harmful effects of sulfur may be mitigated in castings if two or three times as much manganese is present; an innocuous manganese sulfide results. Commercial steels also contain about .75% manganese to neutralize the sulfur as well as to help deoxidize the molten steel (see *Ingots: Gases in Molten Metal,* below). Sulfur may be eliminated in electric-furnace steel by refining at a high temperature under a "carbide" slag very high in lime on which floats some coke. Pig iron for gray iron castings must have less than .10% sulfur; structural steel must contain less than .06%; many alloy steels are specified to contain less than .04% sulfur.

Effect of Silicon on Pig Iron.—A blast furnace working very hot tends to reduce silicon and manganese from any minerals containing them that are present in the charge. Manganese is now considered beneficial in all subsequent processes, but silicon must be sharply limited to pass some specifications. Silicon in pig iron causes much of the carbon present to separate and collect into tiny flakes of graphite, permeating the entire metallic structure; this graphite is responsible for the characteristic gray fracture of castings for machinery; its presence also makes for easy machinability. The carbon would otherwise exist in the alloy as a compound of iron (a carbide, Fe_3C, called cementite) and form a much harder, stronger alloy. Consequently in such things as car wheels or in white iron castings, which are later to be converted into malleable iron by annealing, the silicon must be strictly limited. (Iron malleable as cast requires very low sulfur.) Silicon in pig for steelmaking must also be under close control. Therefore for those irons where both sulfur and silicon are limited, the ore and fuel must be specially selected for a low content of sulfur.

Gray and White Iron.—Carbon is another element in pig iron that will vary somewhat. It may be from 3.0% to 4.25%, depending upon furnace conditions. Generally if either silicon or phosphorus runs unduly high, the carbon will be low. Manganiferous irons, on the other hand, are usually high in carbon. The colour of a freshly broken piece of pig iron is due to the way the carbon is held, rather than its total quantity; in white iron, nearly all the carbon is combined with iron in the carbide cementite; in gray iron, seven-eights of it is in the form of graphite; intermediate proportions are called mottled irons.

Phosphoric Ores and Iron.—Phosphorus, until about the start of the 20th century, was the most undesirable element entering the blast furnace. Whereas much sulfur could be slagged off, between 90% and 100% of the phosphorus entering with the ore and the fuel ash came out with the iron, and an excess made both iron castings and steel brittle. For some types of thin castings requiring fluid iron, *e.g.,* the old-fashioned iron stove plates, from about 1.0% to 1.5% of phosphorus could be permitted, but in steel it had to be kept as low as sulfur, namely, from .02% to .07%; in general, the lower the better the steel. Consequently the phosphoric iron ores of Lorraine were of small value, in fact, of no value for steelmaking, until the Thomas-Gilchrist basic process was announced (1878). Subsequent developments have converted the phosphorus in the ore to a pronounced economic asset; namely, a most valuable fertilizer. *See* also Cast Iron.

III. WROUGHT IRON

Wrought iron, as compared to the total tonnage of steel, is a vanishing commodity. But it should be given some attention for its unique combination of physical properties, which enabled it to survive for 75 years after the Bessemer and the open-hearth steelmaking processes were perfected. It once was the principal metal of engineering construction as well as the raw material from which steel tools were made.

1. Puddling Process.—If about 600 lb. of pig iron and considerable iron ore are placed on the hearth of a small reverberatory

furnace and melted, various reactions occur between the iron oxide from the ore and the impurities in the droplets of pig iron. The first reactions to occur may be simplified as follows:

$$2FeO + Si \rightarrow SiO_2 + 2Fe$$
$$FeO + Mn \rightarrow MnO + Fe$$

The iron thus reduced from the ore enters the pool of metal, and the silicon and manganese oxides join with the surplus ore to form a highly basic slag. This slag has the ability to absorb any phosphorus oxides that result from reactions between the phosphorus alloyed in the metal and the surplus iron oxide in the slag. The workmen stir the slag and iron together, an operation that is known as puddling; after the silicon and manganese have been substantially eliminated from the metal, the carbon content begins to go down. The reaction may be written as follows:

$$[C]_{Fe} + O \rightarrow CO$$

Carbon monoxide gas bubbling upward causes the bath to boil. Removal of all these alloying elements leaves practically pure iron, of a much higher melting point. Toward the end of the process, therefore, the bath is converted into a metallic sponge of white-hot, pasty iron, filled with liquid slag. This is cut into 200-lb. balls by the furnaceman, surplus slag squeezed from the dripping mass and the resulting balls rolled into flat muck bars. The metal is hot enough to weld together satisfactorily, and the process is accompanied by a great spray of slag sparks, squeezed out by the rolls. Muck bars are cut to short lengths, arranged and wired together in piles, heated to a welding heat and rerolled into marketable shapes.

2. Nature of Ferrite.—From a knowledge of the manufacturing process it may be understood that commercial wrought iron is essentially pure iron containing a greater or lesser number of slag particles. By weight, about 3% of the best wrought iron is slag.

A view of a polished section through a microscope shows the structure of wrought iron. The mirrorlike metal appears white in a photograph; the stony lustre of the slag particles appears gray. The slag itself is not a simple glass; it is a high-iron silicate containing more or less manganese and phosphorus and frequently develops well-crystallized minerals. Slight etching of the polished surface develops characteristic markings; the metallic portion seems to consist of a number of closely fitted or interlocking grains. If one of these grains were picked out, it would have an irregular surface; nevertheless it is undoubtedly true that its inner structure is that of a true crystal, that is, the atoms are arranged in regular rows, in geometric order. Such tiny crystals have a body-centred, cubic crystal structure and are called ferrite.

3. Properties of Wrought Iron:—Wrought iron has superior properties for forge welding, because at high temperatures the slag particles melt and spread into a film protecting the metal from atmospheric oxygen. The purity of the iron is responsible for its toughness, or resistance to shock. While no variety of iron or steel can resist rusting (corrosion in moist atmospheres) unless it is alloyed with more than 10% chromium, wrought iron and very low-carbon steel made in open-hearth furnaces and often called "ingot iron" have acquired a considerable reputation for superiority over ordinary carbon steel in sheet forms for siding or culverts. For some purposes a variety known as charcoal iron has been preferred. Wrought iron is only moderately strong in tension, developing from 45,000 to 55,000 p.s.i. ultimate strength. Furthermore it is a soft metal, its Brinell hardness measuring 75 to 80. Likewise the production of big masses of it is tedious, and puddling requires a large amount of exhausting labour from skilled workmen. These facts all combined to hamper competition with the harder and stronger steel, which after the development of the Bessemer process could be made rapidly and almost automatically in great quantity.

4. Cementation Process.—Wrought iron was the material from which steel was manufactured up to the introduction of the processes described immediately below. Bar iron would be packed in charcoal, layer upon layer, in covered stone boxes (fairly tight) and heated for days at about 926.67° C. Many secret mixtures were added to the charcoal but the modern chemist would explain their useful ingredient as some compound like barium carbonate that facilitated or catalyzed the production of carbon monoxide from the hot carbon and entrapped air. This gas reacted with the surface of the steel, and the reaction resulted in carbon being absorbed by the metal, until, after several days, about 0.9% would be present. Toward the end, a bar would be withdrawn and broken and its carbon content and uniformity judged by its fracture. Such a bar of blister steel (so called from its surface appearance) could be forged and hardened into an excellent tool. Frequently, bar steel would be forge welded together and hammered down, the process being repeated several times to increase the uniformity of carbon distribution. Likewise cemented bar could be melted in clay crucibles and poured into steel castings (or into ingots for rolling into steel shapes and bars). This variety was called crucible steel (*q.v.*). The product would be what a modern metallurgist calls "high-carbon steel," a variety still very useful although made by other processes.

IV. CONVERTER STEEL

Prior to 1870 the principal metallic materials of construction were cast iron and wrought iron. The former could be made quite hard, but then was brittle; the latter resisted shock excellently, but was comparatively soft. There was a great and growing demand for metal that was strong, wear resisting and tough, but there was no method of producing it cheaply enough to make, for example, railroad rails. Consequently, an eager market was awaiting the discovery of the Bessemer process for making cheap steel; and in turn the satisfied market created other demands. While accurate statistics are lacking, a reasonable guess would be that 250,000 tons a year of blister steel and crucible steel were being made in Europe in 1865. For the manufacture of fine tools and cutlery such processes survive still. But obviously this very indirect method of getting steel, bit by bit, was totally incapable of supplying the needs of the coming mechanical age. In the United States in the second half of the 20th century, fine steel of "crucible" quality is made exclusively in electric furnaces.

A. Bessemer's Invention

As has been pointed out, most of the alloyed impurities in pig iron can be eliminated by oxidizing them. In all the old refining processes, iron oxide in the form of ore, mill scale or iron silicate slag (basic cinder) is the means whereby the necessary oxygen is carried into the pig iron under purification. While experimenting on some methods for improving metal for cannon in 1856, it occurred to the English inventor Bessemer that this oxygen for refining could be taken directly from the air if a blast were blown on or through the melted pig iron. On trial it not only purified the iron, but, instead of blowing cold and freezing, the metal became hot enough to remain molten even when all the carbon was gone and hitherto infusible pure iron remained. The whole reaction required only a few minutes; at the end an ingot of mild steel could be cast, ready for the forge or rolling mill.

It took years of experimentation before the new process became a commercial success. The conservatism of engineers and construction men retarded the adoption of cheap steel and the installation of the mechanical auxiliaries, largely perfected by the American, Alexander L. Holley, which enabled a plant with two converters to send forth a continuous supply of steel ingots (*see* Converter Steel).

1. Converter House.—Molten pig iron comes from the blast furnaces in ladle cars, and an overhead crane lifts the ladles and pours the contents into the mixer (*see* fig. 1), establishing a reservoir of uniform and promptly available raw material. Uniformity and continuity are foundations of rapid production of Bessemer steel. At the proper time a ladle of iron, 10 to 30 tons depending upon the size of the converter, is poured from the mixer. A small locomotive pushes this full ladle car to the converter house and the contents are run into the hot converter, which is tilted over to receive the charge. The blast of cold air is turned on, the converter tilted up to vertical position and the blow is on.

2. Conversion Process.—The converter itself is a cylindrical steel pot perhaps 10 ft. in diameter by 20 ft. high, lined with a re-

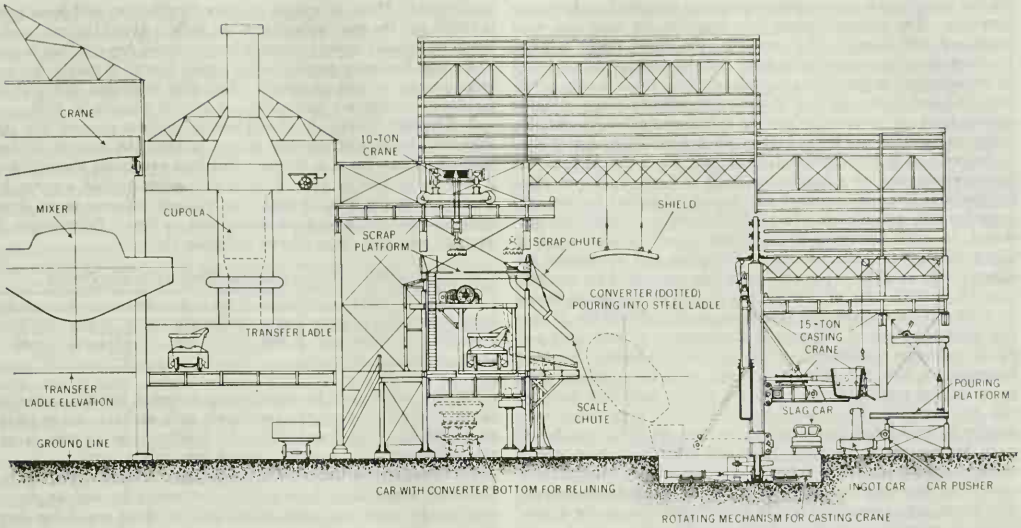

FIG. I.—GENERAL CROSS SECTION OF CONVERTER HOUSE

fractory mixture. The bottom bricks are perforated by many small openings, tuyères, through which air is blown into the metal. Oxygen in the air blast burns the pig iron it first strikes. This product of reaction may be represented by FeO, and it is swiftly distributed throughout the churning mass. At the temperature of operation, silicon and manganese atoms have a greater affinity for oxygen than has iron, so that the following reactions occur:

$$Si + 2FeO \rightarrow 2Fe + SiO_2$$
$$Mn + FeO \rightarrow Fe + MnO$$

These oxides are insoluble in metal and accumulate into droplets of slag—a mixture of iron oxide, manganese oxide and silica. When the metals silicon, manganese and iron combine with oxygen, or burn, much heat is released—enough to heat the incoming air and escaping nitrogen, to provide for radiation losses and to increase the temperature of the remaining metal and slag so it is always quite liquid. During this early stage of the blow the red-hot nitrogen coming from the mouth glows faintly. Gradually the carbon begins to burn, thus:

$$FeO + [C]_{Fe} \rightarrow Fe + CO$$

A roaring boil then takes place in the vessel; the carbon monoxide burns in a big, yellow, luminous flame at the converter mouth, and flying sparks of metal and slag add to the spectacle. In modern plants the course of these reactions is followed by a spectrograph or a photocell that records the presence of incandescent constituents by the colours radiated.

In only a few minutes the carbon is gone; the flame flickers and suddenly contracts. This is the signal for turning the vessel over on its side and stopping the blast. Inside the hot converter is now a seething mass of fluid iron, practically free of silicon, manganese and carbon, covered with a thin layer of slag. The metal, however, contains much gas in solution and if cast immediately would solidify in a spongy mass. Consequently some cupola-melted spiegel (pig iron containing 20% manganese) is run into the converter. A rapid reaction ensues, wherein the steel is freed of oxygen by combination with the excess of manganese and carbon in the spiegel. The converter then tilts further over, discharging its contents into a ladle. The blow has taken perhaps 12 minutes; no greater time is necessary to add the spiegel, pour out the steel, turn the converter upside down to discharge any loose slag chunks and back up to receive another ladle of liquid pig iron. A second converter alongside will be blowing while the first is dumping. The whole equipment of the converter department is coordinated for a complete cycle every 12 to 15 minutes, and is ruggedly constructed, so that delays from breakdowns seldom occur.

3. Converter Lining.—The violent reactions at high temperatures cause considerable scour on the lining of the vessel; especially the tuyère brick at the bottom, which must be replaced after 20 to 25 blows. When a new bottom is required, a car carrying a stout jack is placed under the upright converter, a series of bolts loosened and the jack lowered away, carrying with it the entire bottom part of the shell. This car is immediately replaced by another carrying a new bottom, already warm, ready for lifting and bolting into place. It is therefore unnecessary to leave a shell in the stand while it cools and the lining is repaired, dried and reheated—a matter of several days. In U.S. practice, the lining material is a highly siliceous rock, ground with a little fire clay, moistened and tamped in place with pneumatic rammers. Such a lining is known as an acid lining, and steel made therein is called acid Bessemer steel.

4. Pig Iron Used.—Since the reactions described above leave untouched any sulfur or phosphorus, it is necessary that the pig iron entering the converter be quite low in these two elements. Furthermore, silicon is limited by the rate of driving. It is the chief heat-producing element; if silicon in the pig is high, the converter shell and its contents get superheated during continuous blowings and must be cooled either by dropping a quantity of cold scrap into the shell, by blowing steam in with the blast (which dissociates and absorbs heat) or by delays for radiation. On the other hand, if the converter with a new bottom is a little cold, it is tilted partly over so some blast does not penetrate the iron, but burns the CO to CO_2, thus liberating more heat within the vessel. Maximum production may be had by blowing a pig iron with higher silicon and lower carbon, reducing the blowing time by charging mill scale or ore at the beginning of the blow and charging scrap to absorb the excess heat generated. But in general the pig iron used for acid Bessemer practice, and the product therefrom will be about as shown in Table II.

5. Growth of Uses.—Obviously such material as represented by

TABLE II.—*Average Analyses, Bessemer Converter Process*

Type	Carbon	Silicon	Sulfur	Phosphorus	Manganese
Pig iron	3.5 to 4	1 to 1.25	0.05	0.09	0.5 to 1.75
Full blown	0.03	0.01	0.05	0.10	0.03
With spiegel	0.1 to 0.4	0.10	0.06	0.10	0.90

the last analysis is immeasurably superior to wrought iron for many purposes. The carbon content is responsible for hardness, wear resistance and strength that wrought iron could never acquire. Furthermore, the amount of carbon, and the corresponding degree of improvement in properties, is under control, for it is only necessary to place some charcoal in the steel ladle to make a higher carbon steel, or to use a spiegel or a ferromanganese containing higher manganese and lower carbon when a milder or softer steel is desired. It is not surprising, then, that when the process was finally established on a production basis in Bessemer's own plant in Sheffield, Eng., the product was rapidly absorbed by the railways for rails and wheels. In 1868 there were 110,000 tons produced; in 1888 Bessemer steel reached a peak of production in Great Britain of 1,700,000 tons. Puddling had meanwhile declined; 70% of British pig iron went into wrought iron in 1883; only 5% in 1887. A similar story may be told of the United States. In 1867 460,000 tons of iron rails were made and sold for $83 per ton; that same year 2,550 tons of Bessemer steel rails were produced and some purchasers paid $170 a ton for them. By 1884, however, the last iron rails were made; steel had replaced them to an annual production of 1,500,000 tons a year and the price was $32 per ton. By 1940 rails had declined to a minor commodity in the United States and those were made of open-hearth steel, for reasons to be given later, but much Bessemer steel is made into skelp (flat bars) for welded pipe, and into wire and free-machining steel (low in carbon, but high in sulfur and phosphorus). The Bessemer process has declined in importance in the United States in comparison with the basic open-hearth process because the latter can handle ores with moderately high phosphorus content and can absorb almost any proportion of scrap (even 100% of the charge if scrap is cheaper than molten pig iron). However, the Bessemer process is used to produce the converter steel used in the open-hearth duplex process (see *Open-Hearth Process: Duplex Processes,* below).

B. Thomas-Gilchrist Discovery

1. Control of Phosphorus.—The so-called acid process described above demands low-phosphorus ores and pig, and in Europe such material is relatively scarce and costly. Early efforts to remove phosphorus in the converter failed. Arguing from an analogy in the puddling furnace, where a slag rich in iron oxide carried off phosphorus oxides, it was thought that if the converter blast was carried on after the carbon was gone, much iron oxide would go to the slag, and it would then be in a condition to absorb the phosphorus. When this was tried, however, the iron wasted away, ate into and ruined the lining, but unfortunately had no effect on the phosphorus. Not until 1876 did the Englishmen, Sidney G. Thomas and Percy C. Gilchrist, discover that if the converter were lined with a basic material like burned limestone, dolomite or magnesite, and if burned lime were charged with the pig iron, then a basic slag would form and be maintained in such condition that it would absorb and hold phosphorous oxides produced during the blow. This is the basic Bessemer process widely used on the continent for the production of so-called Thomas steel.

2. Basic Bessemer Process.—A basic plant is arranged much like its counterpart using the acid process. Converter shells are lined with different materials. Dolomite is freshly calcined in a cupola, ground with hot, dehydrated tar and the sticky mass tamped between the shell and a centre form. The perforated bottoms are lined two feet thick, yet must be replaced daily.

In its modern development, a heat of Thomas steel is made by charging 1½ tons of freshly burned lime and then 10 tons of pig iron into a 10-ton converter. The blast is turned on, the converter tipped up and the blow proceeds exactly like an acid heat already described, but it continues after the carbon flame drops. In this last stage the following reaction occurs:

$$5FeO + 2P \rightarrow 5Fe + P_2O_5$$

and the phosphorus joins with excess lime in the slag to form a calcium phosphate. The duration of the afterblow is controlled by chemical analysis; when it is finished the slag is skimmed off as quickly as possible, to prevent the phosphorus from returning to the metal; then the spiegel or other recarburizer and deoxidizer is added and the steel poured into the ladle. About the only additional equipment in the converter house needed beyond that found in an acid Bessemer plant is some handy means of caring for the large volume of slag produced. This slag is ground and sold as fertilizer; it contains up to 20% of soluble phosphoric acid.

3. Thomas Steel.—In this Thomas-Gilchrist process, the pig iron must have relatively low silicon to limit the amount of slag formed. Phosphorus is the principal heat-producing element and it may be as high as 3%. It is doubly essential that a mixer be used to store pig iron, in order that phosphorus may never show wide fluctuations in analysis, from heat to heat. Percentages in average analyses are as shown in Table III.

Table III.—*Average Analyses, Thomas-Gilchrist Process*

Type	Carbon	Silicon	Sulfur	Phosphorus	Manganese
Basic pig	3.5 to 4	0.5 to 1	0.05	2 to 2.5	1 to 1.5
Thomas steel.	0.10 to 0.60	0.20	0.05	0.03 to 0.10	0.30 to 0.50

Thomas steel provides satisfactory material for all classes of tonnage steels used on the continent, such as bars, boiler plate, pipe, structural steel and rails. In England, the process is extensively used for the production of low-carbon steels.

4. Nitrogen Control.—The advantages of basic Bessemer to European steelmakers have been accompanied by serious disadvantages in important applications such as sheet metal for deep drawing. For nearly 50 years this lack of ductility and workability in very low-carbon steel was ascribed to phosphorous; at the end of World War II serious attention was given to nitrogen that would average .015% in Bessemer steel and .005% in more ductile open-hearth steel. Co-operative work by Belgian steelmakers under Pierre Coheur's direction revealed that nitrogen remained low until the carbon dropped to about .50%. If the blow was then continued for two or three minutes with oxygen instead of air, steel of .004% nitrogen resulted, but temperatures would increase so much as to wear the vessel linings excessively. To control temperature, two-to-one oxygen-steam mixtures are used on this late portion of the blow, and low-carbon steels equaling open-hearth in nitrogen and phosphorous content, hardness and drawability are regularly produced. By the early 1960s, practically all Bessemer steel was being made by this process in Belgium and Luxembourg, and the practice was rapidly spreading in West Germany and France. Swedish metallurgists preferred a mixture of oxygen and carbon dioxide for the afterblow.

5. Basic Oxygen Process.—To avoid destruction of the tuyères by a pure oxygen blow, blowing 99.5% oxygen through a pipe (or lance)—the stream impinging on the top of a mixture of molten pig iron and scrap—was tried at the Austrian plants in Linz and Leoben (Donawitz) in 1952. This "L-D process" immediately demonstrated several advantages for the low-phosphorus pig iron from Styrian ores: as much as 35% scrap is used to control temperature; phosphorus, sulfur and carbon are eliminated simultaneously; oxygen efficiency is about 90%; steels very low in nitrogen are produced. On the other hand, gas cleaning equipment must be installed to prevent fumes from becoming a nuisance. The shell of course has no tuyères, is basic-lined and is rebuilt on weekend shutdowns. This process was being used for more than half the Austrian steel production. It is not adaptable to the high-phosphorus pig iron of Lorraine because of the great amounts of slag accumulating between oxygen nozzle and liquid metal, but it has been installed in a growing number of plants in the United States and Canada, where costs of 99.5% pure oxygen in plants capable of making 500 tons of oxygen per day are as low as $5 per ton of oxygen or 50 cents per ton of steel produced.

Another modification of the converter, the Tropenas side-blown converter, is used in many steel foundries. For discussion of this converter and of basic oxygen and oxygen-lance converters *see* Converter Steel: *Converter Design.*

V. OPEN-HEARTH PROCESS

As soon as the Bessemer process attained a production stage, it

was found that the mild steels intermediate in carbon content, strength and ductility between carbon-free wrought iron, on the one hand, and high-carbon crucible steel, on the other, were most useful materials for machinery and engineering structures. These mild steels were really new materials, never before procurable in quantity, and inventors attempted to make them in ways that would not infringe the Bessemer patents. An insuperable difficulty was the inability of any furnace, even when burning high-volatile coal under forced draft, to melt them. As in the puddling process, when the refining reached a certain stage, the metal became a pasty sponge. This obstacle was met by William (later Sir William) Siemens (*q.v.*) who resurrected a forgotten proposal to regenerate some of the waste heat (*see* FURNACE, METALLURGICAL). He passed the fumes from the furnace through brick checkerwork; after the passages had thus been highly heated, air for combustion of the coal was drawn through the chamber. This preheated air had the effect of increasing the flame temperature materially. Using a furnace with such a device, Émile and Pierre Martin made steel at Sireuil, France, in 1864, by melting a good grade of pig iron, adding some selected wrought iron scrap that alloyed with the pig iron and continuing these additions until the carbon content was reduced to the desired percentage, mainly by dilution (the Martin pig and scrap process). Siemens and his brother Friedrich found it necessary to erect an experimental furnace plant in Birmingham, Eng., to develop the application of their ideas in the steel industry. By 1868 the principal features of the open-hearth process were there developed; namely, gaseous fuel, regenerative checkerwork for preheating both air and gas; a thin furnace roof of silica brick; and the method of refining pig iron by adding ore or iron oxide (the Siemens pig and ore process). These furnaces, their hearths, side walls and roofs, were made of highly siliceous refractories; the only slags that would not corrode these furnaces contained an excess of silica—so-called acid slags. Not until Thomas had shown how to remove phosphorus by a basic, high-lime slag in the basic-lined converter did it occur to anyone to make an open-hearth furnace with hearth and side walls of sintered dolomite—lime and magnesia oxide—and to refine the steel under a high-lime slag. J. H. Darby built the first of these basic open-hearth furnaces at Brymbo, Wales, in 1884. The most readily available ores in both England and the United States smelt into pig iron well suited for such basic open-hearth refining; furthermore the product is distinctly superior in quality to Bessemer steel. Consequently the latter is used in the U.S. for the production of low-carbon steels for nonengineering purposes. Basic open-hearth steel, however, makes boiler and ship plate, structural steel, rails and all the higher carbon machine steels (and even alloy steels), such as shafting and forging billets. In the United States, production of acid Bessemer steel is stabilized at about 3,500,000 tons annually; electric-furnace steel (basic) is adding nearly 1,000,000 tons to its production annually, but the large expansion has been in basic open-hearth and basic oxygen steel.

1. Furnace Auxiliaries.—The essential furnace is often dwarfed by the auxiliaries found necessary for rapid and economical production. (*See* fig. 2.)

In the first place, adequate fuel must be provided; if cheap oil or natural gas is not available, another building containing gas producers (*see* GAS INDUSTRY) of the continuous type adjoins the furnace building. The producer house must have adequate coal-handling machinery (a plant with ten 125-ton furnaces would use 800 tons of coal a day) with means for hauling or sluicing the ashes away, and boilers for raising steam to blow into the producers. Gas producers are often found as stand-by equipment, even where other fuels are used, such as mixtures of blast-furnace gas, by-product coke-oven gas, natural gas, tar and oil.

Next a stock of adequate raw material is necessary. If open-hearth and blast furnaces are within the same plant, molten pig iron will be used. That requires a mixer for intermediate storage; otherwise, an ample stock of iron in pigs is required. Furthermore a big tonnage of steel scrap of various kinds is used—the proportions of pig iron and scrap charged into steelmaking furnaces depend solely upon the relative availability and cost of these two materials. Scrap is segregated as to nature and approximate analysis; big shears and drop balls (skull crackers) are used for cutting and breaking unwieldy pieces; traveling cranes and lifting magnets are installed for economical handling of this material. Bins and stockpiles are provided for the various special metals

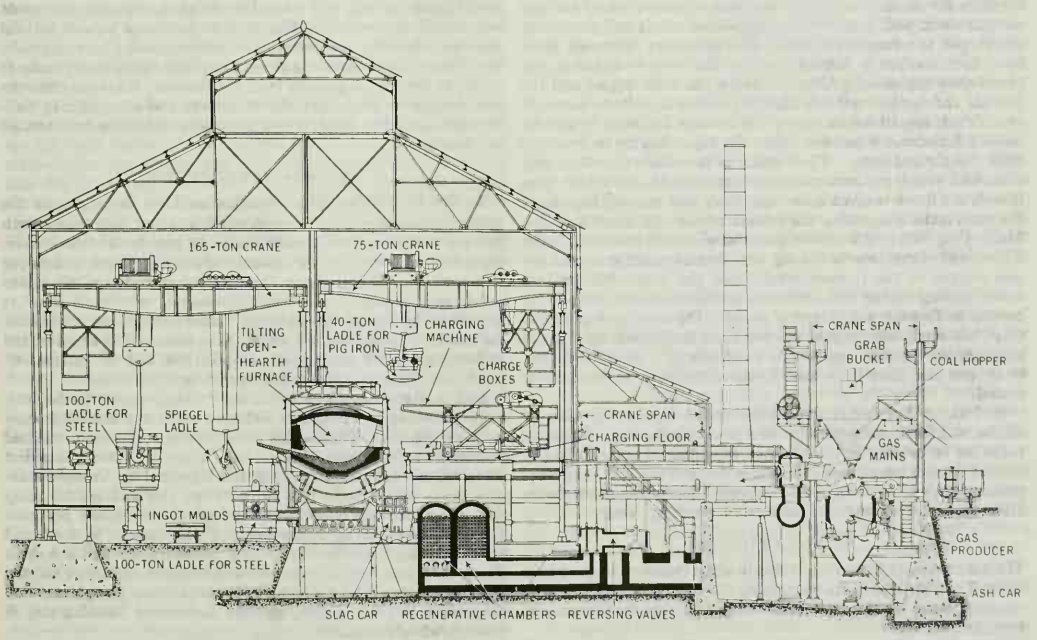

FIG. 2.—GENERAL DIAGRAM OF AN OPEN-HEARTH PLANT SHOWING GAS PRODUCERS AND CRANES FOR HANDLING METAL

used for alloying or deoxidizing the hot steel; for the limestone, fluorspar and other fluxes; for the silica, chrome, magnesite and other firebrick to repair the furnace; and for the dolomite or silica rock used for making the bottoms. In basic open-hearth plants an auxiliary building is necessary for grinding, calcining and storing the dolomite continually needed for repairing the furnace bottom and side walls (banks).

Means must be provided for introducing the fuel into the furnace and reversing the flow of flame at frequent intervals. This requires proper valves in the flues, with an appropriate series of interlocking operating devices. Trends in furnace design call for much shorter and more direct flues than shown in the cross-sectional view and the use of water-cooled gate valves offering no obstruction to gas flow when open. Waste-heat boilers are also quite frequently placed between regenerators and chimney, together with fans to pull the hot gases through them. A device is installed to charge solid material through the doors into the furnace itself. By this means, long delays between heats to refill the furnace are avoided, together with much exhausting labour. All solid materials are loaded into charging boxes, cast steel trays about 24 in. wide and deep and about 4 ft. long, that hold at least a ton of the bulkiest steel scrap. A complete charge for a furnace is assembled into 40 or 50 such boxes, placed on a train of small flatcars and moved to a track running close to the furnace doors. The charging machine operates on a wide gauge track alongside. Its ram engages an end socket on the box and is locked in. The ram then lifts the loaded box off the car, moves it forward through the open door into the furnace and tips it upside down, discharging its contents in the correct place. The empty box is returned to the car and the charging machine moves sideways, taking with it the entire train of loaded cars until the next full box is spotted directly in front of the proper door. This is then picked up, thrust into the furnace and dumped. In this manner a 100-ton furnace can be loaded in less than an hour. Equipment must also be installed to pour the finished steel into ingot molds.

2. Open-Hearth Steel From Cold Metal.—The basic open-hearth process makes most of the world's steel. Many steelmaking furnaces are distant from blast furnaces, so they operate entirely on cold stock, and, as noted, any proportion of pig and scrap may be charged, as economics require. This process as commonly practiced in a stationary furnace and its elementary chemistry are here briefly explained. After a furnace has been tapped and the bottom and banks repaired, charging is begun. Plate scrap, if available, is spread out to protect the bottom, followed by several tons of limestone, depending upon the impurities to be removed from the pig and scrap. The furnace is then filled as full as possible with scrap, pig iron and some iron ore; the doors are then closed, the flame is given an excess of air and melting begins; as the mass melts and settles, the balance of the cold metal is added. Melting pig iron trickles down over the white-hot steel, still solid. Silicon and manganese in the pig iron droplets oxidize by the excess oxygen in the furnace atmosphere and join with the iron oxide forming on the white-hot steel and some of the lime on the bottom or furnace wall, forming a slag. The meltdown period is often hastened, especially if massive scrap is charged, by a jet of pure oxygen directed against the solid charge. Since 1942, jets of oxygen also have been used in the latter part of the refining period.

In four to five hours the molten metal is virtually free of silicon, and much manganese has also gone into the slag. Chemical reactions occur only at the surfaces where metal and slag are in mutual contact, so vigorous stirring is necessary. This is effected principally by gases rising from the limestone, and some two hours after the metal is fluid it continues to break up, thus

$$CaCO_3 \rightarrow CaO + CO_2$$

The gas coming to the surface in big bubbles causes a characteristic boil. The lime also floats up, joining the slag as a base, not only releasing some of the iron oxide contained therein for refining reactions, such as

$$2P + 5FeO \rightarrow P_2O_5 + 5Fe$$

but also maintaining the basic slag necessary to dissolve and hold this phosphorus oxide. When the lime has all floated up, further boiling in the bath is due to the chemical reaction between iron oxide and carbon (which has been going on continually but its effect has been somewhat overshadowed by the lime boil):

$$FeO + [C]_{Fe} \rightarrow Fe + CO$$

The iron oxide is dissolved by the metal from the slag. Bubbles of carbon monoxide gas evolved continue to keep the metal and slag in motion. The active refining reagent in the open-hearth furnace, namely iron oxide, is the same as in the Bessemer and the earlier refining processes, but its origin is different. In the open-hearth process, iron oxide is formed by oxidation of the steel during melting, picked up from the rusty scrap and added as desired to the slag in the form of ore. In three hours the carbon boil should subside, the bath should be low in phosphorus and the slag essentially a high-lime silicate (to hold the phosphorus); the furnace is then driven hard to increase the metal's temperature sufficiently for casting. The slag and the metal have been slowly losing iron oxide and carbon respectively by mutual interaction, and the metal gives up considerable gas held in solution. After 1930 much attention was given to the relationship between the composition and viscosity of the slag existing in the refining stages and the quality of the finished steel. Slag composition is rapidly estimated on the furnace floor by pouring a small "pancake" of slag in a standardized manner and examining its surface, colour and fracture. Its viscosity is measured by the distance the slag flows down a pipestem mold. Likewise carbon in the steel may be closely estimated by rapid magnetic tests; the rate of carbon drop is an indicator of the state of oxidation in the heat. High-grade steels are deoxidized by the controlled slag in the furnace, after which further deoxidizing substances like ferromanganese (an alloy richer in manganese than spiegel, that is, containing more than 20%) or ferrosilicon may be added to the metal bath, followed by various alloying elements, as, for example, chromium, if an alloy steel is to be made. When the word is given, the furnace crew thrusts a long, heavy bar through an opening in the centre door, across the furnace into the bath; several battering-ram thrusts break through the plugged taphole, and white-hot metal rushes down the spout into a ladle set beneath. This ladle is just large enough to hold the steel; slag that follows after overflows into a pit or slag ladle alongside. Certain alloying elements are put in the empty ladle or added to the stream gushing from the furnace: these are elements that oxidize readily, especially aluminum, and are added to well-deoxidized steel to induce a desirable fine grain size in heat-treated machine parts.

A. Variations in Process

1. Use of Molten Pig.—Various methods deviate from the above routine and have been devised to adapt the open-hearth process to the economic conditions to be met by the steelmaker, especially as to the relative amounts of scrap steel and molten pig iron available. These range from processes for handling a preponderance of scrap and a minor amount of molten pig iron (as is usual in the United States) to the Talbot process described below for handling up to 80% hot metal (as is practiced in England and in localities where scrap is not so plentiful, and in "integrated" plants that have both blast and open-hearth furnaces).

In U.S. stationary furnaces of, say, 100 tons capacity, the limestone and scrap are charged as indicated above and heated strongly until well melted. During this time the slag forms from oxidized iron and calcined lime. Within two hours all but the heaviest scrap has melted and molten pig iron is poured in. A rapid reaction starts between the iron oxide in the slag and melted scrap and the carbon, phosphorus and silicon in the molten pig iron. Carbon oxides boiling up through the slag cause it to froth and swell, and much of this "flush slag" flows off through a hole in the back of the furnace well above the molten metal. This slag carries a little sulfur and much of the silicon, phosphorus and manganese in the pig iron, and the amount of finishing slag is correspondingly reduced.

2. Continuous Steelmaking.—Benjamin Talbot first built

furnaces for continuous production of steel at Pencoyd (near Philadelphia), Pa., in 1899. The Talbot process, however, became more popular in England. Furnaces are of large capacity—200 to 300 tons of metal—and are mounted on trunnions; they can be tilted forward and slag skimmed or metal poured through a spout, normally far above the liquid bath. Most of the finishing slag and about 10 tons of steel from the previous heat are retained in the furnace and on this is charged enough burned lime and ore so the first slag can be removed when the metal is .30% carbon above that desired. After heating the slag and furnace for two hours, scrap as available is charged, heated another two hours and about three-quarters of the required molten pig iron is poured in. Reaction is vigorous for about four hours, and then the remainder of the hot metal is added. The bath quickly comes to a good boil and the slag is carefully skimmed off one hour later. This slag carries most of the phosphorus; it may analyze 17% P_2O_5 and is a valuable by-product. The finishing slag is then made up of lime and scale (iron oxide) and the bath worked until carbon, sulfur and phosphorus in the metal are reduced to the required point (about three hours), whereupon ferromanganese is added and the steel is poured into waiting ladles.

3. Duplex Processes.—Other means of speeding the rather deliberate open-hearth reactions are used extensively, perhaps the most important being a combination of acid Bessemer and basic open-hearth. This enables the steelmakers to start with a high-sulfur ore, smelting it to a high-silicon, low-sulfur pig iron, blowing the silicon and carbon out in a converter and transferring the molten steel to a large, tilting furnace where the phosphorus, oxide and gases are eliminated. In U.S. practice, 250-ton tilting furnaces are used; 50 tons of molten steel are reserved in the hearth, a highly basic combination of ore and lime is charged and melted and about 150 tons of blown metal (converter steel) poured in. When the temperature and slag are correctly adjusted, a ladle of basic pig iron from a mixer is charged. A strong carbon boil ensues immediately, and the slag foams up and overflows, carrying much of the phosphorus and some sulfur. When the first reaction slows down, a second ladle of pig iron causes it to resume and drives out the rest of the phosphorus. The slag is then skimmed off, enough pig iron is added to bring the carbon to the desired percentage and the metal finished and superheated for pouring. From such a furnace, 200 tons of steel can be taken every three or four hours.

Duplex processes of the sort described but using two open-hearth furnaces originated in Germany for irons too low in phosphorus for the basic converter. In the first furnace, run at a rather low temperature, the phosphorus and silicon are eliminated into a lime slag rich enough for use as a fertilizer. The furnace is tapped, the slag separated and the metal introduced into another and hotter furnace, wherein awaits a proper slag for rapid carbon elimination. This is called the Bertrand-Thiel process; the Hoesch modification recharges the partly purified metal back into the furnace from which it has just been drained.

4. Acid Steel.—Furnaces made with siliceous bottoms and banks, the descendants of the original open-hearth furnaces, still exist in considerable number. They make steel under slags that are essentially mixtures of iron, manganese and silicon oxides, having well over 50% of the latter, so they are quite acid in nature. Such acid steel has an enviable reputation for quality, but since the furnace reactions remove neither sulfur nor phosphorus, the raw materials and fuel must be selected with much care.

Pig and scrap, as available, are charged cold into the furnace, which has a higher roof to withstand the higher refining temperature; during melting, nine-tenths of the manganese and silicon are oxidized, and join with the rust and burned iron to form a slag. Carbon is eliminated slowly by reaction with the iron oxide in the slag; a little ore is added about two hours after the charge is well melted to keep this reaction going until the residual carbon in the metal equals that required in the steel being made. Temperature is driven higher and higher. Toward the end of this refining period—which may require seven hours—some manganese and silicon re-enter the metal, reduced from the slag by reversible chemical reactions, and are very effective in removing oxygen and other dissolved gases. At the end, the metal is slowly losing carbon but gaining manganese and silicon. However, manganese is still too low for most steel specifications, so an appropriate amount of ferromanganese is added about 20 minutes before tapping. A complete cycle of operations may require up to 16 hours when making steels for ordnance. The superiority of acid open-hearth steel is due to the better grade of raw material used, the small amount of slag formed (perhaps 7% of the metal), the more deliberate working of the heat enabling the furnaceman to bring his metal to the right analysis without making large additions of alloys and the ability to eliminate gases and nonmetallic impurities from a superheated fluid metal while it is still in the furnace. All these procedures tend to produce steel with a minimum of nonmetallic inclusions, a condition found to improve toughness, shock resistance and long life under fluctuating loads (superior fatigue resistance).

VI. ELECTRIC STEEL

Electric furnaces (*see* FURNACE, ELECTRIC) are usually round in plan, with low side walls, flat-domed roofs and invert bottoms, built inside a stout bowl of steel plates, which in turn is attached to some tilting device. The side wall and bottom linings may be either acid—silica brick and fused siliceous material—or basic magnesite. (The acid furnace is confined generally to small installations in foundries and is merely a melting and superheating device, since the unique carbide slags to be described later cannot be formed inside a siliceous lining.) Roofs are of silica brick and are pierced for carbon or graphite electrodes, one for each phase of current, of proper size to carry the electricity without undue resistance. Roofs and electrode operating mechanisms frequently are attached to a pillar so they can be lifted and swung aside, thereby permitting top charging of the entire load from a bucket. Capacities range from $\frac{1}{4}$ ton for small foundries to 50 tons for superrefining liquid steel. Size is limited by the size of electrodes available; a carbon electrode 40 in. in diameter is the maximum; a seven-ton furnace would be about 12 ft. in outer diameter, with 13-in. side walls and the hearth $5\frac{1}{2}$ ft. inside height. In operation, the electrodes are automatically adjusted so the lower ends are constantly a correct distance above the slag. Electric currents of large amperage arc across this gap, flow through the slag to the metal and there neutralize equal currents of opposite phase led in through the other electrodes. Heat is generated principally by the resistance offered by the air gap and the slag layer to the flow of this current. The electrodes are consumed gradually, combining with oxygen of the air within the furnace, producing a carbon monoxide atmosphere, desirable for steel refining. While electrical energy may seem to be an expensive source of heat to melt cold iron, its cost generally has risen less than that of coal, oil or gas. Also, it can be transmitted long distances from its point of generation. Consequently, into the second half of the 20th century, output of electric steel increased more rapidly than its competitors.

1. Advantages of Electric Heat.—No virtue is given to electric steel by the electricity. It is merely a convenient source of heat, under close control. The advantages of electric furnaces for steelmaking are: (1) ability to generate a high temperature and thus cause certain desirable reactions to occur; (2) virtual absence of products of fuel combustion and their unwanted compounds of carbon, hydrogen, sulfur and oxygen; (3) the ability to remove a slag and make up new ones, thus controlling refining reactions; (4) the metal is hotter than the refractory, a prime advantage in cost over crucible melting; (5) there is less slagging of alloying elements, thus making for economy and control of chemical composition within narrow limits. Such advantages are illustrated in the process of superrefining molten metal from the open-hearth furnace; in such operations the basic electric furnace is a unit of a duplex or even a triplex process—the pig iron may be desiliconized in an acid converter, dephosphorized in a basic open-hearth and deoxidized and desulfurized in a basic electric furnace.

2. Superrefining Molten Steel.—Open-hearth steel is taken from the furnace when the carbon has dropped to the required figure, and a little ferrosilicon or aluminum is added to the ladle to

prevent further decarbonization during the transfer. In such condition the phosphorus and silicon are both very low (.010% or less), while the sulfur content depends upon the purity of the metal at the beginning, none being lost in the process so far; in fact the metal picks up a little from the furnace gases. If a nickel steel is to be made, the correct amount of shot nickel is added when the metal is poured into the electric furnace. After the current has played long enough to remelt any crust of metal that may have chilled, a highly basic white slag is made up and melted, consisting mostly of burned lime with only enough silica sand and fluorspar to give it the proper fluidity. In quantity this would amount to about 3% of the metal. An excess of ground carbon is then shoveled in, the furnace closed, left under current for from 1½ to 5 hours, depending upon the quality of steel required, and the doors opened only for sampling or adjusting the slag. Under these conditions of a reducing atmosphere, a high-lime slag and intense heat, calcium carbide is formed by reaction between the lime and crushed carbon:

$$CaO + 3C \rightarrow CaC_2 + CO$$

Slag samples quenched in water give off much acetylene (*q.v.*), easily distinguished by its characteristic odour. Such a carbide slag not only reduces oxygen in the steel but is capable of abstracting the sulfur. The reaction for the latter may be something like this:

$$3MnS + 2CaO + CaC_2 \rightarrow 3Mn + 3CaS + 2CO$$

By this means, ordinary open-hearth charges that usually melt to .05% sulfur are reduced to one-half that amount in a four-hour cycle, while selected charges melting to .015% sulfur can be driven to less than .010% in a heat taking eight hours. It will be observed from this reaction that some manganese is necessary. This will be residual in the open-hearth metal, for it has been found that if 2% manganese is in the original pig iron, the resulting steel, containing .30 to .50 manganese, will be of much better quality, sounder and cleaner, than from a low-manganese charge.

When the soapy slag stops its slight foaming, it is a sign that desulfurizing and deoxidizing are about completed, and the various alloys necessary to make the required analysis are added at intervals in order of their oxidizing power; namely, ferrosilicon first, then ferromanganese, ferrochromium and finally ferrovanadium. Carbon is picked up from the carbide slag and from these alloys. After all these alloys are melted and diffused, the current is shut off and the metal lies quiet for 30 minutes or more, to allow entrapped particles of slag to arise and the superheated metal to cool and liberate dissolved carbon monoxide gas. Slag is then most carefully skimmed, and the steel poured into a ladle that may contain a little carbon, ferrosilicon and ferrozirconium. After 30 minutes further cooling, the metal is teemed into warm, scrupulously clean molds with hot tops. A sectioned ingot will not show any cavities as large as a pinhead.

The above method of desulfurizing and refining steel in electric arc furnaces is not confined to heats starting with molten metal from another furnace, but is far more universally used for cold charges of scrap with or without pig iron.

3. Quality of Deoxidized Steel.—The quality of such deoxidized and desulfurized steels rests in a number of characteristics, some not readily evaluated, such as better response to heat treatment and less nonmetallic inclusions, as shown under the microscope and after deep pickling in strong acid. A better gauge is the transverse properties. If a well-made heat of basic open-hearth steel is forged into a big gun, tension test pieces cut out of this forging will show high ductility if the sample is cut in a direction parallel to the axis of the gun. On the other hand, if these test pieces are cut tangentially to the bore, the ultimate strength is satisfactory but the ductility is not much more than half that of the longitudinal piece. Unfortunately this transverse weakness is in the very direction that must bear the heaviest stress when the gun is fired. An accepted explanation of this phenomenon is that the work of forging ranges the nonmetallic impurities into layers parallel to the faces of compression and interrupts the metallic continuity. Obviously, the cleaner the steel the less would be the transverse weakness. For that reason, important forgings, such as hollow tubes to resist internal pressure, are commonly made of acid open-hearth steel. Even better, however, as shown by typical tests from big gun forgings, is superrefined basic electric steel (*see* Table IV).

TABLE IV.—*Typical Test Results for Selected Physical Properties of Superrefined Basic Electric Steel*

Physical properties	Longitudinal	Tangential
Ultimate strength, p.s.i.	110,000	110,000
Elastic limit	58,000	58,000
Elongation in 2 in., %	24	21
Contraction in area, %	56	42

The excellent tangential properties shown in Table IV are due in considerable measure to the care taken to produce steel low in hydrogen. From the beginning all metal, ferroalloys or slag-forming ingredients are heated to drive off moisture or char any oil or greases. Atmosphere in an electric melting furnace also contains a minimum of hydrogen compounds in comparison with a gas- or oil-fired open-hearth furnace. Any hydrogen from any of these sources that is dissolved by the molten metal is retained (also in solution) in the solidified ingot down to about 400° C., at which point its solubility suddenly drops to near zero. Ingots and forgings are therefore cooled through this range with extreme slowness—days being required for large masses—so the liberated hydrogen gas can diffuse outward and escape from the steel. Otherwise the gas would accumulate as tiny bubbles in favourable spots, such as discontinuities at grain boundaries, and build up internal pressures high enough to start internal bursts known as "snowflakes." Hydrogen gas was also found to be the cause of "shatter cracks" or "internal transverse fissures" in steel rails, so troublesome since the first disastrous wreck from these hidden defects in 1911. In the early 1930s Cameron Mackie of Nova Scotia discovered the following remedy, which is now universally practiced: the finished rails are cooled on the test bed to 500° C. and loaded into insulated railroad cars or cooling pits where it takes them 15 hours to cool to 100° C., thus allowing the insoluble hydrogen sufficient time to diffuse out of the solid steel.

4. Melting Cold Scrap.—By far the larger number of electric arc furnaces in North America are of small capacity for melting cold scrap. It is desirable to start with clean, relatively heavy scrap and melt without additions of iron ore. In a basic furnace, considerable lime would be charged into the empty furnace; melting is done under the heaviest power input practicable supplemented with liberal use of a jet of oxygen to burn the hot iron, producing iron oxide and liberating much heat at the same time. The slag formed on the steel is always black from the rust and the oxide formed during melting. This slag is removed as soon as the charge is melted, and some ground carbon electrode butts are shoveled into the furnace and flapped under the metal. As the carbon dissolves, it first tends to deoxidize the steel

$$[O]_{Fe} + C \rightarrow CO$$

and the carbon monoxide gas comes up in bubbles. Some surplus carbon helps bring the carbon to the required analysis. Then a white or carbide slag is made up, and the refining and alloying are done with current of lower voltage and as described above. An increasing percentage of steel is made in this way in regions where fabrication industries are concentrated. In-process scrap, such as trimmings, punchings and lathe turnings, can easily be remelted, cast into small ingots requiring no heavy blooming mills or forge hammers and sent directly to inexpensive merchant mills for rolling into strip or the smaller shapes required by nearby manufacturers.

5. Induction Furnaces.—The modern substitute for the crucible melting hole is the high-frequency induction furnace. The furnace case is a small cubical box that can be tilted about one upper edge. It contains a cylindrical spiral coil of water-cooled copper tubing that carries alternating current at about 2,500 cycles per second. The coil is electrically and thermally insulated, and a magnesite refractory is rammed inside it to form a crucible, into which is charged selected steel and ferroalloys for simple melting and mixing without refining. The intense alternating magnetic

field set up inside the coil induces eddy or Foucault currents in the metal charge to heat and melt it. Electrodynamic movement of the bath keeps the metal well stirred, which is of advantage in making high alloys of heavy metals, such as high-speed tool steel (*q.v.*), but tends to stir in particles of incidental oxide slag. As a simple melting furnace of rapid action, the induction furnace has no equal for laboratory research.

Electric steel has practically supplanted crucible steel in North America, but has not been so successful in Great Britain. Italy, being rich in water power but very poor in fuel, has several hundred electric furnaces, nearly all of them producing tonnage steels. Small furnaces of this sort are universally used for high alloys cast by the "lost wax" or investment processes (*see* FOUNDING) into such things as turbine blades for gas engines, but the induction furnace was not applied to tonnage production in the United States until the advent of vacuum melting.

Much controversy has turned on the relative quality produced by the crucible and electric furnaces, especially for fine steels and tool steels. It is probably true that there is little difference when selected raw material is charged, an expert furnaceman is employed and equally careful pouring, forging and annealing practice is adhered to; in other words, when equal care is given to the respective heats. But steel from either process can be disappointing when conditions get out of control. The crucible is used only for smaller casts of plain high-carbon steels; the electric is much more convenient for heavy ingots of plain carbon and alloy steels. (*See* also FURNACE, ELECTRIC.)

6. Vacuum Melting.—While magnetic alloys have been melted in moderately high vacuum since 1920, the extension of the practice to commercial steels awaited the perfection of efficient pumps for the very high vacuums required for many operations in the atomic energy industry. First production of vacuum-melted ingots, other than in the laboratory, utilized rather simple equipment—an induction furnace charged with high-grade scrap was placed in a vacuum tank large enough to contain an ingot mold. Appropriate remote controls were provided for observation, temperature measurement, additions of alloys at proper times and pouring the finished steel. Such metal turned out to be unusually free of inclusions and was first made into ball bearings that demonstrated a longer life in service. It also had superior ductility, stress-rupture and creep characteristics, and thus was worthwhile on expensive alloys like tool steels, high-temperature alloys and "super alloys" for gas turbine parts. To minimize the waste time required for pumping down a vacuum tank, semicontinuous units have been placed in operation wherein the charging mechanism and the ingot tank are in auxiliary vacuum chambers so they can be exhausted separately and then connected with the evacuated melting chamber through gate valves. Thus charging, additions and pouring do not interfere with the vacuum in the main chamber even during a week-long campaign. For some alloys a definite program of vacuum, hydrogen reduction and scavenging with argon is practiced during the melting cycle.

7. Consumable Electrode Melting.—The inescapable segregation of impurities toward the centre and top of ingots when solidifying slowly from large masses of liquid has turned attention to an adaptation of the consumable electrode method of ingot manufacture commercialized for reactive metals like titanium. R. K. Hopkins' electric ingot process utilizes a tubular steel electrode packed with appropriate alloys. The arc from its end is submerged in a 4-in. layer of protective slag and gradually builds up an ingot to 12 in. diameter—larger ingots require more than one electrode. Variations in chemistry are surprisingly small; directional properties of pancake forgings made from cross-sectioned ingots are uniform, showing no lack of ductility at the center.

VII. INGOTS

1. Gases in Liquid Metal.—Early attempts to make steel in England by the Bessemer process were failures because the metal boiled over when poured into ingot molds, and the remaining portion when solid was full of blowholes, like a Swiss cheese. Robert Mushet noted that the only apparent difference between sound ingots and the spongy ones was that the former were made of high-manganese pig iron and a little manganese remained in the steel; consequently he proposed adding some of the metal after the blow. Thus originated the practice already mentioned of adding spiegel or ferromanganese to heats of steel made by any of the Bessemer or open-hearth modifications. The purpose of the addition is to remove oxygen from the molten steel. In the crucible and acid open-hearth process much of this oxygen is eliminated by holding the melted metal quietly in the furnace until reactions between the siliceous linings and the metal allow the latter to absorb some silicon which, in turn, is very effective in removing dissolved or combined oxygen existing in the steel. This time-consuming reaction is avoided when producing cheaper steels in great tonnages by adding the deoxidizers to the steel in the ladle, or even as it is poured into the ingot. Melted spiegel is used for medium-carbon Bessemer steels. Since spiegel ordinarily contains 20% manganese and 5% carbon, sufficient manganese to quiet the steel will also introduce considerable carbon. Should this be too much for the desired grade of steel, ferromanganese is used instead. Since a relatively small amount of this is required, small pieces are placed in the ladle and melted by the inrushing steel; if the metal still seems too effervescent on casting, a few aluminium shot are thrown into each ingot. The principal effect of each of these additions is to convert harmful iron oxide in the steel to MnO, SiO_2 or Al_2O_3. These oxides are highly insoluble in metal and tend to accumulate into slag particles and float; but there is little opportunity for elimination when the reactions occur in the ladle or ingot mold. Entrapment of microscopic inclusions is an unmitigated evil for high-quality steel or alloys for severe services. An industrial exception would be the high-sulfur steels, intentionally loaded with manganese sulfide particles, which form the so-called free-machinable varieties; the sulfides embrittle the chips so they break freely away from the lathe tool or milling cutter. Lead is also added to steels for improving machinability—the tiny lead particles act as lubricants. A few hundredths of a per cent of aluminum added to a well-deoxidized or "killed" steel will cause it to retain a fine grain size after working and heat-treating, and this is desirable for most engineering applications except for machine parts that must steadily resist high stress and high temperature. Such "creep resistance" is usually enhanced somewhat by a coarse-grained microstructure.

2. Teeming Practice.—It is usual practice to transfer steel from a converter or open-hearth to the ladle while it is somewhat too hot to pour; also to use a ladle of correct size so most of the slag overflows. Ladles, therefore, contain from 5 to 200 tons of steel, depending on the furnace served. They are strong steel pots lined with firebrick and equipped with trunnions and shackles for crane transport (*see* fig. 3). Very hot metal is kept in the ladle sometimes as long as half an hour, to enable the trapped slag particles to float to the top. Then the ladle is carried to the ingot molds and the metal teemed through a hole in the bottom. When one mold is filled, the metal stream is stopped until the ladle is moved to an empty mold. Splashing against the inner sides of the molds must be avoided, for such splashing is the most general cause of surface defects on the finished articles. As shown in fig. 3, the molds are open-ended iron castings, usually with the larger end at the bottom for ease in stripping off the mold, and are placed on "stools" of cast iron or copper. They are usually coated inside with tarry smoke.

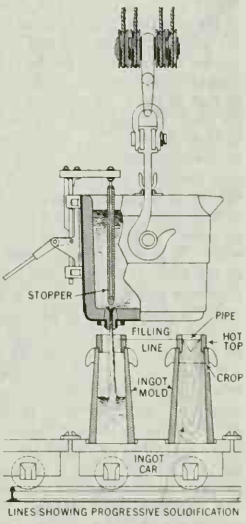

FIG. 3.—LADLE CONSTRUCTION AND METHOD OF POURING INGOTS

Steel castings are ordinarily teemed in the same way; electric or open-hearth furnaces in steel foundries are usually very small compared with furnaces serving rolling mills. Ninety-seven per cent of all the steel made is cast into ingots.

3. Cavities in Ingots.—Deoxidized or "killed" steel contracts in volume when it changes from liquid to solid; consequently the solidified ingot will have a cavity, or pipe, in that part that solidified last. Good practice so proportions the chilling effect of the mold, the temperature of the steel and the rate of pouring that the ingot solidifies from the bottom up.

A hot top in the form of a firebrick collar set on top of the mold, as shown in fig. 3, is a useful device for keeping the top portion of the metal fluid until the last and in condition to feed and fill the shrinkage cavity below. A certain segregation or concentration of alloying elements also occurs toward the pipe; consequently all the defective top must be cropped as indicated and remelted as scrap. Segregation and piping is also minimized by casting ingots big end up and by slow pouring of rather cool metal. The latter is well accomplished by having several ingot molds on one stool, teeming into a central runner and allowing metal to rise in the molds through connecting passages in the common base. Very large ingots for heaviest forgings such as electrical generator rotors and marine shafting may weigh 100 tons or more. In such sizes, the metal at the very centre solidifies at such a slow rate that the effect of shrinkage and solidification cannot be avoided. Practice then is to bore a large hole axially through the ingot or rough forging, thus removing all the defective metal, then searching the interior bore visually or by magnetic powders for traces of unremoved cracks and testing the body of the remaining metal by ultrasonic waves to discover any deep-seated discontinuities.

Enough gas is left in most low-carbon tonnage steels so a slight effervescence occurs in the mold, just enough to counteract the piping tendency. When properly made and cast, such ingots will have a flat top, a smooth solid surface, but a number of deep-seated, small blowholes. During subsequent rolling, these are squeezed shut and the metal welds together more or less effectively. In contrast with fully deoxidized, "killed" steel, metal of this sort is called "rimming" steel; the dense surface of the metallic ingot is an ideal start for thin sheet, small wire or nails.

4. Stripping and Soaking.—Size of ingots depends upon the use to which the metal is to be put. Ingots of alloy steel and high-grade tool steel sometimes weigh no more than 100 lb. Forging ingots are from two to five times the thickness of the biggest part of the resulting forging; those for rails, plates and structural shapes are adjusted to the size and capacity of rolling mill and the cross section of the desired product; for rolling mills, they are generally square in cross section, with rounded corners and about three times as high as thick. A common size is $2 \times 2 \times 6$ ft., weighing about six tons. Forging ingots are frequently fluted hexagons or octagons in cross section. The molds are heavy-walled iron castings, made of low-phosphorus, low-sulfur pig iron, such as is suitable for the acid Bessemer process, smoked or sprayed with lime wash. When the metal in the ingot has solidified, the train of molds is moved to a stripper, an overhead crane with a vertical plunger that can be forced down on top of the ingot, holding it down against the stool. A pair of stirrups then loop over the ears on either side of the mold and lift; if the inner surface of the mold is in good condition and smooth, there is no difficulty in removing the mold, and it is then placed on an empty car alongside. At this time, the surface of the ingot is at a full red heat, yet the interior may still be white hot. To equalize the temperature, the ingot is placed in a soaking pit, a square firebrick chamber large enough to contain two to six ingots standing on end; an arched cover rolls aside for entrance. Auxiliary heat is supplied as necessary by a gas-air flame, operating through regenerative checkerwork, ports and auxiliary control as described for open-hearth furnaces. Pit capacity for at least 100 ingots is required to maintain a steady supply of properly heated metal to a modern rolling mill.

5. Continuous Casting.—Ingot molds filled from the top are almost the exclusive means of providing solid metal for the rolling mills. However, the aluminum and copper industries demonstrated the advantages of continuous casting in producing slabs or rounds of any desired length with minimum segregation edge to centre and zero segregation end to end. In 1953 equipment of this sort was placed in operation at Beaver Falls, Pa., producing rounds of alloy steel capable of being pierced into seamless tubing without preliminary "breakdown" in a rolling mill or forge. A much larger casting machine was started in 1954 in Welland, Ont., casting slabs of stainless steel 5½ by 21 in. in cross section. The mold is a water-cooled copper collar, 20 in. high, open at both ends. At the start of a cast, the bottom is closed by a dummy ingot. As steel is slowly poured into the collar, the supporting metal is as slowly withdrawn downward by pinch rolls and drenched with water sprays. Slabs of appropriate length are cut from the bottom and sent to the reheating furnace prior to rolling into sheet.

VIII. ROLLING MILLS

1. Hot-Working.—A spongy lump of wrought iron, hot from the furnace, requires forging in order to squeeze out much of the trapped slag and to consolidate the metal. Even the best ingot of steel is improved by hot work, such as forging or pressing; its fracture is changed from a coarse crystalline cleavage to a fibrous appearance associated with greatly increased toughness; it also becomes more amenable to heat-treatment. Formerly all this was done on the blacksmith's anvil. Massive gun tubes and armour plates are forged slowly in hydraulic presses; heavy engine parts, axles and cranks are beaten out by steam hammers; tools, levers and machine parts are forged under drop hammers. In every instance the aim is to convert a steel casting (ingot) into a special shape with improved physical properties.

Modern machines and structures require large quantities of steel parts of uniform cross section, such as plates, bars, beams, rails, pipes, sheets, etc. These are made in rolling mills where the work is performed by passing the red-hot metal through one pair of heavy rollers after another, so grooved and spaced that each succeeding pass is smaller and more nearly the required final shape. While the products of a rolling mill vary widely in weight and shape, a common characteristic is that each piece is of uniform cross section from end to end and is of a length limited only by the size of the original ingot, or by the size of the runout floor.

The word "mill" may mean the entire steelmaking plant, just one department or one stand of rolls in the department. Complete departments have various names, such as rail mills, structural mills, plate mills or merchant bar mills, depending upon the product they most efficiently produce. Each such mill contains a number of roll stands of decreasing size and power, from the blooming or cogging mills that do the heaviest work, down through the intermediate stands to the last pass, finishing mill or finishing stand, which impresses the exact final cross section. Nearly all of this work is done at full red heat, at which the steel is quite plastic. Some products, such as shafting, sheet and wire, are finished cold, either for a much smoother surface or for enhanced strength from cold-working in passing through the planishing mills or the wire dies.

There still exist many rolling mills, some producing the highest type of tool steel, that start with a small piece of metal (a 150-lb. ingot or a chunky rolled bar called a billet) and produce rods, bars, hoops or flats a fraction of an inch thick. Metal is passed back and forth by tongs in the hands of skilled labourers. Such roll stands are usually arranged side by side and the hot bars are looped from stand to stand, entering from alternate sides, until the final shape is produced. Sometimes curved guides are installed to do the work of alternate workmen; as the size of the bars increases, hand labour cannot cope with the situation. Most rolled shapes start from white-hot ingots, perhaps six tons in weight, which are taken from soaking pits by a traveling crane and placed on the first of a series of "tables"—power-driven roller conveyors—that transport the metal wherever a distant electric-switch operator directs.

Blooming mills are usually arranged so the ingot is passed back and forth several times through the same roll stand. This requires a screw-down device and indicating dial on top of the housing for lowering and reversing the rolls progressively as the piece becomes smaller. The spindles connecting the rolls to the driving engine

or motor are of most rugged construction, for upward of 20,000 h.p. is transmitted at times. Obviously the whole mill—tables and rolls—reverses rotation for successive passes; hence the name "reversing, two-high mills." Other heavy mills have three rollers ("three-high") and are not reversing; the tables at either side of such a stand are tilting or elevating, so the billet or slab passes forward between bottom and intermediate roll and backward between intermediate and top roll. Four-high mills are mostly used for strip and continuous sheets and plates.

2. Heating Furnaces.—In a modern rail mill the ingot, having been reduced to a long bloom perhaps eight inches square in cross section, has its ends sheared off to sound, unpiped metal by massive guillotine shears operated by hydraulic power and is cut into such lengths, called billets, that each billet will make one or two rails of required length and cross section; these are then reheated before further rolling; other mills that reheat cold billets require special furnaces, usually gas- or oil-fired, frequently having waste heat boilers or recuperators. Furnaces have a long, rectangular hearth, slightly inclined, as wide as the billet is long, and a low roof. Water-cooled skids carry the weight of the steel and prevent scraping on the brick furnace bottom. At the cool end, billets are pushed in sideways by a plunger, one by one, moving ahead closer to the hot end. Every time a cold piece enters the furnace, a hot one is pushed out the other end on a roller table leading to a roll stand; other continuous furnaces have water-cooled rollers or other devices built into the bottoms for moving lighter pieces, such as wire coils, through them at a slow, steady rate.

Small electric-furnace plants casting small ingots frequently heat them by high-frequency currents using the same principles as described above for induction furnaces. In this instance, the cold pieces are pushed end to end through closely fitting brick channels around which the conductors for the alternating currents are wrapped spirally. Frequency of the current, spacing of the spiral and timing of travel is so adjusted that the ingot or billet emerges at correct heat for rolling.

3. Rail Manufacture.—A reheated bloom in a rail mill may then be given four more passes in another reversing mill, called the first roughing stand, passing then to the first finishing stand. This is three-high, *i.e.*, there are three rolls in a stand. The forward pass is through a groove cut in the lower and the middle roll; the receiving table is then elevated bodily and a backward pass is made between a groove cut in the middle and upper roll. Four such passes and a final one through a finishing stand complete the rail; a total of 15 passes and one reheating will convert an ingot into a rail weighing 100 lb. per yard. Structural shapes such as angles, channels and I-beams are rolled in a similar routine. Frequently rail mills, by simple change in rolls, are made to produce structural steel when there is no market for rails. Special and extra-heavy equipment is necessary to roll the massive H-beams with deep flanges used for building columns.

More intricate shapes in both carbon and alloy steels are made by extrusion, a process long utilized for softer metals in the nonferrous industry. Adoption of this process awaited the discovery of some lubricant that could keep the hot metal from scoring the exit die. Molten glass was proposed by French metallurgist J. Séjournet; in fact, the extrusion billet can be heated in a bath of molten glass. Enough adheres to the surface when the billet is transferred into the cylinder of the extrusion press so a thin film always sheathes the hot metal, no matter how high the pressure exerted by ram, cylinder, die or piercing tool. Irregular and hollow shapes can thus be made very economically; one appropriate die takes the place of a whole set of intricate rolls. (*See* also DIE CASTING [PRESSURE CASTING].)

4. Plate Manufacture.—These departments are less complicated than a rail mill, although the machinery may be more rugged. First the ingot—6 to 10 tons and up to 30 tons or more—is rolled to a flat slab in a blooming mill, sheared into pieces and the slabs reheated. Further work is done by cylindrical (ungrooved) rolls. A single reversing two-high roll stand may do all the work, or two three-high mills with elevating tables may be used. Because of the enormous bending stresses carried by the rolls when rolling wide plates, many two-high reversing stands have been built as four-high mills, having two rather small working rolls, each backed up with a larger one for stiffness. Plates of more uniform thickness, edge to centre, may be made in this way. The action of a rolling mill does not widen the piece very much—most of the change in shape results in increasing its length. Consequently a heavy slab is cut to a length that equals the width of the required plate, and it enters the plate rolls sideways. Cross-rolling in this way results in a better plate; metal worked in only one direction acquires transverse weakness. This means that the ductility of bars cut with their axes parallel with the direction of extension during rolling will be higher than when cut from the plate with axis in any other direction. Other mechanical devices employed in a plate mill include plate straighteners, cooling beds, crosscut and edge shears, turnover devices, caster beds and magnetic grips. Side shearing on narrow plates may be avoided by using a universal mill, which is a roll stand to which is added a pair of stout vertical rolls. The latter are adjustable, up to perhaps 48 in. apart, and are set a proper distance to keep the hot plastic plate the exact width during its formation.

IX. MILLS FOR SEMIFINISHED MATERIALS

1. Continuous Mills.—Four classes of semifinished materials are manufactured in such tonnage that special mills are set up to produce them, namely: sheet bars, skelp, strip and continuous sheet (wide strip) and wire rods. These products are the raw material for special manufacturing plants often located at a distance from the steel furnaces. Sheet bars are worked into tin plate, galvanized and uncoated sheet; skelp is made into pipe; strip is narrow sheet for hoops and bands; continuous sheet up to 96-in. wide is shipped in coils to manufacturers of automobile bodies, refrigerator cases and smaller stampings; and rods are drawn into wire, from which all kinds of fencing, screening, cable, nails and springs are made. Sheet bars and skelp are made in bar mills, frequently located immediately beyond a blooming mill, which take a six-inch square bloom hot from the shear and roll it into the thin narrow plate without reheating. Such a plan requires the most rapid handling to complete the rolling before too much heat is radiated. This is done by placing a succession of two-high roll stands in tandem, within a few feet of each other, and guiding the bar automatically from one roll to the next. Since each pass elongates the piece, the speed of each roll is higher than the preceding, and the relation between speed and reduction must be nicely adjusted so the hot bar will neither buckle nor be stretched at any stage. A succession of eight or ten such rolls, with perhaps three pairs of vertical rolls to control the width—interspersed in the train—can produce standard width 8-in. sheet bars or skelp from 6 to 20 in. wide (suitable for forming into pipe up to 6 in. in diameter) and from $\frac{1}{4}$ to $\frac{3}{8}$ in. thick, at the rate of 4,000 to 20,000 tons per week depending upon the sectional area of the bars manufactured. Since a mill of this sort can easily produce material far too long to ship, flying shears are set beyond the finishing roll to cut the rapidly moving bars squarely to length. Sheet bars are sometimes quenched by traveling down a long table under a series of water spray nozzles.

2. Sheet Mills.—Sheets are $\frac{1}{8}$ in. thick or less, whereas plates have sufficient mass to retain heat until rolled to proper gauge, and a surface covered with mill scale is quite good enough for most purposes. Sheets, because of their thinness and the excellent surface demanded by such finishing operations as galvanizing or lacquering, must be rolled in an entirely different manner. Hand methods of rolling sheets originated in Wales in the 18th century.

In hand-rolling, sheet bars are cut with length slightly greater than the width of the required sheet, heated to a dull red (850° C.) and rolled sideways through a two-high mill with massive cylindrical rolls, 32 in. in diameter. One workman catches the bars as they come through and passes them back to another over the top roll; a third screws down the top roll gradually to continue the reduction. The crew passes two bars back and forth very dextrously; when these bars have been flattened to about $\frac{3}{32}$ in., one is placed on top of the other, the top roll raised and the pair rolled down until it is about twice as thick as the desired sheet. In the best practice, one pass is then given in the mill to be used for finishing, in order to "shape" the pack to this mill.

By this time, reheating is necessary; the pair is opened, that is, the two sheets are separated and placed in a furnace until the temperature is up to about 800° C. Low temperatures and a smoky flame are necessary to prevent surface oxidation in the furnace. A pair of these sheets is then further rolled to the required thickness in a finishing mill, more accurate in construction and requiring more skill to operate. For thin gauges, sheets are folded double and rolled in packs of four or even eight. Frequent opening and reheating is necessary in the latter stages of the process. They are then straightened and sheared to size.

Many surface finishes are required by customers who manufacture a multitude of objects of sheet metal. The sheets may be annealed either by being passed slowly through a long furnace with hot central zone (blue annealing) or by being piled in a tight box containing a prepared atmosphere to protect the steel from tarnish and heated for hours at a considerably lower temperature (box annealing); or the cold sheets may be given several passes through accurate rolls for a smooth surface and a somewhat stiffer temper. Interspersed with these operations, the oxide or mill scale may be removed by pickling in weak sulfuric acid. Finally, the cleaned cold-rolled sheets may be dipped in white metal for a protective coat, wiped, cooled, polished and boxed. Coating with zinc is called galvanizing; tin or tin sheet is thin steel dipped in pure tin; terne sheet is dipped in a lead-tin alloy.

3. Strip and Continuous Sheets.—The 1930s saw a replacement of hand mills by continuous sheet mills, especially in the United States. Since 1900 it was common to roll strip up to 3 in. wide and 16 gauge or less in thickness in very long coils in a series of roll stands placed close together; mills have been built for wider and wider strip sheet, and sheet 8 ft. wide has been produced commercially in the United States since 1939.

In a narrow strip, hoop or cotton-tie mill, a continuous heating furnace feeds flat bars about the width of the finished piece endways into the first of a series of six tongue-and-groove rolls, perhaps ten inches in diameter. One edger may be installed after the third roll, and the remainder then be flat rolls. Then the bar passes through a series of three very accurate finishing rolls, sometimes being bent sharply, scraped and air blasted to remove the scale before entering the last roll. These finishing rolls are cylindrical, and the guides are shifted sideways at frequent intervals to prevent the chilled strip from wearing the roll surface irregularly; speeds are watched closely; the first roughing roll is very slow, the last very fast; in fact, the trailing end of the billet may still be in the furnace when the front end is being reeled, 200 ft. away, at the speed of 1,000 ft. per minute. One great advantage of such close-set continuous mills is that the time of passage from furnace to finishing roll is the same for all parts of the billet; consequently the temperature at the last pass is uniform, and the thickness after cooling is also quite uniform. Finished strip is automatically turned on edge, looped back and forth on a broad, slow-moving conveyor belt passing through a muffle; emerging, it is cool enough for reeling, cutting to length and bundling. Such a strip mill can produce from 10 to 20 tons of strip per hour, depending upon its width and gauge. The strip has a surface covered with mill scale, or, if this is scraped off, a blued colour formed during slow cooling. For higher finishes and stiffer tempers, the strip may be pickled and cold-rolled rather slowly to accurate gauge and smooth surface.

In modern continuous sheet mills, slabs weighing up to a ton and a half, the product of a blooming mill, are reheated to the proper temperature and delivered to the first roll stand, where jets of high pressure, superheated steam strike the hot slab just as it enters the rolls, thus breaking loose most of the scale. This roll stand is set somewhat further from its successors than the space between later stands. Some of this table is utilized for a turning mechanism, so that the slab can be turned sideways, since its original length should represent the width of the strip. Heavy machinery holds the slab down while its edges are squeezed to the correct distance apart. The slab is also held here a little time to radiate down to the necessary temperature; the latter is fixed by the speed of the remaining stands and the desired delivery temperature. Once started on its way, the slab passes through three or four heavy, four-high roll stands comprising what is known as the roughing train, separated far enough so the slab is entirely free in its passage along the roller table from stand to stand. This roughing train will reduce the thickness of the 4½- to 5-in. slab to somewhere around 1 in., and correspondingly increase its length. It is usual for these stands also to have vertical edging rolls set at their entering side to keep the width of the hot metal correct. The work rolls in all these four-high mills are relatively small in diameter and have very heavy, massive backing-up rolls. Next in train comes a series of six four-high stands set fairly close together, each one rotating at a faster speed than its predecessor, the last one delivering sheet of required thickness from, say, ¼ in. down to $\frac{1}{16}$ in., at a speed of 30 m.p.h. The metal emerges from the last stand before the trailing end is clear of the first, so safe passage without breaking requires electronic control of the speed of the mills, as well as accurate and ready adjustment of the clearance between rolls, that is, the relative amount of reduction, stand to stand. Temperature of delivery of the sheet is important for many applications. Instantaneous and automatic optical pyrometers, indicating and recording temperatures not only of the slab at the beginning, but of the finished sheet at the end, are essential items of equipment. Sometimes the hot-finished sheet is rapidly cooled by water sprays; at other times the sheet is delivered as hot as possible to the coiling devices and the tightly wound coil is cooled quite slowly.

This sheet-mill product may be cut or slit into such sizes as make it available for other operations, such as thin plate or thick sheet for tankage or barrels, or it may be slit into narrow strips suitable for making into pipe. However, if most of it is to be further rolled into thinner sheet, the mill scale is pickled off and then the material is rolled through four-high cold-rolling mills, usually set three in tandem. Reduced finally to the proper thickness and hardness, the coil is uncoiled through a leveler and automatic shear that cuts and piles the sheets, after which they are sent to the annealing department for proper annealing. This is now done in controlled atmosphere so that there is no scaling and little discoloration. After a final pass through a four-high stand ("skin-rolling and leveling"), the sheets are resquared, inspected, oiled and shipped.

The necessary amount of cold reduction after annealing and pickling is frequently done in one cluster mill with work rolls rather small in diameter, each backed up by a larger roll which, in turn, is backed up by two other rolls. This gives a very stout assemblage with minimum elastic spring in the rolls and consequently produces sheet with minimum variation in thickness, edge to centre. An adjunct is two power-driven reels, one on each side of the stand. A coil of sheet is placed on one and the end threaded between work rolls and attached to the reel on the far side. The work rolls are screwed down by powerful motors, and the mill started up; the reel on the exit side puts heavy tension on the emerging sheet, the reel on the entering side holds back stoutly. Just before the end of the coil is reached, the mill reverses, the work rolls are screwed closer and the two reels reverse their functions. The combination of small rolls squezing the sheet, which at the same time is pulled forward between them, permits much heavier reductions per pass and more passes before the process must be interrupted for a softening anneal. A careful combination of rolling and annealing will control the grain size of the resulting sheet. Furthermore, grains can be caused to be oriented predominately in one direction—an important consideration in silicon steel used for electrical machinery. (*See* also ANNEALING; GALVANIZED IRON AND STEEL; TIN PLATE AND TERNEPLATE.)

4. Pipe.—Skelp, the flat bars from which small-sized pipe is made, is rolled in a continuous mill specially designed to produce bars true in thickness, width and properly beveled on the edges. Sometimes the finishing stand is adjustable, and a skilled workman varies the roll spacing slightly in accordance with his estimate of the temperature of the metal issuing, thus compensating for the different amounts of contraction during cooling. Skelp is cut 20 ft. long, one end pointed, and then charged into a flat hearth, properly designed to produce a uniform white heat throughout; when reaching the welding temperature the metal appears to be covered with

a shiny grease, which is molten iron oxide. The white-hot bar is drawn through a welding bell (fig. 4[A]) forming the flat bar into a tube and pressing the butted ends together into a true weld all in one operation. Further operations reduce the pipe, but only slightly, to the correct size, straighten it, remove the scale, shape and thread the ends, proof test it and finally cover it with a protective coating. Skelp for lap welding and butt welding is of plain low-carbon steel (.10% carbon); the harder varieties and alloys are not amenable to such simple forge welding practices.

Butt welding is done on pipe from $\frac{1}{8}$ to 3 in. nominal inside diameter. Common pipe from two to eight inches is more usually made of flat plate by lap welding (see fig. 4[B]). Plates are piled into a furnace, heated to a dull red and run one by one through scarfing rolls, which form the necessary bevel on the edges for an overlapping seam. The hot steel is then drawn through a forming bell that curls it up into a tube (fig. 4[A]). After reheating to the welding temperature, this tube is caught between a pair of rolls and rolled over a manganese steel mandrel (fig. 4[B]), and the joint welded by the high temperature and pressure at the point of contact. When the length has been rolled, the bar that has been holding the mandrel in position is withdrawn from the far end of the pipe, and the latter rolled away for the finishing operations already enumerated. It requires only a few seconds to weld a standard length pipe by either of these processes. Welded pipe over 30 in. in diameter is made by hammer welding or by automatic arc welding. In the former, the wide plate is curled on plate-bending rolls and the overlapping joint heated and forged shut in sections (*see* fig. 4[C]). After welding, the length is rerolled for shape and annealed, the ends sized and shaped and the pieces tested and dipped in anticorrosive liquid.

For arc welding, the edges of the plate are planed to a beveled V opening (fig. 4[D]), the pipe bent to shape in rolls, clamped between long copper bars and the bevel filled with metal from a slowly traveling wire, from which an electric arc is struck to the steel plate below. Another common method of making welded pipe uses resistance heating. A plate of necessary width and thickness is bent into a U by a series of rolls and then the U is closed into an O by further forming rolls in the train. This formed tube is then passed between two sets of rolls shaped so as to squeeze the joint tightly together; midway between are electrodes—copper disks, one on each side of the joint—which pass enough current to heat the adjoining edges continuously to welding temperature. Electric welded pipe can be made in higher carbon (harder) and alloy (stronger) steels than those used for butt and lap welding. (*See* also WELDING.)

5. Seamless Tubing.—In the United States, seamless tubing is preferred for all purposes where the internal pressure is high and service severe, and an increasing amount of such pipe is being made in diameters up to 18 in. First, a round billet at full red heat is pierced by inclined rolls and mandrel. As sketched in fig. 4(E), two 36-in. rolls of special shape are set side by side, with axes crossing and about 10° askew. The shape is such that the rolls grip the end of the ingot and move it forward slowly, forcing it over a mandrel set between them. The operation is such that the mandrel seeks and maintains a truly axial position. After piercing, the inner and outer surfaces are smoothed and the tube brought to exact size by several rollings over a mandrel, as in lap welding. Further operations from straightening to shipping are performed with considerable care. Not only is such pipe more reliable for the lack of any welded seam, but the piercing operation is so strenuous that nothing but metal of good quality can endure it. Therefore, the tubing can safely withstand a considerably higher pressure than the best of welded pipe. Seamless piping is used for all high-pressure fluids in power plants and in chemical, petroleum and process industries, the analysis of the steel being adjusted to the pressure, temperature and corrosive environment to be endured.

Plain carbon seamless tubes, after cold-drawing to thin walls, are much used for structural members on bicycles and for shaping into metal furniture and machine parts. Cold-drawing is done as sketched in fig. 4(F). A tube somewhat too large and thick in wall has the end swaged down slightly. All oxide is then pickled off, the tube washed, dried and dipped in tallow or other lubricant. The pointed end is thrust through a round die and gripped by draw-bench tongs. Next, a mandrel is thrust through the tube from the far end until it has a position directly within the die, and then the tube drawn forcibly through the annular opening thus formed. In this way, the outer and inner diameter may both be controlled. Each draw hardens and strengthens the metal and makes it more

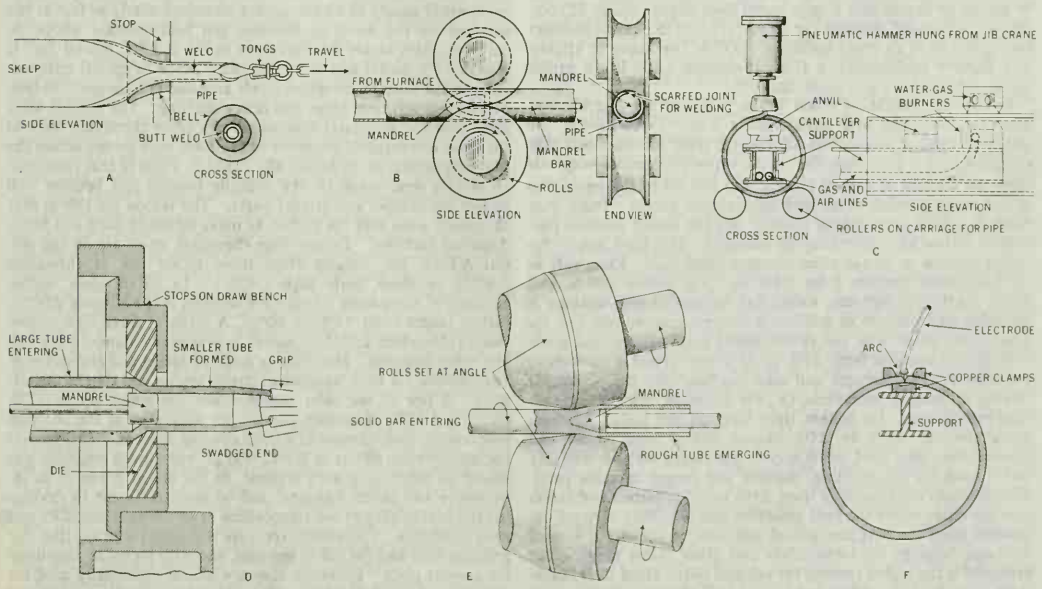

FIG. 4.—VARIOUS METHODS OF MANUFACTURING PIPE: (A) BUTT WELDING A 2-IN. PIPE; (B) LAP WELDING; (C) HAMMER WELDING OF 30-IN. PIPE; (D) DRAWING SEAMLESS PIPE; (E) MANNESMANN METHOD; (F) ARC WELDING OF 30-IN. PIPE

brittle; after a few such passes, if the required size is not yet reached, the pipe is given a low-temperature anneal to relieve the cold-working strains and the process continued.

6. Rods and Wire.—As indicated above, wire rods are frequently rolled from two-inch billets, 30 ft. long, on continuous mills, and the 16th or finishing pass delivers a .2 in. round to reels at a speed of 45 m.p.h. Such a mill will produce 15 tons per hour. Other arrangements utilize a continuous mill for breaking down a four-inch billet, and about a dozen loops fed by hand in a cross-country mill to finish. Rod reels are dumped automatically, and the rod cold-drawn through dies, with frequent annealings and other intermediate operations, into wire of various diameters, finishes and tempers. Most of this wire is stranded into cable or wire rope, woven into screens, netting, fencing or made into nails. *See* also WIRE.

X. PROPERTIES AND USES OF CARBON AND ALLOY STEELS

Any classification that accounts for the destination of steel made by any combination of the processes described above must evidently be impossible because of its complexity. As to process, it may be said that any of them can be made to produce steel that easily passes commercial specifications, even for so severe a duty as railroad rails. Somewhat over 40% of U.S. production is in the form of sheet, strip and tin plate and about 16% in bars, 12%–13% in pipe and 9%–10% in wire and wire products. Structural shapes account for 6%–7%, track material about 2½% (down from 5% before World War II) and miscellaneous products make up the balance, about 3%. A feature of the industry in the United States has been a large increase in sheet production and a rapid decline of track material.

The automobile industry consumes 17% of U.S. production and, in addition, absorbs quantities from warehouses and from forge shops and other converters and processors. About 12% of the total production goes into construction (in structural shapes and concrete reinforcement), 9% into containers and 6% into machinery. Export accounts for 4% and all other uses 32%. In England and the continent the proportion of exports is very much larger than in the U.S., and the consumption for automobiles is less.

An idea of the amount of steel required for modern products may be gained by saying that a large ocean liner might require 35,000,000 lb., a railroad sleeping car about 115,000 lb., a 50-passenger bus 13,000 lb., a six-room residence 5,000 lb. (exclusive of kitchen and laundry equipment), a U.S. automobile 3,500 lb., a garden spade 5 lb. and a 1-gal. paint can 1 lb.

1. Carbon Steels.—Carbon is the principal alloying element used for hardening and strengthening iron. Consequently the utility of various iron-carbon alloys—the plain carbon steels that comprise such a large majority of the entire production—depends upon the amount of carbon present and has led to the separation of the entire possible range into approximate grades. Ingot iron, made in a basic open-hearth furnace, has the lowest possible content of carbon and other alloying elements. It is used largely for sheets because of its corrosion resistant properties. Extra-soft or dead-soft steel contains from .08% to .18% carbon and is used where ductility, toughness, weldability or ease in cold-working is desirable and strength or stiffness a minor consideration, *i.e.*, for pipe, rivets, sheet, wire and casehardened parts. Structural grade or mild steel contains from .15% to .25% carbon and is used where a combination of strength and easy machinability is desired, for forging or flanging operations, *i.e.*, for buildings, bridges and railroad rolling stock, for boilers, drop forgings and bolts. Medium grade contains .25% to .35% carbon and is even harder and stronger than mild steel, yet it may be hot-forged without difficulty and is used for shipbuilding, shafting and forged machine parts. Medium-hard steel contains from .35% to .65% carbon and enters into the range where the final condition and reliability is much dependent upon the past mechanical and heat treatment; it is used for large forgings for locomotives and other prime movers, car axles and in the higher carbons for railroad rails. Hard steel ranges from .65% to .85% carbon and is used only after it is heat-treated to a correct combination of strength and ductility; it is used for wrought steel wheels, locomotive tires, woodcutting tools and sledges. Spring grades range from .85% to 1.05% and are used in a heat-treated condition, wherein a great range of hardness, resiliency and brittleness is possible, *i.e.*, automobile springs, cold chisels, rock drills and shear blades are made of these steels. High-carbon tool steels range from 1.05% to 1.20% and are used only after heat-treatment for railroad springs, metal-cutting and forming tools. A characteristic of these carbon steels is that each .01% of carbon increases the ultimate strength in the annealed condition by approximately 1,000 p.s.i., but at the expense of ductility or toughness. Hardness also is increased.

2. Alloy Steels.—Combinations of even higher strengths with considerable ductility and impact resistance may be had only in alloy steels, of which a number have been developed with special properties. (*See* also ALLOYS.)

Use of alloy steels, which prior to 1910 was confined mostly to big guns, armour and projectiles, has spread rapidly into all metal-working industries, among which the automotive leads. Production statistics are either lacking or uncertain because there is no agreement as to what constitutes an alloy steel. The trend is toward lower and lower contents of alloy made by basic open-hearth furnaces and by basic oxygen, or oxygen-lance, converters, operating under very special control for deoxidation and grain size. (*See* STEELS, ALLOY.) They are special steels, not merely a carbon steel to which alloying elements like nickel, chromium or manganese have been added. Production of such material is about 9% of the total steel made in the United States.

Nickel and Chromium.—Although there are infinite possibilities in alloying, by far the most important steels are those containing nickel and chromium; they are used for crankshafts, axles, gears and other automotive and machine parts. Relatively few analyses would be used in a single plant, the tendency being to minimize the number of alloy steels in process so as to avoid mixtures of the stock. A revised list of standard alloy steels issued in the late 1950s by the American Iron and Steel institute (A.I.S.I.) and the Society of Automotive Engineers contained 107 analyses. With the advent of alloy steels into ordnance and armour, nickel was the favourite element. It goes into solid solution in the ferrite and progressively adds to strength, but does not decrease toughness even without precise heat-treatment (*see* NICKEL STEEL). However, world supply of nickel has not increased nearly as fast as the demand for the metal in stainless and heat-resistant alloys, so only one plain nickel steel survives in the A.I.S.I. official list; it contains 5% nickel and 0.17% carbon. Made to special analyses, annealed or normalized nickel steels are used in long-span bridges, pressure vessels, gun tubes and heavy shafting. The earliest alloy steel used for structural purposes was a plain chromium steel in the main compression members of the Eads arch bridge across the Mississippi river at St. Louis, Mo. (1874). Prior to that time, cast chromium steel made by the crucible process had become well known for crusher and grinder parts. The reason for this is that chromium joins with the carbon to make intensely hard and finely dispersed carbides. Twenty-four chromium steels are on the official A.I.S.I. list, ranging from those rather low in chromium (.30%) to those fairly high (.80%). In all of them sizable amounts of manganese (.80%) are counted in the alloying effects; carbon ranges from .15% to .60%. A series of three high-carbon steels (chromium 1.25% or more) is practically standard for ball and roller bearings. Much use is made of nickel and chromium in combination for their hardening, strengthening and toughening effects. A few of the older combinations containing up to 3.5% nickel and 1.5% chromium persist, but nearly all of the analyses now contain molybdenum as a third alloying element. This reflects the conservation efforts of World War II, when much emphasis was placed on minimizing alloy content, on the use of boron as an inexpensive and potent hardener and on heat-treatment to develop the full potentiality of the composition as to strength, ductility and wear resistance. Chromium steels are still used for projectiles, for grinding rolls and for roller bearings, and with nickel or vanadium for armour plate. However, they are almost universally used for heat-treated machine parts, axles and gears. Rustless irons and steels contain 12% to 18% chromium and up to 8% nickel. (*See*

also STAINLESS STEEL.) Heat-resistant steels contain up to 25% of each alloying element.

Manganese is present in all steel, but when it adds up to between 1.0% and 2.0%, with carbon .30% to .50%, the steel acquires special properties. These analyses are favoured in the United States for high-strength castings, heat-treated forgings, rifle barrels and for casehardening. The U.S. standard list contains four medium-carbon steels with 1.75% manganese, used to an increasing extent in the automotive and farm equipment field, since they carry the least expensive alloy addition. So-called silicon structural steel used in long-span bridges and for boiler plate is one of the lower manganese steels of this classification. The tough Hadfield manganese steel, used in castings for shock and wear resistance, contains 11% or 12% manganese and 1.0% to 1.2% carbon.

Vanadium is an element that has a powerful deoxidizing and scavenging effect; thus a vanadium treatment on steel that shows very little of the element in the analysis makes for soundness, fine grain structure and reliability in forgings. From .5% to 2.0% is added along with other alloying elements to make high-speed steels and tools for hot work.

Molybdenum is added to chromium, nickel and chromium-nickel steels in from .2% to .3% to widen the range of heat-treatment for given values and to improve the forging and machining properties and their resistance to creep when working at high temperature. Carbon-molybdenum steels of controlled grain size and hardenability are favoured by many U.S. metallurgists, 11 such steels comprising the so-called 4,000 series. Molybdenum is readily available as an alloying element; in fact nearly three-quarters of the U.S. standard steels contains .25%. It deepens the hardened surface in quenched steels, resists coarsening of grain during high heating for forging and hardening and raises the creep resistance at moderately elevated temperatures.

Boron.—Prior to World War II, U.S. ferroalloy producers were marketing various trade-named "intensifiers" containing various amounts of deoxidizers such as titanium and silicon and grain refiners such as vanadium and aluminum, but, in addition, minor percentages of boron. The effect of the latter was to increase hardenability, which it did so effectively that, in the wartime emergency of 1940–45, the so-called "National Emergency Steels" (designed to minimize amounts of chromium, nickel and molybdenum) were further fortified with .0005% boron that enabled the combined alloy content to be again reduced by half; 17 of these low-alloy boron steels are still listed in the A.I.S.I. standards.

Hardenability Bands.—It has long been known that the properties induced in heat-treated steels are not additive, which is to say that a certain hardness induced either by $x\%$ of chromium or $y\%$ of molybdenum can be achieved by less than $x + y\%$ of the two in combination. It has also been demonstrated that many of the useful properties of steels in service are related to the hardness of the piece after it has been fully quenched and tempered. Likewise that the depth below the surface that can be fully quenched to the hard metallographic structure called martensite (described below) depends primarily on the alloying combination, whereas the surface hardness depends primarily on the carbon content. For nearly all engineering purposes, therefore, the metallurgist is interested in supplying metal that will harden to the centre in the size being quenched and in the quenching medium adopted. This will give a piece of uniform strength, hardness and endurance measurable by surface tests. It is generally immaterial what combination of alloys will do this. For this reason the Jominy end-quench test is widely used for assigning correct steels and heat-treatments to parts for severe services. In this test a one-inch round specimen four inches long, heated to normal hardening temperature, is placed in a fixture so a jet of cold water sprays on one end only. After the piece is cold, hardness tests are made at $\frac{1}{16}$-in. intervals from end to end, and the metallurgist can then identify the proper steel by its response to hardening rather than by its chemical composition. The A.I.S.I.'s standards contain 80 steels whose hardenability bands (plots showing maximum and minimum allowable hardness in the Jominy end-quench test) are specified.

High-Speed Steel.—Carbon tool steels for cutting metals are heat-treated by quenching from a high temperature, which gives them hardness, and then by reheating or tempering to a moderate degree to restore toughness. In use they must be operated at such low speeds that the friction between chip and tool nose will not reheat the cutting edge above the drawing temperature, else the hardness and usefulness of the tool is destroyed. Better speeds could be made by using self-hardening tool steels, those which are hard after a slow cooling from a high temperature, such as the patented tungsten-manganese alloy invented by Mushet in England sometime between 1860 and 1870, or the chromium-tungsten substitutes adapted by some U.S. steelmakers. During a 26-year research into the art of cutting metals, Frederick W. Taylor and Maunsel White discovered, 1898 to 1900, that if these steels were quenched from an austenitizing temperature so high that it would utterly ruin a carbon steel, the hardness would be retained even when the cutting speed was so high that the nose of the tool and the chip leaving it were red hot. Modern high-speed steels possessing this property of red hardness fall into four general classes as shown in Table V.

TABLE V.—*High-Speed Steels*

Alloying Element	High tungsten (%)	Low tungsten (%)	Molybdenum (%)	Cobalt (%)
Carbon	0.65	0.75	0.85	0.75
Tungsten	18.0	14.0	1.5	18.0
Chromium	4.0	4.0	4.25	4.0
Vanadium	1.0	2.0	1.0	2.0
Molybdenum	...	...	8.0	...
Cobalt	...	...	...	8.0

These are crucible or electric steels carefully forged to break up the crystals of complex carbides forming during the solidification of the ingot and distribute them evenly throughout the bar. A well-annealed bar is not very hard (Brinell 240) and can be machined into a complex tool like a milling cutter and then heat-treated; preheated to 850° C., heated rapidly to 1,300° C., cooled in oil or an air blast, giving a Brinell hardness of at least 600. Reheating 30 minutes at 600° C. is then necessary to give the quality of red hardness; the Brinell hardness is even higher and the toughness materially better. As an indication of the revolution that these steels have effected in machine-shop practice, a plain carbon tool steel will cut 16 ft. per minute on a medium-steel forging, a self-hardening steel 26 ft. per minute, the same after being given the high quench 60 ft. per minute and a modern high-speed steel 100 ft. per minute or more, all cuts being of same depth and feed and on the same material. Cobalt high speeds are for cutting extra-hard or gritty substances.

Tungsten Steels.—Other alloys whose properties are due principally to tungsten, in addition to the air- or self-hardening tool steels and the high-speed steels, are tool steels to which from 1% to 5% tungsten is added to improve the quality of the woodworking or other tools that would be made of the plain carbon steels. They are also good for making finishing cuts on metal after most of it has been removed by deep cuts with high-speed steel. Magnets are also made of steels with 6% tungsten and .7% carbon, quenched but not tempered.

Other Tool Steels.—A wide variety of tool steels is marketed for special purposes, reflecting in part the lack of standardization in this highly competitive industry. Among the most important are the oil-hardening, nondeforming steels containing about 1% each carbon, tungsten, chromium and manganese. Complex tools made of such steels can be hardened with minimum change of dimension to high hardness, retaining this high hardness (Rockwell C-63) after a toughening temper and maintaining a keen edge for cutting purposes. Tools for cold-working, such as forming dies, punches and thread rolling dies, contain either 1% carbon, 5% chromium and 1% molybdenum and are air-hardening, or 2.25% carbon, 11.5% chromium and .5% vanadium and are oil-hardening. The latter is exceedingly tough and wear resistant. Die steels for hot work comprise another major group; they are sometimes called semi-high-speed steels and contain about .3% carbon, 12% tungsten, 3% chromium and .4% vanadium. Their characteristic is abrasion resistance even when their surface is heated by being in contact with steel at forging heat.

XI. SOME FERROALLOYS

Ferroalloys are highly important and include those metallic substances used for finishing carbon steel and manufacturing alloy steel. Most of them are electric-furnace alloys of iron and carbon plus the third distinguishing metal, manganese, silicon, chromium or some other, although for some purposes the carbon content must be as low as possible. For such specifications, the alloys are made using either metallic aluminium or silicon for the reducing agent. A growing amount of pure metal—manganese or chromium made by electrodeposition—is also used for extra low-carbon steels or the so-called superalloys for high-temperature service.

It was early discovered that manganese must be added to make sound steel by Bessemer's process. As already noted, the usual ferroalloy for this purpose is spiegeleisen, a blast furnace product made from iron ore sufficiently high in manganese to smelt into a pig iron containing 10% to 30% of that element, with carbon about 5%. Spiegel cannot be used for low-carbon steels because the required amount of manganese carries with it too much carbon. For such purposes, ferromanganese is used, containing nominally 80% manganese and 6¾% carbon. This is also a product of the blast furnace when smelting an ore containing 40% to 50% manganese, low in iron. Since manganese and iron are so alike chemically, the actions in the furnace are very similar to those previously described. The output in ferromanganese from 50% ore is only about one-third as much as though common pig iron were produced; the blast is about 120° C. hotter and the coke consumption twice as much; about one-fifth of the manganese is lost in the slag. While ferromanganese can be made in an electric furnace of the pit type, it cannot compete with the blast-furnace product except under special economic conditions, as in Norway, or where carbon below .25% is required, as for high-manganese alloy steels.

Ferrosilicon is the next most important alloy. A 12% silicon pig iron may be made in the blast furnace, but alloys higher in silicon are now used to deoxidize nearly all steel for castings, most tonnage steel from basic open-hearth furnaces and to make several silicon alloy steels. Ferrosilicons are exclusively an electric furnace product and are made in several grades—50%, 75%, 80% and 95%. Carbon is about .5%, phosphorus and sulfur less than .10%—the former particularly must be kept to the minimum to prevent the alloy from absorbing moisture from the air and generating poisonous phosgene gas (PH_3). A shallow electric furnace is employed, rectangular in cross section, with bottom built of carbon blocks. Through the roof are suspended three carbon electrodes, one for each phase of current; a granular mixture of pure quartzite, clean iron turnings and coke is shoveled into the open top, filling the entire furnace. Passage of current from electrodes to furnace bottom gives the necessary heat for the coke to reduce silicon metal from the rock. Carbon monoxide produced by the reaction rises and burns at the top of the charge column, and a molten alloy of iron and silicon collects within the coke mass accumulated on the hearth, from which it is periodically drained.

Ferrochromium.—This is one of the earliest ferroalloys produced in an electric furnace. Commercial alloys contain about 67% chromium. The so-called high-carbon alloys range from 4% to 8% carbon by units, whereas the low-carbon alloys necessary to make stainless irons range from .20% to 2.0% carbon by steps. Chromium metal of high purity is also commercial. Ferrochromiums are ordinarily made in closed furnaces of the Heroult type, with bottoms laid in carbon blocks. A charge of chromium ore, iron or iron ore, anthracite coal for reducing and flux for slagging impurities is mixed and shoveled in, the doors closed and electric current turned on. Carbon reduces the metallic oxides in the intense localized heat; at the finish, the molten charge is poured into slabs, broken, analyzed and graded for shipment. To reduce high carbon, these varieties are remelted with concentrated chromium oxide; under a lime-fluorspar slag, or, as noted above, prepared from high carbon ferrochromium by electrolysis.

Nickel is added to molten steel as shot metal, or a nickel-steel scrap may be used to make alloy steel—nickel having little tendency to enter the furnace slag.

Ferrovanadium is one of the most difficult alloys to make, because of the activity of the element. The pure metal is not used in steelmaking but is available for many special applications. B. D. Saklatwalla developed various means of commercial alloy production, using a mixture of vanadium oxide, iron oxide and powdered aluminium, either in crucibles by means of the thermit reaction or in shaft furnaces with the assistance of the electric arc. In the United States, the ore is melted in a reverberatory furnace, and the vanadium concentrated in the slag. This slag is ground, mixed with carbon, iron scale and fluxes (broken glass, lime and fluorspar) and fed in a fine stream into a covered furnace, directly through the arc between graphite electrodes, thus effecting the reduction almost instantly in the intense heat. Reduced alloy and slag collect in the hearth and are tapped three or four times a day. A common analysis contains 35% vanadium.

Ferrotungsten.—Tungsten ore is widely distributed, and the concentrate comes to the refiner in such complex mixtures of minerals that frequently the first step is the production of the oxide WO_3 by chemical means (*see* TUNGSTEN STEEL). This oxide is easily reduced to metallic powder without melting by mixing with fine carbon, sealing in a crucible and heating to 1,300° C. for several hours. Ferrotungsten, which has become more popular for making high-speed steel, may contain from 60% to 85% tungsten and is made in single-phase electric-shaft furnaces. The bottom is one terminal; the electrode set above is surrounded by a shaft of loose brickwork, and a mixture of oxide ore, iron and carbon is filled in. As the reduced alloy builds up on the hearth, it chills into a thicker and thicker button, because it has an unusually high melting point; when this solid metallic mass has grown to a point where its electrical resistance interferes with operations, the temporary furnace is torn down and the sow (metallic mass) crushed, analyzed and classified.

XII. METALLOGRAPHY AND HEAT-TREATMENT

1. General Structure of Steel.—Much may be discovered about the general structure of the metal by a close scrutiny with the naked eye or with a magnifying glass. Such studies (macroscopy) include examination of the finished surfaces, of freshly broken fractures and of roughly polished sections etched in various ways. Information gained from a freshly broken fracture has not yet been systematized and correlated with microscopic appearance except as to grain size of the steel after heat-treatment. To be of value it requires a keen eye, much practice and everyday familiarity with the fracture of satisfactory metal to note small differences. In the hands of a skilled inspector it is the first step in securing uniformity in raw materials. In fact this was the only means available to the iron- and steelworker up to the 20th century.

General structure may best be exhibited on a roughly polished surface by etching in freshly prepared ammonium persulfate solution, 10% $(NH_4)_2S_2O_8$. It shows immediately differences in grain size caused by differences in heat-treatment or other cause.

Deep etching is much favoured in the U.S. for acceptance tests on high-grade steel. It shows any nonuniformity in chemical composition or general bad quality. The smooth sample is held in hot hydrochloric acid (diluted 50%) for about 30 minutes. Impure spots, blowholes or cracks are eaten more deeply than elsewhere, and the result is an irregularly pitted surface.

During solidification of a steel ingot, excess of sulfur compounds will collect toward the centre and top part, where they are trapped and remain during further rolling and manufacture. The distribution of sulfur compounds in a smooth section may be shown by pressing it firmly for about a minute against a sheet of photographic paper moistened with 2% sulfuric acid, then washing and fixing. The dark areas indicate the location of higher sulfur in the steel. Phosphorus also accumulates around the borders of the large metallic crystals that form in the ingot, and during rolling or forging are pressed out into stringers or sheets in ruling directions.

Ordinary plate or forging steel will always be found thus marked. In forging, these *flow lines* are arranged more or less parallel to the finished surface, and the dies are so constructed that the flow lines take an easy curve around corners. Any crinkling is associated with a weak, brittle region. To show phosphorus segregations, a polished surface is washed in alcohol and immersed in 10% copper-ammonium chloride. A thin, copper plate will coat

out on those portions low in phosphorus, leaving high-phosphorus regions bright.

The fact that the hardness, toughness and general properties of a piece of steel could be profoundly modified by a simple heating and cooling has been known since time immemorial; in fact, what is now known as steel was perhaps not recognized as having great merit until the fortunate discovery of heat-treatment was made. This is a quite mysterious happening, this heat-treatment, and it is not surprising that, down through the long centuries when the art was guarded as a closed secret, many superstitions arose regarding the efficacy of certain heating fires and quenching fluids. Within the past century the chemist and physicist have done much to clear up the mystery by analyzing the various operations; we now know the essential differences between the various steels, irons, fuels, atmospheres and quenching fluids. Only since the beginning of the 20th century, however, have intensive studies with the microscope, pyrometer, hardness- and tension-testing machines brought forth a knowledge of the changes that go forward in steel or iron during a heating and cooling cycle, and working hypotheses of the causes of hardening (*see* METALLOGRAPHY). Logically, an ingot in a soaking pit prior to rolling, or a billet in a heating furnace prior to forging, may be said to be undergoing heat-treatment, but from a workshop viewpoint the term is restricted to a heating and cooling to restore original ductility and workability in a partly finished piece, or a heating and cooling—sometimes repeated—to induce special properties in the finished article. (*See* also ANNEALING.)

2. Furnaces.—Furnace size depends upon the pieces to be treated and the temperature required. A well-designed furnace is one that easily attains the necessary temperature and maintains that temperature uniformly in all parts, with an atmosphere that does not deteriorate the furnace and yet has the desired effect, or no effect, upon the metal being treated. Fuels may be coke or coal, gas, oil or electricity. Choice of source of heat is merely a matter of which is the most convenient and economical. Gas and electricity are favoured because of their ease of manipulation to give uniform temperature—choice depends upon the relative cost per thermal unit and the atmosphere required. For instance, it is handiest to use electric resistors for heating elements in a furnace for annealing transformer sheets in a hydrogen atmosphere. Gas or oil fuel would probably be chosen for treatments on products such as roller bearings running into tons per day. Sometimes recuperators or regenerators are installed to save heat. Mechanical devices for handling the metal, such as charging machines, furnace bottoms built on wheels or moved on rollers, revolving heating muffles and conveyors, are installed wherever the weight of material receiving uniform treatment is great. Temperature control including the rate of increase in heat, duration at heat and speed of cooling is most important. Continuous furnaces are devised to maintain this cycle automatically. Batch furnaces are controlled by hand or by automatic control of the fuel burners through pyrometers, which indicate or make a permanent record of the temperature at all times. An important method of localized heating is by high-frequency currents; pieces such as crankshafts are rapidly heated one at a time at only those bearing surfaces that are to be hardened. (*See* also FURNACE, ELECTRIC; FURNACE, METALLURGICAL; HEAT-TREATMENT.)

3. Atmosphere.—The atmosphere within the furnace is important. In an open-flame furnace, scaling (the production of oxide on the metal's surface) may be minimized by feeding rather less air than the gas or oil requires for complete combustion. This deficiency of oxygen means that little or none will be available to react with the hot metal. In long heating of thin sheet, or long annealing of tool steel, where the surface must be preserved, the work is protected from the furnace atmosphere by closed boxes or tubes. For bright annealing, atmospheres of flue gas, partially burned fuel gas or even gas engine exhaust may be used; due to the comparatively low annealing temperature (650° C.) any mixture of an excess of carbon monoxide over carbon dioxide will protect the steel. It must be fairly dry to prevent tarnishing by steam on the cooling cycle. Protection during heating to higher temperatures (900° C.) for quenching is far more difficult because the reactions are much more rapid and the steel must neither oxidize nor gain or lose carbon. Such atmospheres are made in commercial generating equipment. One general type is known as endothermic because it requires auxiliary heat for its production. Methane, CH_4, and a deficiency of air are passed through a heated catalyst and cooled to a mixture of 40% nitrogen, 40% hydrogen and 20% carbon monoxide, a most useful gas whose "carbon potential," or tendency to add or subtract carbon from the surface of a given steel, can be easily regulated by adjusting the dew point or moisture content. The other and more widely used type of gas (exothermic) burns methane in a slight deficiency of air and contains varying amounts of CO_2, CO and H_2 depending on proportions of air and gas fed to the burner. Its reaction to hot steel depends on the relative amounts of carbon oxides and hydrogen and also on moisture content, the latter being easily reduced by refrigeration. By the addition of methane, the gas becomes useful for casehardening; further small additions of ammonia will make it suitable for carbonitriding or the production on a soft steel part of a thin, intensely hard surface high in both carbon and nitrogen. By catalyzing the CO to CO_2 and absorbing the latter, this exothermic gas can be converted to a mixture of nitrogen and hydrogen similar to dissociated ammonia and suitable for the heat-treatment of stainless steels. Casehardening is also done in the old manner—packing the parts in boxes with carbonaceous products that form the necessary gaseous atmosphere. In any event a "fine-grained" steel is used, one that resists grain growth for long times at the high temperature (925° C.) employed. These steels, as already pointed out, are well deoxidized and then alloyed with a fractional per cent of aluminum. (*See* also SURFACE HARDENING.)

4. Quenching.—This may be done in various liquids, depending upon the speed required. All kinds of solutions of outlandish materials have been used, but there is no virtue in a quenching fluid except the ability to abstract heat quickly. In practice, the most drastic quench is given by a properly disposed nest of nozzles that spray cold water at high pressure on the hot steel. Next comes a bath of iced brine, then cold water, then high flash point oil, then boiling water, then molten lead, then air blast, then quiet air—even slower cooling may be done in 8 hours by burial in lime; a dying furnace may require from 24 hours up to seven days. Quenching baths require methods for circulating the medium, maintaining its correct temperature either by heating or refrigerating coils and dashing it against the metal so no air or steam bubbles remain attached to the hot metal, else soft spots will occur on an otherwise hardened surface. Conveyors, or other mechanical methods of getting the hot metal rapidly into the quench and removing it when cold, are installed to save labour. In order to understand what goes on during these heating and cooling cycles, an introduction to the science of metallography and the so-called iron-carbon-equilibrium diagram is necessary.

5. Metallography.—Metallography is the study of the inner structure of metals and how this varies with the chemical composition of the alloy and its past heat-treatment or the work that has been done on it. It also includes the study of the relationship between the inner structure of metal and the physical properties, such as strength, toughness and hardness. In this study, the use of a microscope is a long step in advance of the ancient practice of breaking the metal and looking at the fracture. It enables the student to magnify the apparent size of the grains a thousandfold. A sample of the piece under study is given a high polish, etched slightly in a suitable acid and placed on a microscope stage with a special illuminating device for opaque objects (*see* MICROSCOPE). Much higher magnifications are available if the lens system is adapted to the use of ultraviolet light, and even greater enlargements revealing finer detail are obtainable through the electron microscope. The resulting structure may by appropriate means be photographed for permanent record and for study in connection with information on its past history, its physical strength, hardness or electrical characteristics. Important physical properties affected by heat-treatments include strength, toughness, hardness, electrical and magnetic characteristics and corrosion resistance. Of these, the first three are most relied upon. Machines and methods for

making tension tests and determining the ultimate strength, elastic limit and ductility are described under MATERIALS, STRENGTH OF. Hardness is measured by the size of impression left by a steel ball or a diamond cone or pyramid weighted down by a given load. Toughness or impact strength is measured by the amount of energy absorbed from a swinging hammer by the instantaneous fracture of a standardized test piece.

6. Evidence That Metal Is Crystalline.—Viewed through a microscope, an etched metal surface presents a mosaic patchwork of interlocking grains.

Much evidence is at hand to support the idea that these granules, despite their irregular boundaries, are crystalline, *i.e.*, the ultimate atoms are in an orderly geometric arrangement of rows and ranks. The fact was finally proven by X-rays in a manner easiest explained by this analogy: if a street lamp is viewed through a window screen, the brilliant centre appears to have a series of bright rays extending outward, caused by reflections of light from every wire so placed as to throw light back into the eyes. The geometric pattern of rays is caused by the geometric arrangement of the wires; arguing by analogy, if the atoms of metal are arranged in definite geometric patterns, then an X-ray beam penetrating the crystal would be reflected in definite ways and emerge in a geometric pattern; a mathematician can predict the atomic spacing and arrangement from the diffraction pattern so produced. Thus it is found that wrought iron at room temperature is in the body-centred cubic arrangement. That means that if the space occupied is subdivided by imaginary planes into a space-lattice of tiny cubes regularly placed on top and to both sides of one another, the iron atoms are located at the corner of each of these imaginary cubes, and each cube will have one atom in its centre. Some theoretical studies have postulated that the crystals may not be perfectly symmetrical but may have scattered imperfections and discontinuities. These have actually been photographed in certain salt crystals. Many changes in metallic properties, such as hardening by cold-work, plastic flow under stress and brittle fractures are theoretically explicable by this hypothesis. *See* ALLOYS: *Structure of Alloys;* CRYSTALS, DISLOCATION OF; HEAT-TREATMENT: *Recovery and Recrystallization.* (E. E. T.; R. E. GE.)

XIII. STEEL METALLURGY

A. Slowly Cooled Steels

Although commercial steels invariably contain several chemical elements, they are described as being essentially alloys of iron and carbon containing up to about 2% by weight of carbon. When more than 2% of carbon is present in a ferrous material, it is usually termed cast iron (*q.v.*).

The properties of a steel are primarily dependent on its structure; this is determined by the chemical composition of the steel, particularly its carbon content, and by the thermal and mechanical treatment it has received. Before attempting to assess the effects of chemical composition, it is essential to consider the structural changes that occur in pure iron when it is heated and cooled.

1. Allotropic Changes in Pure Iron.—Much information can be obtained about the structural changes in a metal by measuring the rate of temperature change of a sample of the metal when it is heated or cooled slowly. When no structural change occurs, the rate of temperature change will be fairly constant, but when the structure changes it results in an energy change that will temporarily decrease the rate of temperature change in the sample. Thus, when a sample of a pure metal melts, the latent heat of fusion is absorbed from the surroundings and, while this happens, the temperature of the sample remains constant at its melting point. This method, called thermal analysis, enables the temperatures of structural changes to be determined. The nature of structural changes is best examined by X-ray diffraction methods.

In pure iron, four changes are detectable by thermal analysis, at 768° C., 910° C., 1,390° C. and 1,539° C. At room temperature, the iron crystals have a body-centred cubic structure; that is, each crystal is composed of a regular pattern of atoms such that an atom can be considered to be in the centre of a cube and surrounded by eight equidistant neighbours, each of which is at a corner of the cube. This body-centred cubic form of iron is called α-iron, or ferrite (although more generally ferrite designates a solid solution in which α-iron is the solvent) and is magnetic at temperatures below 768° C. On being heated through 768° C., the α-iron loses its magnetism, in what is termed the A_2 change. The body-centred cubic structure exists up to 910° C. when the atoms regroup themselves into a face-centred cubic structure; in this latter structure the atoms are arranged in such a way that one is at each of the eight corners of a cube and one at the centre of each of the six faces of the cube. The structural change at 910° C. is called the A_3 change and the face-centred cubic structure is called γ-iron. Solid solutions in which γ-iron is the solvent are known as austenite, in honour of the British metallurgist Sir William C. Roberts-Austen. The face-centred cubic form is stable up to 1,390° C., at which the atoms regroup into a body-centred cubic structure. This is the A_4 change and the body-centred cubic structure formed is called δ-iron or δ-ferrite.

The final structural change is at 1,539° C. when δ-iron melts. On slow cooling, the reverse changes occur and in order to differentiate between changes on heating and those on cooling, the suffix *c* is used to represent a change during heating (*chauffage*), while the suffix *r* represents a change during cooling (*refroidissement*); thus, the Ac_3 change in iron is α-iron to γ-iron, while the Ar_3 is γ-iron to α-iron.

2. Effect of Carbon Content on Structure.—Only a very small amount of carbon can enter into solid solution with α-iron to form ferrite—0.025% by weight at 723° C., and less at lower temperatures. When a steel has cooled slowly to temperatures below 723° C., the carbon in excess of .025% forms a compound called cementite, Fe_3C. This compound is very hard and brittle, whereas ferrite is soft and tough. A steel containing 1.0% of carbon would, after slow cooling, consist of about six parts of the soft ferrite and one part of the very hard cementite, whereas a steel containing less carbon, say .3%, would contain more ferrite and less cementite. Thus, in slowly cooled steels, the hardness and strength increase with carbon content while the ductility and toughness decrease (*see* fig. 5). For this reason, steels of maximum ductility and toughness are of low-carbon content.

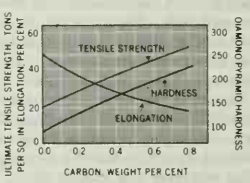

FIG. 5.—MECHANICAL PROPERTIES OF ANNEALED STEELS

Whereas in pure iron the A_3 change (α-iron $\rightleftharpoons$ γ-iron) occurs at 910° C., the addition of increasing amounts of carbon up to .8% decreases the temperature of this change progressively to 723° C. Gamma-iron will hold much more carbon in solid solution, forming austenite, than does ferrite—.8% at 723° C., and the amount increases with rise in temperature to 2.0% at 1,130° C. When the carbon content exceeds that which can enter into solid solution with austenite, the excess forms cementite.

The effects of temperature and carbon content on the structure of slowly cooled steels in the solid state are normally expressed as a diagram, called the "steel-portion of the iron-cementite phase diagram" (fig. 6). This diagram is not a true equilibrium diagram because cementite is not a truly stable phase—on annealing at high temperatures it slowly decomposes to graphite and austenite or to graphite and ferrite, depending on the annealing temperature; however, the diagram is used as the basis for steel heat-treatment because the decomposition of cementite does not normally occur at a sufficient rate to affect steel structures.

In order to illustrate the application of this phase diagram, it is convenient to consider three steels of different carbon contents. At temperature below 723° C., all slowly cooled steels consist of ferrite and cementite, the relative amounts depending on the carbon content.

Considering, first, a steel containing .8% by weight of carbon, the diagram shows that at temperatures above 723° C. the structure consists entirely of austenite. So, when the steel is heated to just above 723° C. (point E, fig. 6) the ferrite changes to austenite and, since this austenite can dissolve .8% of carbon, the cementite disappears. This change is known as the Ac_1 change.

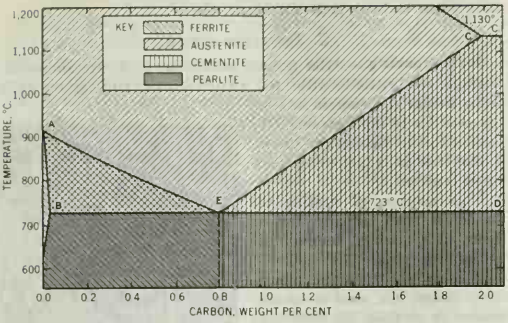

FIG. 6.—STEEL PORTION OF IRON-CEMENTITE DIAGRAM

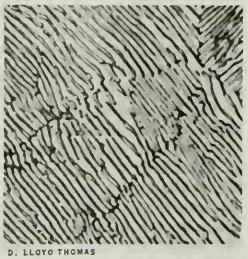
The austenite crystals thus formed are initially very small, but if heating is continued to some higher temperature, some crystals grow at the expense of others and so the austenite crystal size increases. When this steel is slowly cooled to below 723° C., the austenite decomposes into a mechanical mixture of ferrite and cementite—the Ar_1 change. This type of solid state change where a phase stable at high temperature decomposes on cooling to two or more different phases is called a eutectoid change, and, in the case of carbon steels, can be expressed as:

$$\gamma(0.8\%\ \text{C}) \underset{\text{Ac}_1}{\overset{\text{Ar}_1}{\rightleftharpoons}} \alpha(0.025\%\ \text{C}) + \text{Fe}_3\text{C}\ (6.67\%\ \text{C})$$

The eutectoid mixture of ferrite and cementite consists of alternating platelets of the two phases (lamellar structure, with pearly lustre) and is known as pearlite (fig. 7). The rate and extent of the decomposition and the coarseness of the pearlite structure produced are very much dependent on the rate at which the steel is cooled; this is discussed later.



D. LLOYD THOMAS

FIG. 7.—PEARLITE. ×1,000

When a steel of lower carbon content, say .3% by weight, is heated to just above 723° C. (line BE, fig. 6), austenite containing .8% carbon is formed from the cementite and some of the ferrite, while some of the ferrite is not affected; the structure is thus ferrite and austenite. As the temperature is increased, the austenite progressively absorbs the remaining ferrite and this absorption is complete at about 830° C.; *i.e.*, the temperature at which line AE (fig. 6) is equivalent to .3% carbon. The temperature range over which the structure changes from ferrite and cementite to austenite is known as the critical temperature range of the steel. Above the critical range, the steel consists entirely of austenite crystals whose size increases as the temperature is raised. The result of slowly cooling this steel through the critical range is, first, to allow ferrite crystals to form from the austenite. Since the ferrite will hold in solid solution only a very small amount of carbon, the austenite crystals become progressively enriched in carbon until, at about 723° C., they contain .8%. These austenite crystals then decompose to pearlite, so that the slowly cooled structure will consist of ferrite and pearlite (fig. 8). The ferrite crystals grow from the crystal boundaries of the austenite and so the final distribution of ferrite and pearlite will depend on the size of the austenite crystals, which in turn depends primarily on the temperature above the critical range to which the steel has been heated. Thus, if one sample of the steel is heated to 1,100° C. and another to 850° C., on slowly cooling the former will have a much coarser distribution of ferrite and pearlite than the latter, and the former is said to have been overheated. Whereas the hardness and tensile properties of an overheated steel are not appreciably different from those of a steel with a fine structure, the toughness measured on a notched test piece will be inferior to that of the fine-grained steel, and the overheated steel is liable to fracture in a brittle manner at temperatures at or just below those of the normal atmosphere (*see* MATERIALS, STRENGTH OF: *The Problem of Failure*). The overheated condition can be remedied by reheating the steel to just above the critical temperature range and cooling slowly.

G. LLOYD THOMAS

FIG. 8.—FERRITE (LIGHT) AND PEARLITE (DARK AND LAMELLAR). ×600

Heating of a steel containing more than .8% by weight carbon, say 1.2%, results in the ferrite and some cementite changing to austenite of .8% carbon content at just above 723° C.; as the temperature is raised further, the remaining cementite is progressively absorbed by the austenite, whose carbon content is thereby increased, until at temperatures above about 860° C., *i.e.*, the temperature at which line CE (fig. 6) is equivalent to 1.2% carbon, the steel consists entirely of austenite crystals that grow larger with rising temperature. On slowly cooling the steel, cementite begins to separate around the austenite crystals at about 860° C. and the austenite thereby becomes progressively depleted in carbon until at about 723° C. it contains .8%. This austenite then decomposes to pearlite, so that the structure is finally cementite and pearlite. This type of structure is very brittle because the hard cementite, having formed around the austenite crystals, is present as a continuous network. To overcome this, steels containing more than .8% carbon are forged while cooling to about 760° C., so that, as the cementite separates from the austenite, it is broken up and by this means dispersed.

After the steel has been forged this way, it is essential that any subsequent heat-treatment should not involve heating to a temperature above about 760° C.; otherwise the cementite that had been dispersed would dissolve in the austenite and, when the steel is cooled, would separate as an embrittling network.

See also HEAT-TREATMENT.

B. QUENCHED STEELS

1. Carbon Steels.—An eutectoid steel (.8% by weight carbon) when slowly cooled from above 723° C. transforms at a temperature of about 700° C. to a relatively coarse pearlite structure, *i.e.*, the platelets of ferrite and cementite are relatively thick and this structure is quite soft. If the cooling rate is increased, the first effect is that the temperature at which austenite transforms is progressively lowered with increase in cooling rate, to about 550° C.; this results in a refinement of the pearlite structure and an increase in hardness and strength. Thus the heat-treatment process of full annealing, which consists of cooling steel slowly in a furnace from a temperature just above the critical range, produces coarse pearlite, whereas normalizing, in which steel is allowed to cool freely in air, produces finer pearlite and therefore a somewhat harder, stronger but less ductile steel. When the cooling rate is very rapid, *e.g.*, when a small sample is quenched in cold water, the formation of pearlite is partially or completely suppressed and a very hard structure called martensite begins to form from any untransformed austenite at about 200° C.; when the steel has cooled to room temperature, almost all the austenite not transformed to pearlite will have changed to martensite (fig. 9).

D. LLOYD THOMAS

FIG. 9.—MARTENSITE. ×600

The minimum cooling rate that is necessary to produce a martensitic structure, *i.e.*, to suppress completely the formation of pearlite, is termed the critical cooling velocity of the steel and the formation of this martensitic structure is the aim of the heat-treatment process of quench-hardening.

In order to produce a martensitic structure in steels containing less than .8% carbon, and thus to harden them, it is necessary to quench from a temperature above the critical temperature range (usually about 50° C. above) so that both ferrite and pearlite separations are suppressed. Steels containing less than about .2% carbon cannot be readily hardened by quenching because the complete suppression of ferrite is more difficult as the carbon content of the steel decreases.

Furthermore, the hardness of the martensite decreases rapidly with decrease in carbon content, so that the degree of quench-hardening that can be attained in these low carbon steels is low.

When steels containing more than .8% carbon are to be hardened, they are quenched from 760° C., so that the dispersed cementite produced by forging is retained in a matrix of martensite; a mixture of cementite and martensite gives the maximum possible hardness to the steel.

2. The Hardness of Martensite.—Martensite is the product of face-centred cubic austenite with carbon in solution transforming to a body-centred cubic structure without precipitating cementite; *i.e.*, martensite is ferrite supersaturated with carbon. This supersaturation distorts the atomic arrangement from cubic to tetragonal, the distortion and tetragonality increasing with increasing carbon content.

Distortion is also caused by the expansion in volume that occurs when martensite forms and by the peculiar and characteristic mechanism of the transformation. The hardness of martensite is the result of the distortion of the crystal structure and increases rapidly with increase in carbon content (fig. 10).

3. Low-Alloy Steels.—In plain carbon steels, the critical cooling velocity is high, and this imposes severe limitations on the applications of quench-hardening to these steels. Rapid cooling rates introduce differential contraction in a steel component and thus give rise to large-scale distortion and, in severe cases, to cracking.

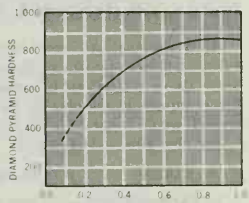


FIG. 10.—HARDNESS OF MARTENSITE

Furthermore, because the rate of cooling in the centre of a large section is appreciably less than in a small section, the thickness of plain carbon steel that can be effectively hardened throughout, even by such a drastic quench as cold water, is restricted to about $\frac{3}{4}$ in.

The addition of alloying elements, such as nickel, chromium, manganese and molybdenum, either singly or in combination, markedly reduces the critical cooling velocity and hence increases the so-called hardenability of steel. The hardness of martensite in plain carbon and in alloy steels is primarily dependent on the carbon content and not on the content of the other alloying elements, but these elements make the production of martensite easier.

By the use of alloying elements, it is thus possible to reduce the rate of cooling and thereby the dangers of large-scale distortion and cracking and, furthermore, much larger sections of steel can be hardened throughout. Thus, whereas in a carbon steel, the maximum section that can be effectively hardened is about $\frac{3}{4}$ in. and that by water quenching, in a typical nickel-chromium-molybdenum steel, sections of up to 6 in. can be hardened by oil quenching. Increased alloy additions can reduce the critical cooling velocity to such an extent that cooling in still air produces hardening; *i.e.*, whereas carbon steels are water-hardened, alloy steels may be oil-hardened or air-hardened. However, the cost of alloy steels is greater than that of carbon steels, the cost increasing with alloy content, and so generally alloy steels are used only when carbon steels are unsuitable.

C. Tempered Steels

1. Tempering.—After quench-hardening, steels are almost invariably too brittle to withstand service stresses and carbon steels in particular also contain internal stresses due to rapid cooling. To reduce the brittleness and the internal stresses, a tempering treatment is given.

D. LLOYD THOMAS
FIG. 11.—TEMPERED MARTENSITE. ×1,000

This consists of heating the hardened steel, usually for an hour, at a selected temperature within the range 200°–680° C., *i.e.*, below the critical temperature range; the steel is usually cooled in air from the tempering temperature.

Tempering results in the decomposition of martensite to ferrite and cementite, the extent of the decomposition increasing with tempering temperature up to about 400° C. Thus, whereas in martensite the carbon atoms are in enforced solid solution, in tempered martensite the carbon forms separate particles of the hard cementite compound, these particles being embedded in a soft and tough matrix of ferrite. The cementite particles are extremely small, their size increasing with increase of tempering temperature, but even those formed on tempering at 600° C. are only just resolved with an optical microscope at a magnification of 1,000 (fig. 11). Although tempering results in a loss of hardness and strength, the combinations of strength and toughness attainable by hardening and tempering are the best that can be produced in a steel. The structural reason for this is that whereas in annealed or normalized steels the cementite is present in pearlite as platelets that are to some extent embrittling, in hardened and tempered steels the cementite particles are much more finely dispersed and thus impart strength without brittleness.

The selection of tempering temperature controls the combination of hardness and strength on the one hand with toughness on the other: the higher the tempering temperature up to a maximum of about 680° C. the lower are the hardness and strength but the higher the toughness (fig. 12). Thus, in tool steels, the purpose of tempering is to relieve internal stresses without decreasing appreciably the hardness, and so tempering is usually done within the range 200°–250° C.; steel springs are tempered at 350°–500° C., whereas steels of medium-carbon content that have to withstand high stresses in service would generally be tempered at 550°–650° C. in order to develop the best toughness together with strength.

Alloy additions, such as nickel and chromium, as well as increasing the hardenability of steels, also confer better mechanical properties in the hardened and tempered condition, primarily because the additions strengthen the ferrite matrix. Thus, if a carbon steel and a nickel-chromium steel were treated to give the same strength, the nickel-chromium steel would have greater toughness than the carbon steel.

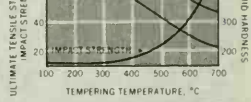

FIG. 12.—EFFECTS OF TEMPERING TEMPERATURE ON MECHANICAL PROPERTIES

In highly alloyed steels, the softening caused by tempering may be appreciably less than in carbon or low-alloy steels. This quality is utilized in high-speed tool steels which are hardened by quenching from very high temperatures, *e.g.*, 1,300° C., and tempered at 550°–600° C.; the tempering results in very little softening and in some cases the hardness increases—this is termed secondary hardening. The resistance to softening of these steels is of value when high temperatures are developed in service, such as in machine tools operating at high cutting speeds.

2. Temper Brittleness.—Whereas it is generally true that the higher the tempering temperature up to about 680° C. the tougher the steel, this is not invariably so. Certain steels, particularly those containing high proportions of chromium, manganese or phosphorus, become brittle if tempered within the range 400°–550° C. or if tempered at higher temperatures than these and slowly cooled; this is termed temper brittleness.

It may be avoided in steels that are susceptible by tempering at temperatures about 550° C. and quenching from the tempering temperature; additions of molybdenum markedly reduce the susceptibility of a steel to temper brittleness.

D. Surface Hardening

Service conditions frequently call for a steel with a hard, wear-resistant surface and yet for the component as a whole to be tough and resistant to shock and dynamic loading. Since both high hardness and toughness cannot be obtained from steel in a given condition, methods have been developed of imparting a hard surface or "case" without impairing the toughness of the main mass or "core." There are four principal methods.

1. Carburizing.—The component is made from a low-carbon steel, with or without alloying additions; the lower the carbon content the greater the toughness attainable. The component is then heated at about 900° C. in a carburizing atmosphere so that carbon diffuses into the steel; the depth of carbon penetration is dependent on the nature of the carburizing atmosphere, the temperature and the time of heating. After this treatment, the "case" usually contains about .8% by weight carbon, whereas the carbon content of the "core" is virtually unaltered. After carburizing, the "case" is hardened either by quenching the steel from the carburizing temperature or, better still, by heating the steel to about 760° C. and quenching. The structure of the "case" then becomes martensite of about 0.8% by weight carbon, *i.e.*, very hard, whereas the "core" is essentially ferrite and therefore tough.

2. Flame and Induction Hardening.—The component is made from a medium-carbon steel, with or without alloying additions, and is hardened and tempered in order to develop the optimum strength and toughness properties. The surface of the component is then rapidly heated to above the critical temperature range by means of either an oxyacetylene flame or high-frequency induction and, after a period varying from a second to a few minutes, the component is water-quenched. It is essential that only a thin skin or "case" is heated to above the Ac_1 temperature so that the properties of the "core" remain unaffected. On quenching the "case" becomes martensitic and hard.

3. Nitriding.—The two methods described above produce surfaces that are hard provided the temperatures developed during service do not exceed about 200° C.; at higher temperatures the martensitic "case" tempers and thereby becomes softer and less resistant to wear. Nitriding produces a thin but very hard "case" whose hardness is retained up to about 500° C. The components are made from steels of medium-carbon content and containing small amounts of aluminum, chromium and molybdenum. They are hardened and tempered at 550°–650° C. to develop the "core" properties and then heated for about 80 hours at about 500° C. in an atmosphere of ammonia. The ammonia partially dissociates into nitrogen and hydrogen; the nitrogen diffuses into the steel and, by forming compounds particularly with aluminum and chromium, gives rise to a very high hardness at and near the surface. The depth of the hard "case" increases with the duration of the nitriding treatment.

4. Hadfield's Manganese Steel.—The above three methods produce surface hardening only to a limited depth and so prolonged abrasion will wear away the "case." Castings made from steel containing about 14% by weight manganese and 1.4% by weight carbon, when quenched in oil from about 1,000° C., are extremely tough. Under the action of abrasive wear, the surface becomes extremely hard and this process of abrasion hardening is continuous so that in effect the "case" is never worn through (*see* Manganese Steel).

Other methods of surface hardening include "hard facing," *i.e.*, welding or brazing onto the steel component a very hard material like stellite, an alloy containing carbon, chromium, cobalt and tungsten, or tungsten carbide.

See also Surface Hardening. (D. L. T.)

XIV. SURVEY OF PRODUCTION

In tracing the development of the world's iron and steel output it is customary to commence with Great Britain, for although the output of pig iron in Great Britain in the second half of the 20th century was less than 10% of the world's total, and about the same in steel, nevertheless Great Britain was the birthplace of the modern iron and steel industry, and many of the developments connected with the industry originated there. Until 1871 the output of pig iron in Great Britain exceeded that of all other countries put together; in 1890 Great Britain was for the first time surpassed by the United States: in 1904 for the first time by Germany and in 1921—because of a coal stoppage—for the first time by France. In 1931 the output of the U.S.S.R. exceeded Great Britain for the first time.

According to Mushet, the output of pig iron in Great Britain in 1720 was 17,350 tons, but T. S. Ashton, in his *Iron and Steel in the Industrial Revolution*, gives reasons for thinking this too low, preferring the estimate of William Rea, an ironmaster of Monmouth, who put the output of pig iron at this period at about 25,000 tons per annum; he also points out that Scrivener's *History* (p. 57) wrongly gives 1740 as the date of Mushet's estimate, an error that has been followed by many later writers. The 25,000 tons produced in 1720 had risen to 68,300 tons by 1788; but, whereas the majority of the furnaces in 1720 had been charcoal, 55 in 1788 were coke furnaces. It is not possible to assess the effects of improvements in blast furnaces upon the demand for iron, nor of the demand for iron (created by engineering inventions) upon blast-furnace improvements; suffice it to say that by 1840 production of pig iron had risen to 1,396,000 tons; by 1860 to 3,890,000 tons; and by 1880 to 7,750,000 tons. Having nearly trebled in the 20 years between 1840 and 1860 and doubled between 1860 and 1880, the increase between 1880 and 1900 was no more than 16%. In the next several decades production of pig iron in Great Britain lagged, but by the second half of the 20th century it had increased to more than 10,000,000 tons.

It was not until the development of the pneumatic (Bessemer) converter in 1856 that the production of steel at relatively low prices was made possible. This was followed by the discovery of the open-hearth process by Siemens Brothers in 1864–67. Between 1877 and 1883 another obstacle to low-cost production of high-grade steel was removed through the perfection by Thomas and Gilchrest of a technique for removing phosphorus from steel during the processing period. The influence of these improvements on steel production is indicated by the rapid expansion of output in Great Britain. From 220,000 tons in 1870, it had grown to 4,900,000 tons by 1900 and by 1920 it had almost doubled again. Shortly after World War II, steel production was around 15,000,000 tons a year, or three times larger than at the beginning of the 20th century, and by 1960 it had reached almost 25,000,000 tons.

It is impossible to trace, even in this broad outline, the progress of development in the other iron and steel producing countries. In all cases, except where the industry is of comparatively late growth, iron was first smelted with charcoal, and coke but slowly won its way; *e.g.*, mineral fuel was first used in France in 1782, but by 1819 only two furnaces out of a total of 350 were using coke (*Memoirs of the Geological Survey of Great Britain*, vol. i, pt. 1, 1856, quoted by Ashton): but in all countries the great bulk of the steel output is made by the open-hearth process, which, after its discovery, rapidly supplanted the pneumatic converter process because of its economy and regularity of operation.

In 1880 open-hearth production in Great Britain accounted for about 20% of the total output, but by the second half of the 20th century it was almost 100%.

1. Pig Iron.—It will be seen from Table VI that in the 100 years ended in 1910, the average increase in world production of pig iron in any decade was 60%, while because of the dislocation caused by World War I, a loss of 3% was experienced in the ten years ended in 1920. However, in the decade ended in 1930,

the upward trend was resumed with increases of 26% and 29% each in the next two decades. A contributory cause of the slow growth after 1910 was that following World War I a greater proportion of steel scrap was used in steelmaking. Pig iron production, however, exceeded 100,000,000 tons in 1940 and reached an all-time peak during World War II (115,900,000 tons in 1943), after which it declined, as it had after World War I, and again increased, exceeding 200,000,000 tons by 1955 and 250,000,000 tons by 1960.

2. Steel.—Although output of pig iron in Great Britain reached a record of more than 10,260,000 tons in 1913 and never recovered completely from its subsequent decline, output of steel surpassed the production of pig iron frequently and by wide margins. By 1950 output of steel was nearly twice as large as in 1913. This high postwar level made Great Britain the first country among major world producers to exceed its highest annual output of the

TABLE VI.—*World Output of Pig Iron at the End of Each Decade, 1820 to 1920 and Certain Years From 1920 to 1960*

Year	Output (tons)	Year	Output (tons)
1820	1,000,000	1925	75,690,000
1830	1,800,000	1929	97,410,000
1840	2,700,000	1930	79,240,000
1850	4,700,000	1935	73,130,000
1860	7,220,000	1940	102,400,000
1870	11,840,000	1943	115,900,000*
1880	18,160,000	1945	79,300,000
1890	26,750,000	1950	134,000,000
1900	39,810,000	1955	212,200,000
1910	64,760,000	1960	260,000,000†
1920	62,850,000		

*U.S. Bureau of Mines, *Minerals Yearbook*. †Estimate.

war period. Production in the United States, after a severe slump in the decade prior to World War II, climbed swiftly to new heights during the war, exceeding 100,000,000 tons in the 1950s. Near the end of the war and immediately following, with output greatly reduced in most of Europe, the United States was called on to produce more than half the world's annual output of steel.

At the end of the war, world production of both pig iron and steel slumped from the record levels that had been attained. By the 1950s, however, production had recovered, exceeding prewar levels.

3. Iron and Steel Exports.—Annual exports of iron and steel from Great Britain and Belgium-Luxembourg shortly after World War II showed little change from the exports immediately preceding the war. Exports from the United States were several times larger than prior to the war. After World War II, during which the great bulk of iron and steel produced was immediately consumed, it was clear that the potential demand for iron and steel was considerable, but in the early postwar years most countries were too impoverished to make that demand effective, while most belligerent countries who before the war supplied capital for development were no longer able to do so on the same scale.

After World War I, France acquired Alsace and Lorraine from Germany. French production of iron and steel was greatly increased, leading to stronger competition in Europe. The German iron and steel industry, in second place among world producers between the two wars, underwent violent changes in the two wars. Recovery in the German Federal Republic (West Germany) was rapid and that country regained third place before 1960.

The increase in production in the U.S.S.R. of both pig iron and steel after 1925 had probably never been equaled. In 1925 output of pig iron was 1,300,000 tons, while in 1939 it was 15,000,000 tons, an increase of more than 1,100%. Steel production in 1925 amounted to 1,840,000 tons, but by 1939 it had expanded to nearly 23,000,000 tons, a gain of more than 1,200%. Thus, in 14 years the U.S.S.R. rose from sixth in importance among world producers to a position of nearly a tie for second place behind the United States. After World War II, production was increased progressively, exceeding Germany's prewar totals and placing the U.S.S.R. firmly in second place.

4. U.S. Production.—The output of pig iron in the United States, the world's largest producer since 1897, was 30,966,000 tons in 1913 and of steel ingots 31,301,000 tons. The enormous contracts for munitions, machine tools, etc., placed by the Allies during World War I, as well as the demands for equipping its own army, necessitated the extension of existing iron and steel plants and the erection of new ones. After the war, the great increase in capacity was absorbed by the growing internal demand and by 1937 output of pig iron was 37,130,000 tons and of steel 50,570,000 tons. These tonnages, somewhat less than in 1929, but the highest in the 1930s, were far surpassed during World War II and the postwar years. Continued expansion after that war placed steel capacity in the United States four times larger than at the beginning of the century.

With the development of alloy steels, which greatly widened the field of steel consumption, together with such refinements in production as the continuous sheet and strip mill which acted to lower greatly the cost of steel, the saturation point of steel consumption seemed as far away at mid-20th century as it was when the pneumatic converter was invented. However, plastics, and new processes for producing and fabricating such nonferrous metals as aluminum, magnesium, copper and zinc alloy die castings, constituted a challenge to the steel industry's position. Yet, on the other hand, steel had supplanted wood on a large scale for such applications as small home building, interior constructions, etc., which might counterbalance the effects of the greater use of plastics, etc. It might be reasonably assumed that the low cost of steel would for a long time support its position as the basic material of the modern world. This position apparently was more assured with huge new iron mining developments following World War II.

BIBLIOGRAPHY.—The fullest account of U.S. practice is contained in J. M. Camp and C. B. Francis, *The Making, Shaping and Treating of Steel*, 7th ed. (1958); for British and continental practice *see* L. Aitchison and W. I. Pumphrey, *Engineering Steels* (1953); H. P. Tiemann, *Iron and Steel* (1933), a pocket dictionary of terms and a brief encyclopaedia of the whole subject; American Society for Metals, *Metals Handbook*, 7th ed. (1948) and supplements (1954, 1955). Carl H. Samans, *Engineering Metals and Their Alloys* (1949); J. H. G. Monypenny, *Stainless Iron and Steel*, 2 vol. (1951); Academy of Sciences, U.S.S.R., *The Iron Ore Base of the U.S.S.R.*, ed. by I. P. Bardin (1957). Some fine textbooks cover only portions of the subject, such as Robert Forsythe, *The Blast Furnace and the Manufacture of Pig Iron* (1922); Walter Lister, *Practical Steelmaking* (1929); A. W. and Harry Brearley, *Ingots and Ingot Moulds* (1919); D. K. Bullens, *Steel and Its Heat Treatment*, 3 vol. (1948); Z. Jeffries and R. S. Archer, *The Science of Metals* (1939). Professional societies which devote much attention to the manufacture of iron and steel, and whose journals contain accounts and symposiums on the current state of the art are: (British) Iron and Steel Institute, American Iron and Steel Institute, American Society for Metals, the Iron and Steel Division of the American Institute of Mining, Metallurgical and Petroleum Engineers and the Society of Automotive Engineers. Leading journals of the trade are *The Iron Age; Steel; Metal Progress; Iron and Coal Trades Review; Stahl und Eisen;* and *Stal in English*. For current production statistics *see* the *Britannica Book of the Year*.

(E. E. T.; R. E. GE.)

IRONBARK, the name applied to certain species of *Eucalyptus* (*q.v.*) in Australia, from the hardness of the bark.

IRONCLAD, a naval term that came into use in the middle of the 19th century to denote a warship whose hull was protected by iron plates. Most of the earliest ironclads carried iron plates about 4½-in. thick, mounted on either a wooden hull or an iron hull. French and British ironclad floating batteries proved their value in the Crimean War (1854–56) and led the French to build the "Gloire," the first seagoing ironclad in 1859 and the British to build the "Warrior" in 1861. The first duel between ironclads occurred during the American Civil War (*see* "MONITOR" AND "MERRIMACK," BATTLE OF) and attracted world-wide attention. Before the end of the century iron plates gave way to steel and the term "ironclad" gave way to "battleship" (*q.v.*).

IRON CURTAIN, a term that came into popular use after World War II to denote the Soviet Union's efforts to seal off itself and its eastern European satellites from normal contacts with western Europe and other noncommunist areas. The term was used by Winston Churchill, Britain's wartime prime minister, in an address at Westminster college, Fulton, Mo., on March 5, 1946, when he declared that the U.S.S.R. had rung down an "iron curtain" across eastern Europe. The term so aptly described the conditions that existed after World War II, when the wartime

Allies split apart in an atmosphere of mutual distrust, that it soon gained widespread currency. When the People's Republic of China adopted a similar policy of exclusiveness in 1949 the term "bamboo curtain" was used to distinguish the Chinese policy from its Soviet counterpart. *See* EUROPE: *History: Communism and Europe.*

IRON GATE (EISERN TOR): *see* DANUBE.

IRON MASK. The identity of "the Man in the Iron Mask"—in fact a man in a velvet mask—remains one of the most famous enigmas of French history. During the latter decades of Louis XIV's reign this political prisoner was kept in captivity first at Pinerolo (Pignerol) in Piedmont, Italy, later in the fortress in the Îles Ste. Marguerite and finally in the Bastille, in Paris, where he arrived on Sept. 18, 1698, and where he died on Nov. 19, 1703. He was buried in the church of St. Paul (the parish church for the Bastille) and entered in its register under the name "Marchioly." Mystery and legend surrounded this man even in his lifetime: his jailer, the sieur de Saint-Mars (Bénigne d'Auvergne), a faithful servant of the marquis de Louvois, himself spoke of the "fairy tales" which were circulating on the subject. Many solutions to this mystery, some fantastic, have been attempted.

During the 18th century various suggestions as to the man's identity were made: in 1711, an English nobleman; in 1745, Louis de Bourbon, comte de Vermandois, a son of Louis XIV and Louise de La Vallière; between 1738 and 1771, an elder half brother of Louis XIV (Voltaire gradually launched this unlikely solution, which was later taken up by Alexandre Dumas in *Dix ans plus tard, ou le vicomte de Bragelonne,* translated into English as *The Man in the Iron Mask,* and it was Voltaire who first wrote of "a mask with springs of steel," instead of a simple velvet one); in 1768, François de Vendôme, duc de Beaufort (*q.v.*); in 1768 likewise, James, duke of Monmouth (*q.v.*); in 1770, Ercole Matthioli (*see* below); in 1789, Louis XIV's finance minister, Nicolas Fouquet (*q.v.*); and in 1790, the Armenian patriarch Avedick, kidnapped from Constantinople by the French ambassador Charles de Ferriol. The 19th- and 20th-century solutions include Louis, chevalier de Rohan (1869); an adventurer and spy from Lorraine called Oldendorf proposed by A. Jung (1872); Molière, imprisoned by the Jesuits in revenge for *Tartuffe* (1883); Eustache Dauger (*see* below; first proposed by J. Lair in 1890); Gen. V. L. de Bullonde, arrested by Louis XIV for his retreat from the siege of Cuneo (1893); a Jacobin monk (1893); the *abbé* Pregnani, involved in the religious affairs of Charles II of England (1908); Eustache d'Oger de Cavoye, a dissolute young man of the period 1659–65 (1932); and Marc de Jarrige de la Morelhie, the son-in-law of the physician who supposedly proved Louis XIII's impotence at his autopsy (1934). Consultation of the authentic documents in the archives of the Bastille, of the French foreign office and of the ministry of war shows that only two of these hypotheses are tenable: Matthioli and Eustache Dauger.

Matthioli, a minister of Ferdinand Charles, duke of Mantua, had been entrusted with the secret negotiation of the treaty of 1678 whereby the impoverished duke was to deliver the stronghold of Casale over to France in return for 100,000 *écus;* but as soon as the agreement was signed, he nullified its effect by betraying the secret to several foreign courts. Furious at having been tricked, Louis XIV had him quietly abducted by Gen. N. Catinat and imprisoned at Pinerolo (1679). It is generally agreed, however, that Matthioli died in the Îles Ste. Marguerite in April 1694, and that the prisoner in the mask was Eustache Dauger.

The correspondence of Louvois indicates that Dauger was only a valet who was arrested on his orders for an unknown reason near Dunkerque in July 1669. At Pinerolo this Dauger served as Fouquet's valet, and after Fouquet's death (1680) he was kept in close confinement with another man who had also served Fouquet. From Pinerolo, Saint-Mars took him in 1681 to Exiles (whereas Matthioli then stayed behind), before moving to the Îles in 1687. It is possible that both Louvois and Colbert, enemies of Fouquet, wanted these prisoners kept in custody, lest they should divulge secrets that Fouquet could have told them.

Perhaps this consideration, rather more than his original crime, explains the absolute secrecy to which Dauger was condemned and the precaution of the mask. Numerous conjectures have been made about his first crime, which no documents mention. His arrest at Dunkerque in the summer of 1669 raises the possibility that he may have been concerned in the secret negotiations which led to the treaty of Dover (*q.v.*) between England and France. On the other hand, some think that Dauger had been involved in a scandal incriminating some great family. If it be granted that Matthioli died in 1694, the enigma can be regarded as solved insofar as the identity of the prisoner is concerned; the reason for his arrest and imprisonment for 34 years remains a mystery.

IRONMONGERY: *see* HARDWARE.

IRON MOUNTAIN, a city of Michigan, U.S., the seat of Dickinson county, adjoining the city of Kingsford, is just north of the Menominee river, which separates the upper peninsula of Michigan from Wisconsin. Iron Mountain, the commercial centre of the county, was settled as a mining community in 1879 and incorporated in 1889. It was so named because of its proximity to a bluff heavily stratified with iron ore. Mining continued to be important in the economy until the 1930s, when ore deposits were virtually exhausted. Kingsford was incorporated as a village in 1925 as an outgrowth of Ford Motor company operations; it was incorporated as a city in 1947.

The Iron Mountain-Kingsford area is studded with small plants that manufacture metal parts; electric controls; chemicals; furniture, paper and other wood products; and wearing apparel. A large ski slide, on which the world's foremost skiers have jumped distances over 300 ft., is but one of many tourist attractions. Iron Mountain is also the home of a large veterans' administration hospital. For comparative population figures for both cities *see* table in MICHIGAN: *Population.* (R. F. O'D.)

IRONSTONE, referring in the past to certain iron carbonate deposits, notably the clay ironstone concretions, this term later came to mean an iron-bearing formation. Iron, the fourth most abundant element in the earth's crust, occurs in nearly all rocks, the iron content varying from nil to several per cent. In some sedimentary strata it exceeds 15%; such rocks are called an iron-bearing formation, an iron formation or ironstone.

Ironstones are sedimentary deposits of varied composition. They may be iron sulfides (pyrite), iron carbonate (siderite), iron silicates (chamoisite, greenalite, etc.) and iron oxides (hematite, etc.). These materials are generally mixed with silica (commonly chert), clay, etc., and form strata of ironstone.

Among the best-known ironstones are those of Pre-Cambrian Age in the Lake Superior region. These average 25% iron but in places are enriched and constitute iron ores. Since their discovery they have yielded about 2,000,000,000 tons of ore (50% or more iron). Silurian ferric oxide ironstones occur in the Appalachian region and are mined in the Birmingham district of Alabama.

Ironstones were precipitated in marine waters, in lakes and in swamps ("bog ore"). Their mineralogy is dependent on the oxidizing potential of the environment.

See F. J. Pettijohn, *Sedimentary Rocks,* pp. 449–467 (1957). (F. J. P.)

IRONWOOD, a name applied to many hard and heavy woods or to the trees that produce them. Certain ironwoods, e.g., *Krugiodendron, Olneya,* sink in water. Many are very difficult to work and so require the use of machine tools rather than hand labour. Among the ironwoods of the United States, the most widely distributed are *Ostrya virginiana,* also called hop hornbeam, and *Carpinus caroliniana,* also called hornbeam and blue beech (*see* HORNBEAM). These trees, members of the birch family, range over eastern United States and adjacent Canada. Their wood is used for fuel, levers, fence posts and tool handles. Ironwoods of more southerly distribution in North America include desert ironwood (*Olneya tesota*) of southwestern United States and adjacent Mexico. Its wood makes excellent fuel and is used for novelties. Black ironwood (*Krugiodendron ferreum*), one of the world's densest woods (specific gravity 1.34–1.42), is native to southeastern United States, southern Mexico, British

Honduras and the West Indies. Ironwoods of somewhat similar distribution are those derived from *Cyrilla racemiflora*, also called leatherwood; from species of *Jacquinia*, also called joewood; and from *Exothea paniculata*, known in Florida as butterbough or inkwood. Catalina ironwood in the California coastal islands is *Lyonothamnus floribundus*. *Reynosia septentrionalis*, found in Florida and the Bahamas, is known as red ironwood. The durable wood of *Hypelate trifoliata*, white ironwood, is used in Florida for fence posts.

Woods known as ironwood in Jamaica include *Sloanea jamaicensis* and *Turpinia paniculata*, neither of commercial importance. The useful timber of *Dialium guianense* is called ironwood in British Honduras. Asiatic ironwoods include *Xylia dolabriformis* and *Mesua ferrea*, valuable timber trees. Among Australian trees that may be known as ironwood are scrub ironwood (*Myrtus acmenoides*); lemon ironwood (*Backhousia citriodora*); giant ironwood (*Syncarpia subargentea*); species of *Geijera*, also called axe-breaker; and *Notelaea ligustrina*, also called silkwood. Uganda ironwood (*Cynometra alexandri*), of Uganda and the Congo, and black ironwood (*Olea laurifolia*), of South Africa, are used for heavy construction. One of the most durable timbers of west tropical Africa is ekki, red or west African ironwood (*Lophira procera* var. *alata*). (J. W. Tt.)

IRONWORK, in this article refers to all objects made in iron with the exception of armour and weapons (for which *see* Armour, Body; Helmet; Sword; etc.), but special emphasis has been given to the use of iron in the exterior or interior decoration of buildings. This article begins with a brief over-all view of the history of ironwork, followed by surveys of the history of ironwork in various countries: India and southeast Asia, China, Japan, the major countries of Europe, and the United States. The article concludes with a section on the techniques of wrought iron and cast iron. *See* also Metalwork, Decorative.

HISTORY

The earliest recorded iron artifacts are some beads, dating from about 3500 B.C. or earlier, found at Gerzah in Egypt. They are made from meteoric iron, as are a number of other objects of only slightly later date that have been found both in Egypt and Mesopotamia. The earliest known examples of the use of smelted iron are the fragments of a dagger blade in a bronze hilt, dating from the 28th century B.C., found at Tell Asmar in Mesopotamia and some pieces of iron from Tell Chagar Bazar, in the same area, of approximately the same date. There is, however, no evidence of any extensive use of iron in either Egypt or Mesopotamia before the end of the second millennium B.C. In Asia Minor, on the other hand, iron was probably used regularly from at least as early as 2000 B.C. and it seems likely that the first true iron industry was established there in the second half of the second millennium B.C.

From the ancient east the knowledge of ironworking was transmitted to Greece and the Aegean, probably at the beginning of the first millennium B.C., whence it spread gradually to the rest of Europe. By the 6th century B.C. it had been widely disseminated over central and western Europe.

Iron was at first apparently regarded as a precious, semimagical material, presumably because of its rarity and its connection with meteorites. But once it had become common, as a result of the spread of knowledge of the technique of smelting ore, it seems to have been used, at least in Europe, almost exclusively for objects of utility. A few Belgic firedogs and at least one amphora stand skilfully forged in iron with decorative terminals in the form of animal heads are known, but the practice of forging iron into decorative shapes does not seem to have become general until the middle ages.

A few cast-iron objects dating from classical times have been found in Europe. The extreme rarity of these, however, suggests that they were only produced experimentally. The earliest known evidence for the general use of cast iron comes from China (*see* below) and it does not seem to have been produced regularly in Europe before the 15th century. From the second half of that century onward it was used widely for the manufacture of ordnance, utensils, firebacks and stove plates, the last two usually decorated with designs in relief. The development in Britain during the 18th century of the puddling process and the cupola furnace made possible the production of larger quantities of better-quality cast iron and during the second half of the century it was used increasingly in architectural work, notably for decorative railings, grates, etc. By the early 19th century cast iron had become the most widely used of all metals, remaining so until the second quarter of the 20th century. (C. Bl.)

Asia

India and Southeast Asia.—The manufacture of iron and steel by primitive small-scale methods has survived in southern India and Ceylon to the present day. The iron is smelted directly from the ore, and true carbon steel of high quality is made by melting the iron with a small proportion of green wood in a clay crucible heated to a high temperature. The slag heaps of ancient furnaces are common and the processes have probably been in use for more than 2,000 years, but it is unknown whether they are of indigenous invention or acquired. In southern India iron immediately succeeded stone as a material for tools and weapons, and prehistoric iron weapons began to come into use about 500 B.C. Alexander received a gift of Indian steel from the Punjab chiefs; steel dating from the 2nd century B.C. has been found at Besnagar and in Ceylon, and tempered steel is referred to in the *Ummagga Jataka*. Buddhist begging bowls are generally made of iron. The wrought-iron pillar of Delhi, set up about A.D. 400 by Kumaragupta I in honour of his father, is over 23 ft. in height and weighs more than 6 tons; it demonstrates the abilities of Indian metalworkers in handling large masses of material, for not until the latter part of the 19th century could anything of the same kind have been made in Europe. There are other large iron pillars at Dhar and at Mt. Abu. (*See* also Indian Art; Indonesian Archaeology and Art.) (A. K. C.)

China.—Iron began to take its place in the brilliant Bronze Age culture of China during the Ch'in dynasty (221–207 B.C.) and the early Han dynasty (202 B.C.–A.D. 221). By the end of the 2nd century A.D. bronze weapons had been almost completely supplanted, while iron had been generally substituted for bronze in common use in utensils and vessels of various kinds, tools, chariot fittings and even small pieces of sculpture. These were commonly cast in sand molds, were patterned after bronze prototypes and were typical in style and decoration of the Han period.

From the 9th century iron increasingly took the place of bronze in China as a material for sculpture, especially in the north and under the Sung dynasty. The few extant examples from the 11th century and later show work done on a larger scale and in coarser technique than the bronzes, though the modeling is usually more naturalistic.

Several iron pagodas, ranging in size from miniature models to towers 30 or more metres in height, and dating from the 10th to the 14th century, give further evidence of the dexterity of the Chinese iron caster. These imitate in detail both the structural and decorative effects of the more common tile-roofed brick pagodas. Iron for temple furniture has long been in use, and a large number of the braziers, censers, caldrons and bells found today in the temples are of iron.

In China in the 17th century the iron picture was developed, the craftsmen seeking to reproduce in permanent form through the medium of wrought iron the effects of the popular ink sketches of the master painters. When completed, these pictorial compositions were mounted in windows, in lanterns or in frames as pictures. When in the latter form a paper or silk background often bore the signature and seal of the maker, heightening the resemblance to a painting. The craft flourished in Anhwei province and is still practised, though with less patience and fineness than formerly.

Japan.—The Iron Age in Japan is supposed to have begun in the 2nd century B.C., though the chief early remains are weapons from the dolmens of the 2nd to the 8th centuries A.D. The Japanese iron founder attained a considerable skill at an early date and acquired a social position which was never attained by the bronze caster, or by the ironworkers in China where the Bronze Age tra-

dition was much stronger. It is apparent that iron was used in China chiefly as a substitute or imitative medium, worked often with great skill but with little artistic invention. In Japan, however, the ironworker developed a distinctive and original means of expression and high artistic attainment in furniture for the sword. With the rise of feudalism and the establishment of the samurai class after the wars of the 12th century, the equipment of the warriors became an object for the efforts of the artist.

At first these efforts were devoted to the embellishment of defensive armour, but from the 15th century the sword became the centre of attention. The blade is not properly part of the subject of this article, but in the mountings, especially the guards (tsuba), is found exquisite artistry expressed chiefly in iron. A remarkably soft and pure variety of the metal especially free from sulfur was employed. It was worked by casting, hammering and chiseling; and innumerable surface effects were obtained by tooling, inlaying, incrustation, combination with other metals and patination by various, usually secret, processes. Simple conventional patterns, crests and pictorial designs were the bases for the decoration. As these were often furnished by painters or designers the criterion of connoisseurship in Japan is the unsurpassed technical quality of the handling of the iron itself. With the promulgation of the edict of 1876, prohibiting the wearing of swords, this art came to an end, but the skill of the Japanese ironworker may still be noted in numerous small decorative objects. (B. Mar.)

Europe

Belgium and Holland.—The ironwork of these two small countries prior to the 15th century was in no way inferior to that produced elsewhere. Yet so few pieces remain that the significance of craftsmen of the Low Countries has often been underestimated. During the 15th century design and craftsmen from the Low Countries began to make their influence evident across the channel in England. The outstanding craftsmen were of the Massys family of Louvain. Representative examples of this period are in the great church at Breda; the treasury door of the cathedral and some presses in the church of St. James, both at Liége; and hinges of the church of Notre Dame, Hal. The beautiful spires of Bruges, Ghent and Antwerp should also be mentioned.

During the first half of the 16th century, before the Spanish occupation, there were diversified forms of ironwork, such as protective grilles for doors, windows and chapels, often in fleur-de-lis patterns; window gratings of vertical bars, frequently octagonal in section; and interlacing bars, producing rectangular or lozenge-shaped patterns. Only a few examples still exist; *e.g.*, some lunettes in the *hôtel de ville* of Brussels; a tabernacle grille from the chapel of the counts of Flanders and a window grille from St. Bavon, both from Ghent and now in the Victoria and Albert museum, London; and hinges at the *hôtels de ville* of Bruges and Ypres. Few Renaissance screens have survived.

During the second half of the 16th century the cruelty of the duke of Alba and his 20,000 troops, together with the threat of the Inquisition, drove hundreds of artisans to England. After the Spanish domination there was little indigenous design in Holland and Belgium, and such ironwork as was produced fell under the spell of French importations. (G. K. G.)

2. England.—The initial use of wrought iron was purely protective because violent attacks were frequent, and doors had to be strengthened with massive ironwork inside and out. Window openings, especially those of the treasuries of mansions and cathedrals, were for similar reasons filled with strong interlacing bars of solid iron; a good example remains at Canterbury cathedral. When in course of time the need for protective barriers ended, there came greater freedom of work and a definite ornamentation. Throughout England, medieval church doors are found with massive iron hinges, the bands worked in rich ornamental designs of scrollwork, varying from the plain hinge band with crescent, to the most elaborate filling of the door. Examples exist at Skipwith and Stillingfleet in Yorkshire, many in the eastern counties, others in Gloucester, Somerset and the west Midlands. The next important application of ironwork came with the erection of the great cathedrals and churches, whose shrines and treasures demanded protection. Winchester cathedral possesses the remains of one screen with a symmetrical arrangement of scrollwork. The grille above the tomb of Queen Eleanor at Westminster abbey recalls Thomas de Leghtone, a master craftsman in iron who had succeeded another great smith, Henry of Lewes. Tombs were enclosed within railings of vertical bars with ornamental finials at intervals, such as that of the Black Prince at Canterbury. A new development appeared in the early years of the 15th century when the smith, working in cold iron, attempted to reproduce Gothic stone tracery in metal. This work was more like that of a woodworker than of a smith, often consisting of small pieces of iron chiseled and riveted, and fixed on a background of sheet iron. Many small objects such as door knockers, handles and escutcheons are to be found executed in the same manner. A typical monumental example is in Henry V's chantry at Westminster abbey, but the most magnificent is the great grille at St. George's chapel, Windsor, made to protect the tomb of Edward IV. It was executed by an Englishman, John Tresilian.

Smithing declined in England during the 16th century. The development of the art during the Renaissance period was very uneven in the various countries of Europe. In England the smith fell behind and seemed to have lost interest, producing no very great or important work. He continued to make iron railings, balconies and small objects for architectural application, such as hinges, latches, locks and weathercocks. But toward the end of the 17th century, there was a growing interest in beautifying houses and laying out gardens and squares with a commensurate demand for balconies, staircases and garden gates. The man to whom the credit is usually given for the revival of ironwork in England was Jean Tijou, a Frenchman who, together with many of his Protestant fellow craftsmen, had been forced to leave his country owing to the revocation of the Edict of Nantes in 1685. After some years in the Netherlands he went to England in 1689 where he enjoyed the patronage and favour of William III. His most important works for his royal patron are to be seen in the immense mass of screens and gates with which he embellished Hampton Court palace. He also executed work at Burleigh house, Stamford. Probably by the queen's wish he was associated with Sir Christopher Wren, then engaged on the rebuilding of St. Paul's cathedral. Wren apparently did not particularly like ironwork and probably exercised some restraint on Tijou, with the result that his work at St. Paul's is more dignified and freer from appendages than that at Hampton Court.

A great amount of fine ironwork of the 18th century may be studied in London in the form of gates, railings, lamp holders, door brackets, balconies, staircases; in almost every suburb may be seen gates and brackets. The precincts of the colleges of Oxford and Cambridge, as well as almost every old town in England, furnish a variety of handsome work. Throughout the 18th century the smith was a busy man; the general tendency of his work, unaffected by the rococo movement on the continent, was toward a less ornate but more characteristically English style, Perpendicular, severe, lofty and commanding, as contrasted with Tijou's French love of richness and mass of details.

At the end of the 18th century the work of the architect brothers Adam shows a departure from true smithing; its slender delicate bars are enriched with rosettes, anthemion and other ornament in brass or lead. The effect is pleasing and harmonizes with the architecture with which it is incorporated.

During the first half of the 19th century the art of the smith was largely eclipsed by that of the iron caster. But under the stimulus of the Victorian gothic revival and later of the *art nouveau* movement there was a renewal of interest in the decorative use of wrought iron and much excellent work was produced.

France.—Medieval door-hinge ornaments were not basically different from those in England, and beautiful work is found on church doors, especially in central and northern France. It reaches a height of greater elaboration and magnificence than in England, the culminating example being the west doors of Notre Dame, Paris, the ironwork of which is so wonderful that it was attributed to superhuman authorship. Grilles at Troyes and Rouen reveal a high standard of excellence. Working the iron cold, and employ-

ing methods associated with carpentry, was immensely popular; it was applied to small objects such as door handles, knockers, ambry doors, and above all to locks. These exhibit an amazing amount of detail and a remarkable delicacy of finish.

The Gothic tradition survived in France until well into the 16th century, and was marked by the production of work of the highest skill, largely in the form of locks, knockers and caskets of chiseled iron. The introduction of the Renaissance style did not radically alter the direction of the smith's art—a strange fact when it is remembered how Germany and Spain were fabricating works of enormous size and magnificence in wrought iron. France, like England at that time, was content to make door furniture, in the form of locks, keys, bolts, escutcheons and the like, but did little ironwork of any great size. A school of locksmiths came into being under Francis I and Henry II, working from designs by Androuet du Cerceau in the 16th century, and Mathurin Jousse and Antoine Jacquard in the 17th. The bows and wards of keys were of unusually intricate design, and the locks of corresponding richness. Representative pieces may be seen at the Victoria and Albert museum, London. Among them is the famous Strozzi key, said to have been made for the apartments of Henry III, the bow of which takes the favoured form of two grotesque figures back to back. But as far as architectural ironwork was concerned, France remained almost at a standstill until the accession of Louis XIII in 1610. Under that monarch, a worker at the forge himself, came a great revival. It seemed to be uninfluenced from without, at first weak, as if feeling its way, but by the end of the 17th century it had attained a marvelous pitch of perfection. It proved to be the beginning of a new movement, the force of which made itself felt in the adjoining countries and inspired ironworkers with new energy. From the accession of Louis XIV the French ironworkers must be acknowledged as the cleverest in Europe, combining as they did good and fitting design with masterly execution. Their designs were often very daring, exploiting all the latent and previously unexplored possibilities of iron. They recognized its great adaptability and took every advantage of it, at the same time being conscious of its limitations. Their forms of expression were endless.

Screens and gates were needed for parks, gardens and avenues, staircases for mansions and palaces, screens for churches and cathedrals. Among celebrated designers were Jean Lepautre, Daniel Marot and Jean Bérain. Earlier work had been of a simple character, balconies for instance, being in the form of a succession of balusters, but as the smith became more versatile and imaginative, they took the form of panels of flowing curved scrolls, rendered with a freedom never attained before, while constructive strength was observed and symmetry maintained. Enrichments were usually attached in hammered sheet iron. These may be considered the distinguishing features of Louis XIV work such as that at St. Cloud, Chantilly, Fontainebleau and elsewhere. But under Louis XIV all previous efforts were surpassed in the work for his palace at Versailles.

The art of ironwork received a further impetus by the introduction of the rococo style. The movement initiated in 1723 was due principally to the imagination of two artists, Just Aurèle Meissonier, architect, and Gilles Oppenordt. There was a balanced asymmetry in the design, and fantastic curves with a luxury of applied ornamentation. To the French smith it furnished the opportunity for a yet greater display of his skill. He was clever enough to secure a feeling of stability in his work by counterbalancing swirling masses of ornament with straight constructional lines; he knew how to introduce an iron screen of rococo style into a Gothic church or cathedral without giving offense to the eye or arousing any uncomfortable feeling of incongruity. With astonishing manipulative power he worked as if the material under his hand were soft and pliable, rather than solid and unyielding iron.

BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM

FIG. 1.—IRONWORK RAILING FROM A BALCONY AT VERSAILLES: LATE 18TH CENTURY

Later in the 18th century ironwork took on a more classical appearance, owing to the general revival of interest in ancient art, and many Greek and Roman details were introduced into the ornamentation. The amount of work executed was prodigious, and its beauty and craftsmanship may be seen in most cities of France; *e.g.*, in Nancy.

Nearly all the adjacent countries were seized with the desire to imitate this French rococo style, England excepted.

Germany.—In the Romanesque period in Germany bronze was preferred to iron; the earliest examples of ironwork are later than those of France and England. The first iron grilles were imitations of French work, having C-scrolls filling spaces between vertical bars. Typical examples of door hinges prior to the 14th century were those at Kaisheim, St. Magnus church, Brunswick, and St. Elizabeth's church, Marburg (the latter having a curious cross in the middle). Throughout the Gothic period in Germany, the imitation of natural foliage was the basis of design.

There were no new marked developments in ironwork during the 14th century. Smiths confined their efforts mostly to hinges. Up to this period the vine had been the only motif for elaborate hinges, but flat, lozenge-shaped leaves were introduced, such as at Schloss Lahneck on the Rhine.

During the 15th century grilles became more popular. One of the best examples is the grille in the chapel of Bishop Ernst, Magdeburg cathedral (*c.* 1498), with elaborate Gothic tracery, nine columns and a cornice. In hinges the cinquefoil displaced the quatrefoil, as at Orb, Oppenheim and Magdeburg. The Erfurt cathedral was enriched with notable hinges having the vine pattern interpolated with rosettes and escutcheons of arms. Hinges for houses usually were the plain strap type, but when ornamented they consisted of superimposed layers of sheet iron. As in other parts of Europe at this time, pierced sheet iron was fashioned into tracery of a semiarchitectural nature, much like Gothic windows. Pierced ornament and twisted rods were often combined to form grilles, with their extremities beaten into complicated foliage forms.

During the Renaissance, ironwork in Germany was in use everywhere and for every purpose: for screens in churches, window grilles, stove guards, gates, fountain railings, well heads, grave crosses, door knockers, handles, locks, iron signs and small objects for domestic use. Smiths were their own designers, and more often than not planned intricate devices merely to show their skill in executing them. They set no limits to their problems, and so far as manipulative excellence went, they were the foremost nation of Europe. But clever as their workmanship undoubtedly was, their designs frequently showed a lack of stability and a tendency to run riot. Thus many of their most imposing works consist largely of filling panels with elaborate, interlacing scrollwork, and the sense of constructional and protective strength is missing.

An abundance of smiths' work is to be found in the southern parts of Germany. Iron bars, circular in section, were most frequently used, and the most common features are: interlacing bars, terminations of flowers with petals and twisted centres, foliage or human heads. All of these characteristics occur with almost monotonous repetition, witnessing to skill, but also lack of imagination and sense of design. The style may be studied in many German and Austrian cities; *i.e.*, Augsburg, Nürnberg, Frankfurt, Salzburg and Munich; the work at Innsbruck is also well known.

The German smith gave much attention to door knockers and handles, enclosing them in pierced and embossed escutcheons, as well as locks with very involved mechanism. German influence made itself strongly felt in Switzerland, Austria and Czechoslovakia.

The baroque and rococo periods are distinguished by a perfec-

tion of detail which exceeded that of German medieval or Renaissance ironwork. Smiths used wrought iron as though it were a plastic material, meant to be employed in extravagant forms wherever possible. Some examples are at Zwiefalten, Weingarten and Klosterneuburg. In the late 18th and early 19th centuries cast ironwork of outstanding quality was produced in Germany, notably at the Prussian royal foundry established in 1804.

Italy.—The few extant examples of ironwork in Italy prior to the 14th century indicate a wide appreciation of how the material could best be worked with only the tools of the smith. Some noteworthy examples are: chancel grille at left of nave, Orvieto cathedral (1337); grille around the Scaligeri tombs of Verona (*c.* 1340); grille at baptistery of Prato cathedral (1348); chancel screen in the sacristy chapel of Sta. Croce, Florence (1371); and the grille to the Capella degli Spagnoli, Sta. Maria Novella, Florence.

Until the 16th century Italian smiths respected the natural characteristics of wrought iron by relying almost entirely upon those forms which could be wrought with hammer and anvil. The grille was generally made by dividing it into regular panels with vertical and horizontal bars (sometimes triangular in section and enriched with dentils). Often the quatrefoil filled some or all of these panels; they were made in Tuscany from a pierced plate, and in Venice from separate scrolls collared together. A noted example is in the Palazzo della Signoria, Siena, crowned by a *repoussé* frieze, and surmounted by a cresting of flowers, spikes and some animal heads.

It might have been thought that in the fountainhead of the Renaissance, ironwork would have proceeded at the same pace and with the same brilliant success as architecture, sculpture, bronze casting and the other arts. Strangely enough, little use of it is found in connection with the fine buildings of the revival. Bronze was favoured, and what in other countries is found in iron, has its counterpart in Italy in bronze. As time went on the smiths grew less inclined for the more difficult processes of hammering and welding, and contented themselves ultimately with thin, ribbon iron, the various parts of which were fastened together by collars. Work of the later periods may be distinguished, apart from the design, by this feature, whereas the English and French smiths vigorously faced the hardest methods of work, and the German and Spanish smiths invented difficulties for the sheer pleasure of overcoming them.

FIG. 2.—VENETIAN GRILLE, 16TH CENTURY. IN THE VICTORIA AND ALBERT MUSEUM

Notable centres of artistic ironwork were Florence, Siena, Vicenza, Venice, Lucca and Rome, where important pieces may be found in the form of gates, balconies, screens, fanlights, well covers and a mass of objects for domestic use, such as bowl stands, brackets and candlesticks.

In screenwork the favourite motif was the quatrefoil, which is found with many variations ever since the 14th century. Early examples are strong and virile, later ones tend to weakness. The C-shaped scroll is used in many combinations. The churches and palaces of Venice contain many examples. Peculiar to Italy are the lanterns and banner holders such as may still be seen at Florence, Siena and elsewhere, and the rare gondola prows of Venice. Of the ironworkers of the early Renaissance the most famous was Niccolo Grosso of Florence, nicknamed "Il Caparra" because he gave no credit but insisted on money on account. He worked at the end of the 15th century. From his hand is the well-known lantern on the Strozzi palace in Florence, repeated with variations elsewhere in the same city. Siena can show other lanterns and banner holders attached to the facades of its palaces. Cressets are still to be seen at Lucca and a few other towns.

The decadence of 17th- and 18th-century ironwork paralleled that of architecture. Designs were borrowed directly from France and Germany. The metal was too often worked cold, using thin members, and the resulting construction was flimsy. Scrolls were often encased in thin, grasslike leaves. Conventional or naturalistic flowers were tacked on as seeming afterthoughts. Instead of using rods and bars, ribbonlike bands were used, with cast ornaments pinned on. Intersecting tracery was copied from Germany. The best examples of this period are confined to Venice and northern Italy, such as the screen in the south aisle chapel of S. Ambrogio, Milan; the chapel enclosure in S. Pietro, Mantua; and the screen in the Palazzo Capodilista, Padua.

Spain.—Prior to the 15th century Spanish ironwork was basically similar to that in France and England. The Spanish smith accepted the limitations imposed by anvil and ancillary tools, but he skilfully exploited to the limit all manner of variations; *e.g.*, twisting square rods, coiling flat bars into C-shaped scrolls of all sizes and devising imaginative crestings to surmount the top of church chapel screens or domestic window grilles. Many Moorish craftsmen of extraordinary ability were enticed to remain in Spain as the Moors were slowly pushed southward; the resultant blending of Gothic with Moorish resulted in the Mudéjar style.

Ironwork of the Renaissance period from about 1450 to 1525 reached a height of grandeur and magnificence attained in no other country. Of all the Spanish craftsmen the smiths were the busiest, especially during the 16th century. The particular manifestation of work in iron, which for more than a century towered above all the others, may be seen in the screens of monumental size (*rejas*) to be found in all the great cathedrals of Spain.

These immense structures, rising to 25 or 30 ft., show several horizontal bands or tiers of balusters, sometimes divided vertically by columns of hammered work and horizontally by friezes of hammered arabesque ornament. Usually such screens are surmounted by a cresting which is sometimes of simple ornament, but more often is a very elaborate design into which are introduced a large number of human figures. Shields of arms are freely incorporated, and the use of bright colour, silvering and gilding adds to their impressive beauty. The great balusters were always forged from the solid, and their presence in hundreds demonstrates the

extraordinary skill and power of the Spanish smith. The *reja* shut off the high altar of the church or cathedral from the nave, and a further opportunity came to the smith when the choir was moved from the transept, to west of the crossing. This necessitated a second screen to enclose the east end of the choir, and naturally this screen could be in no way inferior to that in front of the high altar. Thus in many cathedrals two of these monumental *rejas* are found facing one another. It was the smith's opportunity, and he availed himself to the full. Monumental *rejas* may be seen in all the large cathedrals of Spain—Barcelona, Saragossa, Toledo, Seville, Burgos, Granada, Córdoba and many others.

Ironwork on a smaller scale is found in gates, balconies and window screens; wrought-iron pulpits also exist. The panels of hammered and pierced iron, heightened with colours and gilding, were used in connection with domestic architecture; many doors were ornamented with elaborate nailheads or embossed studs.

(W. W. W.; G. K. G.)

United States

Early History.—The characteristics of the earliest ironwork in the various colonies naturally reflected those of the parent countries. The English were more sparing in its use in the New England colonies, than were the Germans in Pennsylvania or the French in Louisiana. In the 17th and 18th centuries ironwork was used mostly for such practical purposes as weather vanes, foot scrapers, strap hinges, latches, locks and particularly for the necessities and conveniences for fireplaces (firedogs, cranes, skewers, toasters, kettle warmers and spits). It was not until the late 18th century, when the threat of Indian raids and food shortages had waned, and the established communities enjoyed a sense of tranquility and prosperity, that smiths fashioned wrought iron into railings, fences, grilles, gates and balconies. Square or flat iron bars were generally used to produce designs that were usually light, airy and graceful, and rather in contrast to the contemporary European preference for sturdier forms.

The revolt against English political rule was reflected in the decline of English ironwork traditions, and in the steadily increased acceptance of the work by French and German craftsmen throughout all the 13 colonies.

Gradually ironwork designs tended to develop characteristics of an American or composite nature, as a logical consequence of the diverse origins of colonists and smiths. An innovation, which appeared toward the end of the 18th century, was the combination of structural wrought-iron rods or bars, with lead or cast-iron ornamental features. While the use of wrought iron declined during the 19th century, during its last quarter the use of cast-iron columns and panels for non-residential buildings increased. These designs, timid or bold, decorative or structural, engendered the prototypes of commercial buildings for the ensuing decades.

Unfortunately the life of structures in U.S. cities has been short. There are few examples of 18th- or early 19th-century ironwork extant in New York, not many more in Boston, some in Philadelphia, but more in and near Washington, D.C., such as the excellent balconies and railings at the Octagon (headquarters of the American Institute of Architects). Charleston, S.C., has a rich legacy in gates, notably those at numbers 12, 23 and 36 Legare street, 63 Meeting street, and the unusually beautiful pair at St. Michael's church. The latter is credited to Justi, who came to Charleston from Germany in 1820. Two other gifted German artisans who settled in Charleston were Werner in 1828, and Julius Ortman in 1847.

New Orleans has more ironwork than other U.S. cities, thanks to a group of citizens dedicated to the preservation of the old French Quarter. Its earliest ironwork was forged by Spanish and French smiths. Unfortunately fires, rust and remodeling have so taken toll of the Spanish ironwork, that almost the only remaining example of importance is the gateway of the Cabildo (town hall). It has moldings beaten from solid bars, like many of the old *rejas* in Spanish cathedrals. After the Louisiana purchase in 1803, the influx of ironworkers from northern states brought about a broadening of influences that are apparent in designs and techniques. Ironwork of New Orleans can be roughly divided into three periods: (1) forged wrought iron by French and Spanish artisans with strongly marked European characteristics; (2) a transitional period with wrought-iron structural members embellished with cast-iron ornaments in the Directoire and Empire styles of France, plus some U.S. innovations; and (3) entire grilles, screens and treillage made entirely of cast iron. No other city in the U.S. has two- and even three-story iron porches and balconies which can compare with those of New Orleans. Some of these lacy structures were built above the sidewalks, such as those on St. Peter street. Balconies sometimes not only extended across an entire façade, but continued undaunted around a corner,

as on the original building of the Little theatre.

Mid-19th Century Onward. —Distinctive national characteristics in the design of ironwork gradually tended to disappear in Europe, due to increased travel and communications between countries. The influence of French Renaissance architecture (modified or revived) continued to exert a viable effect where the acceptance of the *art nouveau* (last quarter of the 19th century) was flaccid or denied. However, in England 18th-century designs continued with slight modifications. In the U.S. probably the most important force, prior to World War I, was exercised by architects trained in Paris, with the result that ironwork designs were similar to French work of this period.

The increased mechanization of all forms of manufacture understandably affected the character and use of ironwork. As the cost of cast iron came down, its use increased. Because wrought iron is produced by hand by beating red-hot iron on an anvil, not much change was possible through increased mechanization, whereas the casting of molten iron lent itself to improved equipment and techniques. The lowered cost of duplicating ornamental cast-iron components and the introduction of structural steel parts expanded the usage of ironwork to the modest building, whereas it had been generally confined to public or monumental structures. Foundries in the U.S. established a flourishing business in pierced cast-iron panels, modeled after Louisiana porch treillage.

Compared with prior periods, the last half of the 19th century will scarcely be commemorated as introducing enduring or beautiful ironwork forms. It was not until the first quarter of the 20th century that a master craftsman-designer gave impetus to a new conception of design forms and textures. Edgar Brandt of Paris broadened the scope of decorative usage by the rich inventiveness of his compositions, and by an entirely original approach which resulted in a wrought-iron texture that is akin to beaten silver. Examples of his work at the Exposition des Arts Decoratifs Moderne at Paris in 1925, had an immediate effect upon ironwork designed and executed in the U.S. during the great building boom which lasted until about 1930. During this period both wrought and cast iron enjoyed an unprecedented period of popularity, not only in the form of bank screens, entrance doors and grilles in public buildings, but as decorative grilles and gates in private homes. In many cases the craftsmanship equaled that of representative examples of the Gothic or Renaissance periods in Europe.

One of the most gifted and dedicated iron craftsmen in the U.S., Samuel Yellin of Philadelphia, raised the standards of wrought-iron craftsmanship to its apex during the 1920s. He not only trained an atelier of craftsmen for the first time in the U.S., but by his efforts, wrought iron was recognized as being capable of enriching even the most monumental building. Yellin's influence was ended by the depression of the early 1930s. As building activity declined after 1930, so did the use of ironwork, but it did not increase with the revival of building after World War II.

TECHNIQUE

Wrought Iron

Wrought iron is the type of ironwork that is forged on an anvil. There are no fabrication similarities to cast iron, which is poured in a molten state into prepared sand molds. There are three kinds of iron, whose physical characteristics vary chiefly according to their carbon content: wrought iron has .04%; machine, open-hearth or Bessemer steel has .2% to .6%; cast iron has 2% to 6%.

FIG. 4.—WROUGHT-IRON SMITH'S TOOLS

(1) Sledge; (2, 3) Top swages; (4, 5) Twisting bars; (6) Flatter; (7) Set hammer; (8) Scroll starter; (9) Cross-peen hammer; (10) English anvil; (11) Top fuller; (12, 13) Hot chisels; (14, 15) Bottom scroll forks; (16) Bottom swage; (17) Bottom fuller; (18) Mandrel; (19) Bottom swage; (20) Top fuller; (21) Scroll fork; (22) Bottom swage; (23) Heading tool; (24) Special twisting bar; (25) Dividers; (26) Twisting bar; (27) Link tongs; (28) Hollow bit or bolt tongs; (29) Scroll form; (30) Bottom swage; (31) Scroll form; (32) Special tool; (33, 34) Twisting bars or scroll forks; (35) Bending tool used in vise; (36) Punch

Properties.—Wrought iron is fibrous in structure and light gray in colour. It can be hammered, twisted or stretched when hot or cold. The more it is hammered, the more brittle and hard it becomes, but it can be brought back to its original state by annealing (heating and then cooling slowly). It will not shatter when dropped.

The grade of wrought iron least susceptible to rust, yet the most malleable and tough, is called Norway or Swedish iron. Among the chief sources of the ore are the bottoms of shallow Swedish lakes, where from 4 to 6 in. are deposited over a period of 15 to 30 years. The usual forms of wrought iron available to the craftsman are rods or bars, and thin plates. It is from these that his final product must be fashioned on an anvil.

Fabrication.—From earliest times, the smith has had a forge to heat the iron, an adjacent water tank in which to cool it, an anvil on which to form it, plus a wide assortment of hammers and tools. One of the few changes has been the mechanization of the blower at the forge, in place of the hand- or foot-operated bellows. The smith knows from the colour of the heated iron when it is at the optimum temperature for a specific operation; dark red indicates suitability for surface finishing; bright or light red show that the iron is malleable but the surface will scale and it is therefore not suitable for finishing; light yellow denotes a good forging temperature; and white designates the correct temperature for welding.

The most important tool is the anvil. The English type, generally used for forging wrought iron, has a flat top surface, which is used as a solid base for hammering the heated iron into shape, for welding, for splitting or for incising decorative chisel marks in the hot iron. One end of the anvil is shaped like a pointed cone, and is used for forming curved surfaces. The other blunt end, or heel, has one or two square or rectangular holes on top, into which fit various tools which are used for holding one end of a bar, making twists or holding scroll forms.

Design.—The two most important factors in wrought-iron

design are: (1) the form of the material (bars, rods and thin sheets); and (2) the relatively short time period in which iron can be forged while hot. Although the Spanish craftsmen of the late 15th century proved they could work almost impossible shapes in their unsurpassed cathedral grilles, this type of ironwork is not considered a realistic exploitation of the material. Ideally wrought-iron design should use forged bars and rods in imaginative forms, practical, yet decorative. Ornamentation is most successful when it is an integral part of the design (twisted bars, scrolls, chisel mark incisions, etc.), rather than a realistic imitation of nature, riveted on afterward. From the anvil is derived the expression, "to strike while the iron is hot," and this implies spontaneity and rapid hammer blows. The wrought-iron craftsman should not be expected to repeat with meticulous exactitude one intricate component after another. In fact, wrought iron by a master craftsman is esteemed for the variations which naturally occur.

FIG. 5.—CHISEL MARK ORNAMENTATION

The individual components of a wrought-iron design are often plain or twisted rods, with or without chisel mark incisions. They are frequently composed as a series of straight, parallel members, or in combination with scrolls, or a repeat design of some geometric shape such as the quatrefoil. Where two curved members are tangent, they are characteristically secured together by bands or collars, rather than by welding. Where two straight bars intersect, it is accredited craftsmanship to make the vertical bar pierce or thread the horizontal member. Grilles consisting of two series of parallel small-diameter rods, one series at right angles to the other, were sometimes interlaced or woven in decadent periods.

The term *repoussé* refers to three-dimensional, ornamental wrought ironwork. Depending upon the depth of the relief, various fabrication techniques may be employed. Sheets $\frac{1}{16}$ in. or less in thickness generally are used. The general configuration of the modeling is obtained by beating the back of the sheet; the final details are embossed on the front face. The finer the scale and detail, the more work which must be done when the iron is cold. A *repoussé* design may be pierced, but this term usually connotes a solid sheet forged into a mask, a shield or an entire embossed panel. The traditional means of setting off a cutout *repoussé* design was to superimpose it on a vermilion-coloured background panel. Modern approximations of *repoussé* work consist of mechanically stamped designs touched up with random hammer blows.

Care.—The texture of wrought iron is one of its principal assets, so painting it in order to prevent rust is not nearly as desirable as preserving the highlights of the original finish with wax. Professional craftsmen recommend removing all traces of rust by rubbing with emery cloth, augmented by a few drops of turpentine if the rust is heavy. Then the entire surface should be rubbed with any good liquid floor wax, or beeswax dissolved or softened in turpentine. After about 15 minutes when the wax has set, the surface should be rubbed with a soft cloth. This treatment should be repeated about once every three months.

FIG. 6.—EXAMPLES OF THE DECORATIVE POSSIBILITIES INHERENT IN TWISTED BARS

Cast Iron

Properties.—The carbon content of cast iron varies from 2% to 6%. Cast iron is melted in a furnace or cupola, stoked with alternate layers of coking iron, then poured into prepared sand molds. After the cast iron cools in the mold, the sand is cleaned off, and the work is virtually complete. Its shape is fixed, and while a casting can be slightly trued up by the judicious use of a hammer, it is in no sense as workable as wrought iron. Because it is brittle, it is almost certain to shatter if dropped.

Fabrication.—An iron casting is not the creation of a single craftsman, but the combined result of the skilled efforts of several groups of artisans. There must be an architect's or designer's drawings at full size, showing in detail all the features of the design. From these drawings full-size models or patterns must be made in wood, plaster or wax, depending upon the nature and the intricacy of the casting to be made. These patterns must be made slightly over-sized, according to a shrinkage scale; when the molten iron cools it will be slightly smaller than the patterns used in the molds.

The next step is to use the patterns to make sand molds, into which molten cast iron will be poured. For each casting there must be one sand mold for the back face of the casting (the cope), and another for the front or finished face (the drag). These two molds must be made so that when fitted and clamped together, there will be a space between. When this space is filled with molten metal and cooled, the result will be a casting with the desired size, shape, thickness and surface ornamentation of the pattern. If the casting is to be an ornamented panel, with a raised centre portion, a wood pattern might be used, with the ornamentation either carved in wood or applied. The drag mold (for the front face of the casting) is prepared by first placing on the foundry floor a plain-surfaced follow board. The pattern is placed on this, face up, supported by a bed board, in cases where the pattern has a raised centre portion. A parting powder is dusted on the face of the pattern (so that at a later stage the sand will not cling to the pattern when it is removed). Then the pattern is sprinkled or riddled with facing sand, which is firmly rammed as it is added. Finally heap sand is added until the rectangular, boxlike drag is filled to the top edge. A bottom board is then clamped on the top to hold the pattern and sand in place. Then the entire drag is turned upside down. The bed board, which had been on the floor and now is on the top, is removed. The pattern is then very carefully withdrawn from the sand, and its imprint inspected to be certain that it is a precise duplicate (reversed of course) of the pattern. Slight imperfections in the sand surface are filled if necessary, and loose sand is removed.

The next step is to repeat the same process for the cope, the sand mold for the back face of the casting. When completed, there thus will be two rectangular boxes, each rammed with sand, bearing the imprint of the pattern, and a space between them equal to the thickness of the metal. The drag remains on the foundry floor, but the cope is superimposed, being lifted in place with a crane if it is large. The sand of the (upper) cope mold has funnel-shaped openings provided (sprues), into which the molten metal will be poured. Horizontal grooves are then made in the sand of the cope called gates, which will provide tunnels for the metal to flow from the vertical sprues. In addition, there are risers (grooves in the sand located as far as possible from the sprues) to allow gases and displaced air to escape. The molten cast iron is ladled until the metal begins to fill the risers. When pouring a very large casting, a reservoir or pouring basin is provided above the cope, to contain sufficient molten metal to supply the entire mold simultaneously.

Technical metallurgical knowledge is required both in preparing the cast iron in the furnace or cupola, and in determining when the iron is right for pouring. Mechanical skill is necessary in ladling the molten metal from the cupola into the mobile mixing ladle, and from the latter to the prepared sprues of the cope. Foundries usually operate on a schedule so that the pouring of all molds is done toward the end of the working day. About two

or three minutes after a mold is poured, the iron is said to be set. At this stage there are two foundry practices. In one, the clamps which hold the cope and drag together, are loosened, the cope is removed, and the molder in charge estimates where the casting should be entirely uncovered or "stripped" of sand, or, whether to uncover only those parts of the casting which have the thickest metal, and to retard those areas where it is thinnest by shoveling on more sand in order to equalize the shrinkage rate between thick and thin parts. Skilled manipulation at this point determines the difference between a casting that is true and satisfactory, and one that is warped, and will consequently require tedious labour to straighten out. On the other hand, some foundries allow the casting to cool as slowly as possible, without removing any sand, and perform any straightening later. A casting which has cooled slowly is more readily straightened than one which has done so quickly.

FIG. 7.—CAST-IRON FABRICATION: (TOP) DRAG BEING PREPARED; (CENTRE) DRAG IN POSITION WITH COPE SUPERIMPOSED; (BOTTOM) COPE FROM ABOVE, SHOWING GATES AND RISERS
(A) Follow board; (B) bed board; (C) pattern; (D) drag outer frame; (E) bottom board; (F) cope outer frame; (G) sprues; (H) gates; (J) gaggers to reinforce sand; (K) risers

After the castings have cooled overnight, they are sandblasted to remove any sand that may adhere. Unwanted protuberances, such as those where gates and risers were located, are ground or cut off. Following this, the process is not unlike the operations in a woodworking shop; edges and surfaces that must conform to narrow tolerances are rimmed and planed. Ornamental features in cast iron cannot be chased and polished as in cast bronze. If the ornamental cast-iron details are not replicas of the original pattern, the only recourse is to make a new casting. *See* also CAST IRON.

Design.—From the foregoing description of fabrication, it is obvious that certain forms are more suitable to cast iron than to wrought iron. For example, if repetitive balusters or columns, or panels with low-relief ornamentation are desired, cast iron is the most suitable material. In the U.S. excellent examples are to be found in the cast-iron railings and porches of Charleston, S.C., and New Orleans. Some of the patterns used in the 19th century are still being used today. The same is also true of ornamental firebacks (for the rear of fireplaces). Some good examples of 20th-century cast ironwork are the imposing entrance and window spandrels of the Fidelity Mutual Life Insurance building, Philadelphia (Zantzinger, Borie & Medary, architects); the window frames and panels of the Integrity Trust Company building, Philadelphia (Paul Cret, architect); the entrance and show window of the Packard Motor building, Philadelphia (Albert Kahn, Inc., architect, and Philip S. Tyre, resident architect); the mullions and window spandrels of the Home Savings bank, Albany, N.Y. (Dennison & Hirons, architects); and the entrance to the Federal Trust building, Newark, N.J. (Dennison & Hirons, architects, George E. Jones, associate architect).

Care.—The material has a fairly uniform, cold, gray colour when the casting is cooled and cleaned. The usual finish procedure is to give the casting an initial coat of red lead, red oxide of iron paint, or a gray priming coat, followed by whatever final coat is desired. If there is delicate modeling which will be lost under successive coats of paint, it is recommended practice to burn off the old paint, and start off again with a priming coat, followed with a finish coat. IRONY, a form of speech in which the real meaning is concealed or contradicted by the words used. Often confused with sarcasm, which arises from contempt and is uttered in a snarling tone, irony arises from awareness of contrast, a sense of weakness or of inevitability, and is uttered with a "dry mock," controlled pathos or great pity for oneself or others. Socratic irony consists of feigned ignorance as a method of dialectic. *See* FIGURES OF SPEECH: *Figures of Degree of Emphasis.* (G. W. A.)

IROQUOIS, a confederacy or league of North American Indians which originally included the Mohawk, Oneida, Onondaga, Cayuga and Seneca nations. During the 17th and 18th centuries the Iroquois, or Five (later, Six) Nations of New York, were the native people of greatest political importance north of Mexico. Iroquois is a French name derived from uncertain Algonkin or Huron sources, and also has been adopted for the linguistic family of which the Five Nations were the most durable representatives (*see* INDIAN, NORTH AMERICAN).

The Iroquoian Family.—The Iroquoian linguistic family occupied a continuous territory around the lower Great Lakes, sur-

rounded by Algonkian-speaking peoples, with southeastern outliers at tidewater and in the Appalachian highlands. In the Susquehanna and St. Lawrence valleys and bordering Lakes Ontario, Huron and Erie lived Iroquoians including the Huron, Tobacco (Tionontati) and Neutral (Neuter) to the north; the Erie, Wenro (Wenrohronon) and Iroquois proper to the south; and the Andaste or Conestoga (Susquehanna) in Pennsylvania. The Laurentian Iroquois who received Jacques Cartier in the period 1534–41 spoke a distinct language representing an ancient cleavage within the Iroquoian speech community, which is not accounted for by disappearance into Mohawk-Onondaga or Huron-Wyandot. The linguistic place of the tidewater languages, Nottaway and Meherrin, from Virginia south of the James river, is unknown; but the Tuscarora of the Neuse river, N.C., has affinities with Mohawk and Huron. Cherokee, from the Great Smoky mountains, is the most divergent branch and the southern outpost of Iroquoian speech.

The Iroquois-speaking tribes were semisedentary, practised maize agriculture, palisaded their villages in time of need, and more than 100 long houses of multiple-fireside families sheltered maternal lineages that painted their crests on the gable ends. Living south of the range of the paper birch, they stripped elm bark for sheathing houses, for containers ranging from dishes to barrels and for canoe building. Birchbark canoes were available to the Huron of Georgian bay by trade from Algonkin neighbours. A village band of several hundred persons was the social and economic unit. Gangs of men built houses, erected palisades, fished, hunted, traveled, traded, gamed, defended the village against attacks and went on the warpath. Outside the towns, parties of women, each directed by a matron, worked fields of maize, beans and squash, averaging 3 to 6 ac. per family. After harvest, family hunting parties ranged far into the forests, camping until the festive midwinter homecoming, when they returned with dried venison and consumed grain stored in pits and bark barrels. For several weeks between maple sugaring and planting, settlements were evacuated to attend the March migration of now extinct passenger pigeons, and prodigious quantities of birds were taken. Spring runs of fish drew families to nearby streams and lake inlets to erect weirs and traps for spearing. Old women gathered spring greens to tide them over the hungry period before the first berries ripened.

The Long House family was the image for Iroquois society; households, or blood lineages, were projected into clans, clans into moieties, moieties into tribes or nations, and nations into leagues or confederacies. Common to all the league tribes were the exogamous Bear, Wolf and Turtle clans. The Seneca had an eight-clan system of two moieties (Bear, Wolf, Beaver, Turtle; and Deer, Snipe, Heron, Hawk) which had Cayuga and Onondaga counterparts. The moieties or sides had overtones of kinship, but functioned mainly in games, at ceremonies and at funerals.

Kinship and locality were the bases for political life. Each community had its council of adult males who guided the village chief, or chiefs. Peace chiefs concerned with civil affairs were appointed by women to represent their clans, and the office descended to the sister's son. Speakers of the council (the mouth of the chiefs) were often chiefs of merit called pine tree chiefs whose rank, as well as that of war chief, was an achieved status and not hereditary. In forest protocol speakers named the hierarchy of civil chiefs, warriors, women and the public, which were the circles of society ranged around the council fire. The Iroquois were addicted to meetings, spending considerable time in council. Groupings for council were determined by locality, sex, age and the specific question at hand, and each had its own protocol and devices for gaining consensus.

Elaborate Iroquois cosmology was based on the myth of a woman who fell from the sky, and featured deluge and earth-diver motifs. No other tribes showed such a preoccupation with supernatural aggression and cruelty, sorcery, torture and cannibalism. This literature was relieved by occasional beautiful star myths and journeys to the other world. Formal religion consisted of six agricultural festivals featuring long prayers of thanks to a hierarchy of spirit forces between mother earth and a superimposed sky world. Much ritual sought to propitiate earth-bound malefic spirits that were most active in dreams between the frosts. The "Handsome Lake" religion (named after a visionary Seneca) perpetuated many of these aspects and combined them with Christian ethics. Rituals imparted sanction to political activity, giving rise to the Indian treaty literature of the 18th century, and supporting hopes of sovereignty among nativists who hoped to restore the league after it became ineffective.

Warfare was so ingrained in Iroquois personality, and self-respect so dependent on achieving personal glory, that individualism outweighed the philosophy of peace. The elders continually complained that they could not control the warriors, their young men. Warfare kept down the population, sustained by women farmers who freed warriors from hunting. Economic warring in the fur trade has been overemphasized by historians. Captives were tortured, enslaved or adopted to replace dead kinsmen, and made up much of the Iroquois population in the late 17th century. Adopted captives embraced Iroquois values, some becoming leaders, and some white captives preferring Indian society to resuming their earlier lives.

A major problem in Iroquois history has been to explain their linguistic-cultural position. Cherokee culture shows resemblances to the northern Iroquois which are at first impressive, but on closer study fit a culture adapted to a Muskogean (Creek) Appalachian habitat. The northern Iroquoian tribes more nearly resemble Muskogean societies than the Algonkin hunters north of the St. Lawrence. Mohawk and Oneida cultures have many traits of the neighbouring Mahican and Delaware. The once popular theory which held that Iroquoians migrated up the Ohio valley as intruders in an Algonkian culture area lacks empirical support. Approximately 1,300 years by radiocarbon dating separate the most recent Hopewell mound builders from the earliest (*c.* A.D. 1400) Iroquois in the northeast. Moreover, maize agriculture preceded the Iroquoians into the lower Great Lakes area among Point Peninsula and Owasco peoples between the Hopewell and Iroquois dates. Iroquois pottery types from Point Peninsula, as well as discoveries in Ontario, support the theory that Iroquois developed out of resident cultures. In eastern New York state the latest Owasco site was found to be separated by a scant 100 years from the earliest Mohawk, suggesting they were competing cultures.

Linguistically, the widest cleavage in the Iroquoian family is between the lone southern branch, Cherokee, and all the rest, representing a time depth estimated at not less than 3,500 years. Tuscarora represents a split from the northern languages of about 2,000 years, and the languages of the Five Nations diverged at least 1,200 years ago, when classic Iroquois culture is first recognizable from archaeology.

The Iroquois League.—The Five Nations of the Iroquois league characterized themselves as "the people of the extended house." The Mohawk, Oneida, Onondaga, Cayuga and Seneca (*qq.v.*) lived in this order from Schoharie creek westward across central New York state to the Genesee river; from door to door the "Longhouse" extended nearly 180 mi. between what are now Amsterdam and Rochester. Tradition credits formation of the league to Dekanawidah, born a Huron. He is said to have persuaded Hiawatha, an Onondaga living among Mohawks, to abandon cannibalism and advance "peace, civil authority, righteousness and the great law" as sanctions for confederation. The Dekanawidah epic, a masterpiece of aboriginal literature, recited from memory on state occasions, became available in several versions to ethnologists in the early decades of the 20th century. Iroquois sources (18th century) place the league's beginning between 1570 and 1600, consistent with archaeological and linguistic evidence and the disappearance of the Laurentians between Cartier's and Samuel de Champlain's voyages. What Benjamin Franklin termed "a league of ragged villages" had arisen voluntarily, preserving the integrity of each tribe. They united in common council, installing the 50 existing clan and village chiefs as founders in a common ceremony of condolence. The Mohawk and Oneida had 9 representatives each, the Onondaga 14, Cayuga 10 and Seneca 8. Size of delegation did not affect decisions since each tribe had one vote; unanimity was the rule. The Mohawk and Seneca delegations would confer separately and together before handing the issue

across the fire to their "offspring" or "younger brothers," the Oneida and Cayuga. These, in turn, would repeat the process before sending the question on to the Onondaga fire keepers, whose speaker as host opened the council, presided and voiced the mind of the Five Nations.

League chiefs were peace chiefs, their joint jurisdiction embracing civil affairs at the intertribal level. Each chief was answerable to his own tribal or clan council and ultimately to the matron who presided at his nomination by the women of the lineage in which the title passed. Their nomination required ratification by clan, tribal and league councils. For propositions to the league council there was a regular chain of clearances from family to clan, to moiety, to town, to nation or tribal councils, and down again. The relationship of league chiefs to war chiefs is not clear in historical sources. Best known to history were the pine tree chiefs, awarded their rank for wisdom and oratory, and including men of real ability (like Red Jacket) who made policy by voicing the opinions of the league, of warriors and of women. A fourth class of chiefs by virtue of age and wisdom constituted the town council and heard deputies from the warriors, the women and the league. J. F. Lafitau, a Jesuit, described (1724) this council as ". . . a greasy assemblage, sitting *sur leur derrière,* crouched like apes, their knees as high as their ears, or lying, some on their bellies, some on their backs, each with a pipe in his mouth, discussing affairs of state with as much coolness and gravity as the Spanish Junta or the Grand Council of Venice."

The Iroquois league differed from native confederacies in the northeastern woodlands only in being better organized, more consciously defined, and more effective. The Huron also used the ritual of condolence to install chiefs to take the place of deceased founders, but the Iroquois used the rite constantly to stress the importance of the "great peace." They persuaded colonial governments to use the ritual in negotiations and fostered a tradition of political sagacity based on ceremonial sanction rather than the occasional superior individual. Even though war parties got out of hand and dissipated the fruits of diplomacy, public policy was made at Onondaga and success strengthened it. The league lacked administrative control, and the nations did not always act together, but spectacular successes on the warpath compensated for this and were possible because of security at home.

For the century and a quarter before the American Revolution the Iroquois stood athwart the path from Albany, N.Y., to the Great Lakes, keeping the water-level route from permanent settlement by the French and containing the Dutch and English. Their success has been variously ascribed to their strategic position astride the first gap in the Appalachian chain and atop the sources of five river systems, accidents of history, their genius as politicians, the terror of their small war parties, their possession of firearms, and their role in the fur trade.

During the formative period of the league, the Laurentian Iroquois abandoned the sites of Hochelaga (Montreal) and Stadacona (Quebec) to Algonkins, the Huron concentrated toward Georgian bay, and the Five Nations had withdrawn to central New York. The Laurentians remain a mystery. They had their own language, yet their pottery is Onondagalike. Tradition says the Mohawk moved from the Laurentian region, but most historians favour the Huron claim.

For a generation the tribes of the new league, beset from all sides, enjoyed no advantage save removal from contact, and barely held their own with the Mahican and related tribes who traded freely with the Dutch. By 1628, no longer cowed by firearms, the Mohawks had emerged from "castles" secluded in wooded highlands to defeat the Mahican and lay the Hudson valley and New England tribes under tribute of goods and wampum. For another decade the beaver trade exceeded 10,000 skins per year, when the Mohawks themselves obtained firearms from competing independent traders mainly at Ft. Orange. Acquiring new weapons coincided with the local depletion of beaver but enabled league members to carry the beaver wars against far-flung enemies. In a decade they turned west and dispersed the Huron (1648–50), Tobacco (1649), Neutral (1650–51) and the Erie (1654–56). Two Seneca towns were composed largely of captives from these nations, besides individuals distributed through the league to produce more Iroquois in the next generation. To the upper lakes and into the Ohio woods fled scattered remnants of the defeated peoples. Hurons to become Wyandots, and Eries to become Mingos; later merging in Cayuga and Seneca outliers. Large palisaded towns had proved vulnerable to large-scale assault, whereas family hunting bands living scattered in the forest in the Algonkin manner could resist indefinitely. The Andaste, though often better armed and attacking league towns in 1662, finally succumbed in 1675, having first been assaulted by the militia of Maryland and Virginia. Andaste who were not adopted by the Seneca fled to Virginia and were exterminated during Bacon's rebellion. Next, various eastern Siouan allies of the Andaste against the league felt the Iroquois ax, and by the mid-18th century all piedmont tribes were incorporated or destroyed. To the west the Miami and Illinois were badly mauled "for cutting down the Tree of Peace and hunting beaver on Iroquois lands." Only the distant Ojibwa set a boundary to Iroquois conquests in the west.

If the central fact of 17th-century intertribal rivalry was the fur trade, so in the 18th century these activities depended on the French and British struggle to control the continent. Despite the power of Iroquois war parties which ranged to the Catawba of South Carolina and the Cherokee, and even into the canebrakes of Georgia against the Creek, they did not settle or effectively control the vast area they claimed. Rather, Iroquois delusions of empire were converted to Britain's advantage by Sir William Johnson (*q.v.*), who controlled the destiny of the Iroquois for over 20 years until his death in 1774.

By 1712 the Delaware were under tribute to the league. The Tuscarora, having left Carolina the previous year, returned north in stages, and became the sixth nation of the Iroquois confederacy. Following official recognition in Albany (1722) the Iroquois were known to the English as the Six Nations.

The Iroquois were consistent and bitter enemies of the French, who had espoused their traditional foes. Yet, though they were in friendly trade with the Dutch, and afterward the English, their first treaty (1624) was with the French. Whether or not they loved the Dutch and their English successors, the Iroquois depended on Albany for European goods which were cheaper than in Montreal, and Albany was never attacked. Though twice invaded by the French, the Iroquois never succumbed, retaliating devastatingly in Canada. But for the Iroquois, the English colonials, who could not field an army in time, would have been flanked behind by the French, and the history of the continent might read differently. The Iroquois quest for neutrality was far from a complicated game of balancing the two European powers, for the league lacked decision and the power for consistent action. Nonetheless, theirs was a remarkable achievement for an aboriginal people that could field only 2,200 men from a total population of scarcely 12,000.

During the American Revolution, a schism developed among the Iroquois. The Oneida and Tuscarora espoused the revolutionary cause, and the rest (led by chief Joseph Brant's Mohawk loyalists) fought the war out of Niagara, decimating their ancestral valley. John Sullivan's expedition of 1779 destroyed the fields, granaries and morale of the Six Nations. The Mohawk and Cayuga mainly withdrew to the Grand river in Canada, but the Onondaga and Seneca remained in their ancient seats. The Oneida departed for Wisconsin a generation later. Having acknowledged defeat in the second Ft. Stanwix treaty (1784), the Six Nations and the U.S. made a treaty at Canandaigua, N.Y., in 1794, in which each pledged not to disturb the other in lands they had relinquished or reserved.

In the 1960s about 8,000 persons inhabit six Iroquois reservations in New York, and eight reserves in Canada contain about 16,000 persons of Iroquois descent. Although considerable intermarriage with whites has occurred, Indian features are still evident. Iroquois life is remarkable in retaining parts of the old culture while engaged in modern occupations.

IRRATIONAL NUMBERS are real numbers that cannot be expressed as integers or quotients of integers. For example, there is no number among integers and fractions that solves the problem of finding the square root of 2, or a number whose square is 2. A counterpart problem in measurement would be to find the diagonal of a square whose side is one unit long. It thus became necessary in the history of mathematics to extend the concept of number to include irrational numbers. Without such an extension, many problems involving such operations as subtraction, division and the extraction of square root cannot be solved. The square root of every positive integer that is not a perfect square, for example, is an irrational number.

The imposition of secrecy on the ancient Pythagoreans (who saw religious meaning in numbers) may have been related to a desire to conceal the insufficiency of rational numbers in solving such problems. A way out of the difficulty (4th century B.C.), attributed to Eudoxus and adopted by Euclid, amounts not so much to the introduction of irrational numbers as to a scheme by which such numbers can be avoided. A period of over 2,000 years followed in which mathematicians seem to have been unconcerned about such niceties. The problem again arose in the more critical and rigorous mathematics of the 19th century.

One of the simplest approaches to the problem is to find approximate solutions; for example, to consider a nonrepeating infinite decimal derived from a fraction whose square is very nearly 2, and to continue calculation until a certain number of digits gives a satisfactory approximation. A similar situation arises in finding the number π (the ratio of the circumference of a circle to its diameter). Many mathematicians consider this infinite decimal fraction as being, or representing, the irrational number. In applied problems, for example, π has been usefully approximated by using the fraction $22/7$. Of course, it is not possible to calculate the whole infinite decimal, but a rule may be given that specifies the computation of any desired number of successive digits.

The problem may also be approached by noting that any fraction is either too small or too large for the irrational number in question. This separates all fractions into two classes such that every fraction in one class is less than every fraction in the other. Such separations are called Dedekind cuts, and it is possible to treat these cuts as numbers by defining arithmetical operations on them. This procedure is equivalent to the introduction of irrational numbers by approximations. Other methods have been offered for dealing with irrational numbers, but none of them avoids all the difficulties presented.

These difficulties, however, do not prevent mathematicians, scientists and engineers from making use of irrational numbers. Efforts to avoid their use would tremendously complicate the expression of many useful ideas. For further discussion of irrational numbers, *see* NUMBER.

IRRAWADDY, the principal river in the Union of Burma, traversing the centre of the country and running throughout its entire course within Burmese territory. It is formed by the confluence of the Mali Hka and N'mai Hka (*hka* being the Kachin word for "river") in 25° 45′ N. The N'mai is the eastern branch. The definite position of its source is still uncertain, and it seems to be made up of a number of considerable streams, all rising within a short distance of each other in about 28° 30′ N. It is shown on old maps as the Lu river of Tibet; but it is now quite certain that the Tibetan Lu river is the Salween, and that the N'mai has its source or sources near the southern boundary of Tibet, to the northeast or east of the source of the Mali. At the confluence the N'mai is larger than the Mali. The general width of its channel just above the confluence is 350 or 400 yd. In the rainy season this channel is filled up, but in the cold weather the average breadth of the river is from 150 to 200 yd. The N'mai is practically unnavigable. The Mali is the western branch. Like the main river, it is called Nam Kiu by the Shans. It rises in the hills to the north of the Putao (Hkamtī) country, in about 27° 50′ N. Between Putao and the confluence it runs in a narrow channel through continuous hills. About 1 mi. above the confluence it is 150 yd. wide in January and 17 ft. deep, with a current of $3\frac{1}{4}$ mi. an hour.

Steam launches can ascend from Myitkyina to the confluence only at the height of the rainy season. Country boats ascend to Laikaw or Sawan, 26° 2′ N., all the year round, but can get no farther at any season. From the confluence the river flows in a southerly direction as far as the confluence of the Kaukkwe stream, a little above Katha, where it again turns in a southerly direction, as far as the great bend near Mandalay, where it is joined by the Myitnge. Thence it follows a westerly course and is joined by the Mu river—an important source of water for irrigation in the Shwebo district—on the north bank. Beyond Myinmu it again assumes a southerly direction and is joined by its chief tributary, the Chindwin, described below. Between the confluence and Mandalay the river varies in width from 50 to 4,000 yd. It is narrowest in the three well-known "defiles." The third or upper defile lies between Myitkyina and Bhamo and is entered 3 mi. below Sinbo by a channel only about 50 yd. wide and below this, throughout the defile, it averages about 100 yd. in width.

At the "Gates of the Irrawaddy" at Poshaw two prism-shaped rocks narrow the river to 50 yd., and the water banks up in the middle with a whirlpool on each side of the raised pathway. All navigation ceases there in the floods. The defile ends at Hpatin, and below this the river widens out to a wet-season channel of 2 mi., and a breadth in the dry season of about 1 mi. At Sinkan, below Bhamo, the second defile begins. It is not so narrow, nor is the current so strong, as in the third defile. The narrowest place is more than 100 yd. wide. The hills are higher, but the defile is much shorter. At Shwegu the river leaves the hills and becomes a broad stream, flowing through a wide plain. The first defile is tame compared with the others. The river merely flows between low hills or high wooded banks. The banks are covered at this point with dense vegetation and slope down to the water's edge. Here and there are places which are almost perpendicular, but are covered with forest growth. The course of the Irrawaddy after receiving the waters of the Myitnge opposite Sagaing, as far as 17° N. lat., is exceedingly tortuous. Below the junction of the Chindwin and Irrawaddy, the tributary streams throughout the dry belt are but small, though some, especially those in the Minbu district, are important sources of water for irrigation, and others, like the Yaw Chaung, are used for floating teak logs to the main river. At Akauktaung, where a spur of the Arakan hills ends in a cliff 300 ft. high, the river enters the delta, the hills giving place to low alluvial plains, now protected on the west by embankments. From 17° N. lat. the Irrawaddy divides and subdivides, converting the lower portion of its valley into a network of intercommunicating tidal creeks. It reaches the Andaman sea in about 16° N. lat. by nine principal mouths. Practically no water, however, now reaches the sea through the western and eastern mouths (the Bassein and Rangoon rivers respectively), though these are the ones used by seagoing ships to reach the ports of Bassein and Rangoon.

The largest tributary of the Irrawaddy is the Chindwin (*q.v.*), its entire course being in Burmese territory. The geomorphological history of the Irrawaddy basin is an interesting one. It would seem that there were originally two parallel streams, the Upper Irrawaddy-Sittang and the Chindwin-Lower Irrawaddy. Slight earth movements perhaps connected with an eruption of Popa Mt. (4,981 ft.) deflected the Upper Irrawaddy westward and beheaded the Sittang, now a small misfit stream. Especially where it passes through the dry belt the Irrawaddy is bordered by extensive gravel-capped terraces which have yielded human artifacts of distinctive cultures, by the early 1960s still imperfectly studied. One particularly well-marked terrace on which most of the town of Yenangyaung is built is approximately 100 ft. above river level and gives rise to some imposing river cliffs.

The area of the catchment basin of the Irrawaddy is 158,500 sq.mi.; the total length of the main river from its known source

to the sea is about 1,300 mi. Throughout its course, except through the defiles, it is full of islands and sandbanks; its waters are extremely muddy, the mud being deposited partly in the delta, in part being carried far out to sea. The river begins to rise in March; about June it rises rapidly, and attains its maximum height about September. The total flood discharge is between 400,000,000 and 500,000,000 metric tons of 37 cu.ft.

From Mandalay up to Bhamo the river is navigable for large steamers all the year round for a distance from the sea of nearly 1,000 mi.; but small launches and steamers with weak engines are often unable to get up the second defile in the months of July, August and September, because of the strong current. The steamers of the Inland Water Transport commission which has replaced the old Irrawaddy Flotilla company (whose 600 ships were scuttled at the time of the Japanese invasion in 1941–42) go up and down several times a week, but the mails are carried to Bhamo by a ferryboat from the railway terminus at Katha.

The Irrawaddy river itself supplies no main irrigation works, although agriculture is concentrated on the alluvial lands of its delta; the great value of the river is as a highway and economic life line. It is the main means for goods to reach such important centres as the oil fields of Yenangyaung and Singu, which are not served by railway. The Irrawaddy is crossed by only one bridge, that below Mandalay, but there is a steam ferry at Henzada to connect the railway system on either bank. The vast delta (about 150 mi. wide and at its apex about 180 mi. from the sea) is one of the world's greatest rice producing areas.

The name Irrawaddy is also given to a division of Burma, coinciding roughly with the western three-quarters of the delta. It includes the districts of Bassein, Henzada, Maubin, Myaungmya and Pyapon.

See L. D. Stamp, "The Irrawaddy River," *Geog. Jour.*, vol. 95, pp. 329–356 (1940). (L. D. S.)

IRREDENTISTS, an Italian patriotic and political party which was prominent in the last quarter of the 19th century. The name was formed from the words *Italia irredenta*—unredeemed Italy—and the party had for its object the emancipation of all Italian lands still subject to foreign (*i.e.*, Austrian, French and British) rule. The lands which they claimed as Italian were south Tirol (Trentino), Gorizia, Istria, Trieste, Ticino, Nice, Corsica and Malta. The agitation was, however, mainly superficial and sank into insignificance when the French occupation of Tunis in 1881 offended the Italians deeply, and their government entered into those relations with Austria and Germany which led to the triple alliance. The name "Irredentists" is also used of any other nationalist group aiming at the emancipation of any of their countrymen subject to foreign control.

IRRIGATION is the artificial application of water to land. Modern irrigation and the associated practices of drainage, fertilization, mechanization and mass production for special markets under professional management are producing a revolutionary efficiency in agriculture that, along with an attractive and profitable way of life, best guarantees food and fibre for the fast-growing population of the world.

Normally vegetation grows on soil watered by rain. Where rain is so seasonal that it does not meet the requirements of a particular crop or is deficient or practically nonexistent, the drying of the soil to an ever increasing degree retards, until it eventually prevents, vegetable growth. Irrigation can give better results than nature itself produces by fitful rainfall, because water can be given regularly just when it is needed.

This article briefly sketches the historical background of irrigation and the development of ancient and modern mechanical aids, and deals with methods of securing irrigation water, storage of water, legal title to water, principal systems of irrigation, little-used systems, drainage in relation to irrigation, irrigation practices, supplemental irrigation and a brief survey of irrigation throughout the world in the second half of the 20th century. For another method of farming with a limited natural supply of water *see* Dry Farming. *See* also separate articles on individual states and countries, as Egypt; Idaho; etc., and on rivers, as Colorado River; Nile; etc. *See* also Ground Water; Hydrology; Soil.

HISTORICAL BACKGROUND

The use of irrigation as an aid to the growth of vegetation is an ancient art. (*See* Agriculture, Primitive.) The probabilities seem to point to Egypt as its place of origin. The paintings and sculptures of ancient Egypt show that the peasantry bailed up water at least 4,000 years ago, and there is evidence of earlier irrigation there and in other parts of the ancient world which strengthens the belief that irrigation preceded, and made possible, the development of ancient civilization. Reliance was not placed entirely on direct labour; mechanical aids were invoked, and such machines as the *shaduf*, the *sakia* and Archimedes' screw were invented.

Ancient Mechanical Aids.—The simplest device for lifting water consists of a long tapering and nearly horizontal pole supported on a horizontal crossbeam about eight or ten feet above the ground. A skin or bucket is hung on a rope from the longer and thinner end and a counterbalance placed on the shorter and thicker end. The worker pulls down on the rope to fill the bucket, after which the counterbalanced end drops and raises the bucket of water to his hand, where it is emptied. Each of these devices can irrigate about two acres, and two or more of them can be placed one above another for the higher lifts. In Egypt this is called a *shaduf* or *shadoof*, while in India the name is *denkli* or *paecottah*.

The Egyptian *sakia* (called a *harat* or Persian wheel in India) is operated by oxen. It is so arranged that a vertical wheel turns continuously. Two parallel endless ropes pass over the wheel and are attached to buckets spaced a short distance apart. While half the buckets are descending and filling, the other half are rising full of water. At the top they tilt automatically into a prepared channel leading to the field. Each machine can irrigate from 5 to 12 ac., depending on the height of the lift.

The most ingenious of these old devices is the Archimedes' screw, which was invented about 200 B.C. in Syracuse. A corkscrew-shaped tube is placed in or around a wooden cylinder about one or two feet in diameter. One end of this 10- to 15-ft. cylinder is under water, and the other end rises about 3 ft. to the bank where water is discharged as the cylinder is rotated by hand. Knowledge of these mechanical aids probably spread to other ancient empires. All are still in constant use.

Modern Mechanical Aids.—Not until the era of steam, the internal-combustion engine and electricity, which brought with it the power to drive pumping plants of all kinds, was human and animal life relieved of almost all the duty of directly lifting water onto the soil. Irrigation makes use of such pumping plants in all sizes, ranging from one- or two-horsepower engines up to huge installations whose power is measured in thousands of horsepower and which are capable of dealing with great volumes of water.

Electric motors are now generally used for the larger pumping plants, diesel engines for those of moderate size and gasoline or liquid petroleum gas engines for smaller plants. Portable plants are available for areas up to several hundred acres. Usually the power and pump are directly connected in a single unit. Centrifugal pumps are preferred for lifting from open water, while turbine pumps are used in wells of a few feet to hundreds of feet in depth. The axial-flow or propeller pump that was developed in New Orleans, La., for drainage of that city, is best for lifting large volumes of water through low heads or differences in elevation. Each power plant and pump is designed by hydraulic engineers especially for the work which it is to accomplish.

An important mechanical development after World War II was the use of 20- to 40-ft. lengths of lightweight portable aluminum pipe with special couplings which permit the pipe to be quickly assembled, dismantled and moved to a new location on the surface of the ground. This is especially useful in portable irrigation systems, where the pipe is laid quickly over the ground, then dismantled and moved to another tract of land by one or two men, thus minimizing the investment necessary.

METHODS OF SECURING IRRIGATION WATER

Much irrigation water is pumped from ponds, reservoirs, lakes, streams, canals, pits and wells, occasionally as high as several hundred feet for valuable crops. The more abundant and cheaper

water supplies are found in the larger streams and usually are obtained therefrom by diversion dams without pumping. Often these structures raise the level of the water in the river and sometimes provide storage. From them, canals and many other types of structures convey and distribute the water over the land.

Canals.—Man was not satisfied with his efforts to supply water to the fields and early saw that he could assist nature by taking water from a river at a point higher upstream than the point immediately opposite his own particular field, and thus take advantage of the difference of level between these two points, or the fall of the river. Take the case of the fall of a river being only 12 in. in one mile—as is not unusual. As some slope must be given to the water in a canal to make it flow, and if this is, say, six inches in one mile, the canal water will stand higher by six inches at the end of each mile of length than the river opposite to it. Obviously, to establish fall sufficient to be effective under such conditions, a canal must draw its supply from the river many miles upstream of the areas it is intended to serve.

Diversion Dams.—That the use of diversion dams (also called weirs or barrages) as an aid to heightening water level is old there is no doubt, yet only in modern times has the idea been used to any great extent. These structures are built across a river so that a higher level can be produced on the upstream side of the dam simply by closing sufficiently the sluices, or gates, placed in them. This enables the water flowing at the higher level to irrigate the land much nearer the headworks of the canals taking off from either bank. Thus these structures, like the canal already mentioned, are devices for doing, almost forever without any further labour than adjusting the sluices, what hitherto had to be done, laboriously and expensively, by the aid of manual or mechanical work.

When these structures are necessary in those parts of a river's course where there is no other foundation than sand or silt, water is seldom raised more than ten feet. Whatever heading up of the waters is necessary, it should avoid reducing the silt-carrying power of the river.

STORAGE OF WATER

Reservoirs.—At an early stage man must have realized the advantage of storing water against periods of shortage, as rivers and wells run low at times even if they do not run dry. At what date reservoirs first came into use as an additional aid to a regular supply is unknown; the remains of ancient reservoirs throughout the world, however, testify to the antiquity of the idea.

The earliest form was probably the earthen embanked reservoir, or tank, as it is called in India. The tank suffers from the disadvantage of retaining all the silt contained in the water stored in it. In time this leads to practical obliteration and a new tank has to be constructed elsewhere. Reservoirs with masonry dams were also built. These, too, became filled with silt, and not until modern times, and until the Periyar dam was built in India (1895) with sufficient sluiceway near its base to pass all the flood-waters and arrest only the later clean supply, was the problem met and a reservoir constructed which, in a silty river area, could be depended upon to keep itself clear of detritus. A magnificent example is the dam at Aswan, on the Nile in Egypt (1902–34), where the whole of the heavy flood passes through the structure without dropping any of its silt content and only clear water is stored. Thus a nearly perpetual life is guaranteed to the reservoir.

When dams are built in rivers where relatively little silt is carried, it is anticipated that the reservoir will fill with silt only after a long time; then another storage dam will be built farther upstream. The original storage will be lost, but the difference in water level above and below the old dam will remain available for hydroelectric power.

In modern practice, storage reservoirs are often created by multipurpose dams that will make the water available for municipal supply, hydroelectric power, industry, irrigation and navigation while also giving protection against floods. Silt and polution control, fish and wildlife protection and recreation often are important by-products. A series of these dams on a stream and its tributaries often provides comprehensive, integrated, basin-wide development. In a few cases, water is stored in one drainage basin, or watershed, and conveyed for use into another. Seven of the world's eight greatest surface reservoirs are in the U.S. (*See* also DAM; RESERVOIRS.)

Natural Underground Storage.—Throughout the ages man has availed himself of a small part of the enormous supplies (exceeding those of all reservoirs and lakes, including the Great Lakes) of underground water, often called ground water (*q.v.*). Most of this water has accumulated over long geological ages, but some is replaced by current rainfall as used. Heavy pumping reduces the permanent supply and lowers the water table, or level of the water, in the ground, and both of these effects make pumping increasingly expensive, a condition already serious by the second half of the 20th century in the southwestern United States and elsewhere.

Perhaps the largest and cheapest supplies of ground water for irrigation are found in humid deltas and coastal plains where the water is not too salty. There the heavy rainfall maintains a relatively inexhaustible underground supply, and large river flows also are available. *See* also HYDROLOGY.

LEGAL TITLE TO WATER

Population increases were accompanied by an alarming growth in the variety of industrial and other water uses in the second half of the 20th century. It appeared that availability of adequate water would largely determine where civilizations would develop.

The right to use specific supplies of water for irrigation and other purposes has caused militant and legal action throughout history. While these contests for water rights (*q.v.*) continued between nations, states, cities, industry, agriculture and individuals, in the 20th century resort to force was rare. The respective claims were customarily settled through the considerable body of applicable law and by negotiation.

Priority of appropriation and use may be advantageous. However, the trend of settlements is toward giving less weight to priority and to the English common-law principle of riparian rights,

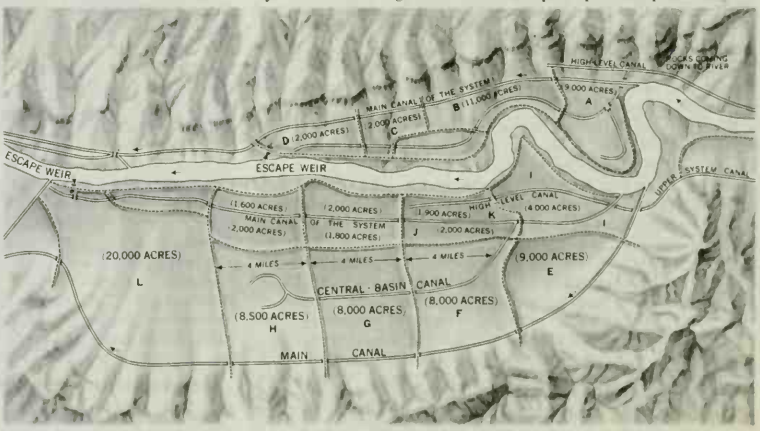

FIG. I.—BASIN SYSTEM OF IRRIGATION. A,B,C,D, FLAT LANDS IRRIGATED BY THE MAIN CANAL; E,I,J,K, LARGE BASINS IRRIGATED BY THE HIGH-LEVEL CANAL; F,G,H,L, BASINS IRRIGATED BY THE CENTRAL-BASIN CANAL

which entitled owners of land adjoining a defined natural watercourse to a reasonably undiminished and unpolluted flow but made little provision for irrigation; and toward giving predominant weight to the principle of beneficial use for the many.

Water is scarce in the western U.S. and serious difficulties have arisen regarding water rights. The arid states, however, enacted comprehensive statutes which enabled most disputes to be adjudicated satisfactorily. In the more humid eastern U.S. the growing use and scarcity of water increasingly drew attention to the urgent need for legislation defining rights to use both surface and underground waters. In the more acute situations, inventories of available water and of the community uses for it were made as a first step toward the complicated public relations, educational efforts and legislation that were needed. In any event, the prospective irrigator should consult competent local authorities and assure himself of a reasonably permanent right to the use of water before undertaking expensive irrigation.

PRINCIPAL SYSTEMS OF IRRIGATION

Basin System.—There are two main forms of irrigation. In the more primitive and inexpensive system the area to be served is surrounded by embankments, and is thus called a basin; into this a canal leads the waters from the river until a depth of three or four feet is attained. Many of these basins are of great size, the largest covering as much as 60,000 ac. The water is run off after a time and the exposed area is sown with crops which need no further watering to bring them to maturity. The system obviously originated in the fact that a river can be easily made to give a supply once a year during its flood period, whereas enormous expense would be required to make it do so at other times. It happens, also, that the production of food crops follows the flood season in many rivers; the system devised, therefore, was one which took advantage of a river's flood season.

Fig. 1, representing a basin system in upper Egypt, will serve to explain this system of irrigation, the firm lines representing canals, the broken lines embankments along the river and between basins. It will be seen, beginning on the east or right bank of the river (top of fig. 1), that a high-level canal flowing, like the river, to the north, from an upper system divides into two. The right branch waters all the desert slopes within its reach. The left branch passes, by a structure, under the main canal of the system, taken from the river close at hand (and therefore at a lower level; see *Canals*, above). This left branch irrigates the high strip of land bordering on the river. In years of very favourable flood, this high-level canal may not be wanted at all; irrigation could be done from the main canal with the great advantage that the main canal water would carry with it much more silt than would be carried from the tail end of the high-level canal which drew its supply from the river perhaps 25 mi. farther upstream. The main canal flows freely over the areas C and D and, if the flood is good, over B and a part of A. It is carried around the next desert point, and to the north becomes the high-level canal. The masonry works required for this system are a structure to pass the high-level canal under the main canal near its head, bridges fitted with sluices where each canal passes through an embankment, and an escape weir at the tail of the system to return the water to the river. The left (west) bank is similarly watered.

Perennial System.—The other modern and expensive system, where a perennial supply of water is made use of, is also fed by canals, but in this case the canal system is enormously developed compared with that of the basin system. In the latter, one canal only may be required to feed many basins by running through the higher-level basins and terminating at the middle of the last one of the series. In the perennial system, branch canals lead off from the main canal, lesser branches lead off from the main branches, and so on in ever decreasing size until as a last branch the smallest runlet is reached. The cost of this canalization is great, but the returns are correspondingly valuable, and usually about two crops can be grown each year instead of the single crop possible with basin irrigation.

Fig. 2 shows a perennial canal system. Only the main canals and principal branches are shown. The main canal may extend over any distance up to 200 mi. or even more. This plan also shows how efficient drainage is provided between the canals. A more detailed canalization from the branches is shown in fig. 3.

OTHER SYSTEMS

Minor Systems.—Dating from Roman times, water meadows in England have been flooded in the wettest and coldest times of the year so that the warmer water might be used as a protection against frost. Warping is an old English practice of flooding land so that the suspended silt may be deposited to form a new topsoil on which crops will be grown under rainfall only.

Subirrigation.—In a few localities water is applied laterally and upward from ditches, drains or pipes located below the surface of the ground. It may result naturally or be installed artificially.

Sewage Farming.—Many towns situated in inland districts, instead of passing their sewage into the nearest stream, deal with it by means of modern settling tank systems, from which the effluent is run off into small canals which irrigate suitable cultivable areas. The yield of crop produced is great, as such waters contain a very high percentage of nitrogenous matter. The drainage of Cairo, Egy., for instance, is said to be 30 times as valuable as the equivalent of Nile water, even in floodtime, when the latter bears its fertilizing silt. Sewage irrigation is not commonly practised in the U.S.

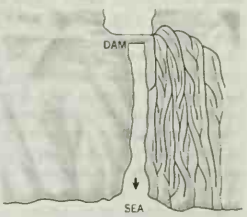

FIG. 2.—DIAGRAM OF IRRIGATION PROPERLY COMBINED WITH DRAINAGE

DRAINAGE

A necessary concomitant to irrigation is drainage of the soil. In few areas does nature provide it adequately without artificial aid. Poor drainage, resulting in excessive salts in the soils, popularly called alkali, has reduced yields in the arid western areas of the U.S. by about 20% and has occasionally caused abandonment of the land, as was often true in ancient countries of the middle and far east. Heavy rainfall in parts of the eastern U.S. and elsewhere causes other difficulties.

For many years the supply of irrigation water was the only problem effectively considered by engineers; the disastrous results which followed in many, if not all, cases from a neglect of the provision of adequate drainage, however, awakened everyone to the necessity of supplying it if optimum moisture control was to be attained, and if fields were to continue fertile in order to raise maximum crops and to utilize longer growing seasons.

Land may be smoothed with proper slopes and ditched so as to remove excess water before it enters the soil and thus prevent erosion, leaching of nutrients and standing pools of water on the surface, and to permit early spring planting. If carefully planned, this smoothing also can prepare the land for surface irrigation, thus serving two purposes by one earth-moving operation. After excess water enters the soil, its removal is an expensive and specialized undertaking that is not directly connected with irrigation, although it sometimes may be necessary for irrigated land. (*See* also LAND RECLAMATION.)

Much of the more promising surface irrigation occurs in humid or semihumid regions where it can be combined with drainage, usually in broad river valleys, alluvial deltas and coastal plains. Huge areas in these regions await this type of development, which, for example, has begun in the 20,000,000 ac. along the lower Mississippi river, where the poorly distributed annual rainfall averages 50 in. Here combined ditching and leveling with heavy

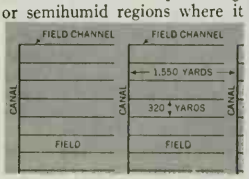

FIG. 3.—PLAN OF FIELD CHANNEL IRRIGATION

grading equipment is little more expensive than for irrigation alone, water supplies are cheap and relatively inexhaustible, expensive flood control and main drainage systems are already installed, the country is settled and large acreages are held under single ownerships that simplify organization, professional management and low-cost mass production under mechanization.

IRRIGATION PRACTICES

Distribution.—Where irrigation is carried on throughout much of the year, as in the perennial system, proper water distribution becomes a most important operation. It is often considered sufficient if during any one season two-thirds of the area commanded is actually supplied with water. This encourages that rotation of crops which seems to be a necessity of good farming, and also the lying fallow for a time of some part of the soil, which also appears to be a necessity in all countries during a portion of each year. Some crops, of course, require water much more often than others; much depends on the temperature at the time of irrigation; and seasons vary from year to year and from place to place. During the winter months in northern India magnificent wheat crops can be produced which have to be watered only two or three times. But to keep sugar cane, indigo or cotton alive in summer before the monsoon begins in India, or the Nile rises in Egypt, the fields should be watered at least once every 15 days, while rice requires an almost constant supply of water. Several irrigations per season are required over much of the United States.

Quantity.—Even if the crops grown under irrigation were in each case identical, in different countries and at different seasons the conditions are so variable as to preclude a statement of volumes of water which would be applicable everywhere. The depth of water applied varies with its purpose, with the climate, season, soil, subsoil, drainage, crop and other factors. Usually, from 2 to 6 in. in depth of water may be given at every one of the several times of watering under the perennial system, whereas the one watering of the basin system may take 30 to 50 in.

Seasonal net requirements of delivered water in the U.S. average from 1 ft. in depth where the effective rainfall is more than 12 in. during the crop-growing season, to as high as 3 ft. where the annual precipitation is less than 10 in., the season long and temperature high.

Measurement.—Various devices have been perfected for accurately measuring the amount of water flowing past a particular point. The rate of flow is usually measured in cubic feet per second (second foot) and the volume in acre feet, that is, 1 ac.ft. being the volume equal to 43,560 cu.ft. required to cover 1 ac. with water 1 ft. deep. A flow of 1 cu.ft. per second will furnish nearly 2 ac.ft. in 24 hours.

By measuring the water, analogously to measuring household water by a meter, it is possible to divide the water equitably among users, charge for the amount delivered and thus conserve scarce and valuable water. Measurement of the volume delivered also enables the irrigator to compute the depth of water that he is applying, a vital fact in attaining maximum production. Only by applying the right amount at the right time can optimum results be secured; otherwise irrigation may be ineffective or even harmful.

Applying the Water.—A proper control of irrigating water can save hard and expensive physical labour, assure uniform and satisfactory results and improve the yield as much as 100% over inefficient methods. Uncontrolled streams of water cause erosion, inefficiency, waste and uneven distribution, and they may even create expensive damage claims. Makeshift devices and procedures may be worse than useless and expert advice is essential. Water is applied to land by flowing it over the surface or by sprinkling from pipes, either method being satisfactory if properly planned and used. The newer sprinkling method predominates in the eastern U.S. and the older surface method in the west.

Experience indicates that a plan for irrigating any field should be chosen so that it will be suitable for different crops, both because of the desirability of rotation and because other crops may become more profitable.

Surface Irrigation.—Where topography and soil are favourable, where skilled irrigators are obtainable, where pumping is unnecessary, where surface drainage would be helpful and where labour and farm equipment are more available than cash, or where many of these conditions exist, surface irrigation may be preferable. Small canals, ditches, flumes or pipes convey the water to the field.

In order that water may flow uniformly and easily over the land, the surface must be reshaped to a suitable slope, only rarely made level. This leveling removes such humps and hollows as would interfere with the flow of water and improves the slope. The type and amount of leveling required is dependent upon the topography, depth and quality of soil, crops to be raised, method of irrigation to be employed and flow of water available. A ground surface free of irregularities permits even distribution of water to the land and crop, a resultant saving in water and labour, and a uniform crop yield. Yields are increased, sometimes as much as 50% to 100%, as a result of leveling. Initial light leveling will nearly always pay in facilitating the distribution of the water in the fields, and usually initial heavy leveling will be advisable, especially for reducing costs on large acreages and where surface drainage is desirable. Efficient equipment is generally available for both light and heavy leveling.

Irrigation water is usually made to flow over the ground through furrows, small ditches or runlets sloping downward between rows of plants; corrugations, which are smaller and closer furrows through closely cultivated plants; flooding, where a shallow sheet of water is confined by small dikes or levees within sloping border strips, contour strips or level basins as it advances over the land; and, less satisfactorily, through wild flooding manually out of ditches without benefit of land preparation and water control as just described. Other surface methods are used occasionally.

Sprinkler Irrigation.—For those not skilled in irrigation and where drainage is unnecessary, overhead sprinkling from pressure pipes, usually with revolving sprinklers and under engineering direction, offers the surest method of applying water. It may be used on most topography without leveling and without experienced irrigators, and, where pumping would be necessary in any event, it may well be the best method. Sprinkling is widely and increasingly used under engineering direction.

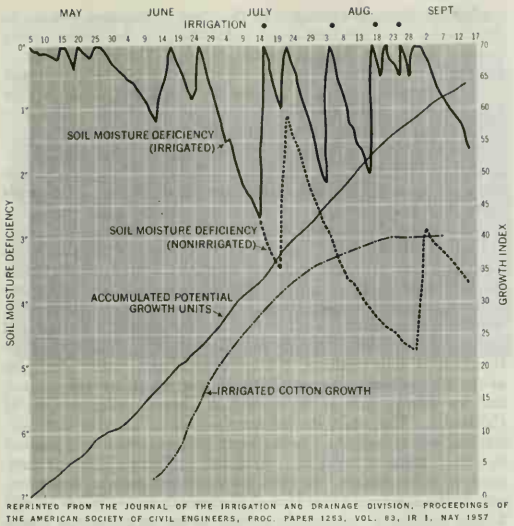
When and How Much to Irrigate.—There are both practical and theoretical approaches to this question, and, in addition, judgment must be developed through local experiment and experience. To get the full value and the best yields from irrigation, the moisture content in the soil must usually be kept well above the wilting point and slightly under the storage capacity of the soil in the root zone. When a crop wilts, irreparable damage usually has occurred. On the other hand, too much water can leach the plant nutrients from the soil, keep air out of the soil and cause erosion.

In the latter 1950s studies, described below, were made to determine the optimum soil-moisture content for specific crops at various stages of growth; they indicate that much better crop yields may become possible under carefully controlled optimum moisture conditions.

Fertilization.—Of the many factors controlling plant growth, two limit growth more often than all of the others combined, namely (1) a lack of adequate moisture control and (2) a lack of ample amounts of the so-called plant foods or plant nutrients. Through irrigation and drainage, farmers can deal satisfactorily with the moisture problem. By the addition of fertilizer (*see* FERTILIZERS AND MANURES), often applied in the irrigation water, they can supply plant foods without which crop production would be limited. This combined use of irrigation, drainage and fertilizer opens up a new frontier for agriculture. Together they present one of the great advances of modern times for growing more and better crops without expanding acreage.

SUPPLEMENTAL IRRIGATION

The older irrigation in the United States was generally developed before the middle of the 20th century by groups of farmers on large projects that by the late 1950s totaled about 28,000,000



REPRINTED FROM THE JOURNAL OF THE IRRIGATION AND DRAINAGE DIVISION, PROCEEDINGS OF THE AMERICAN SOCIETY OF CIVIL ENGINEERS, PROC. PAPER 1253, VOL. 83, IR 1, MAY 1957

FIG. 4.—SOIL MOISTURE DEFICIENCY IN THE SOIL OF THE ROOT ZONE, ACCUMULATED POTENTIAL GROWTH UNITS AND THE ACTUAL GROWTH OF IRRIGATED COTTON. DATES AT WHICH IRRIGATION WAS APPLIED ARE INDICATED BY THE BLACK DOTS AT THE TOP OF THE CHART

ac. west of the 100° meridian, which runs north and south through the centres of the Dakotas, Nebraska and Texas and through the western ends of Kansas and Oklahoma. There the annual rainfall of from 5 to 20 in. is very light during the growing season and heavy irrigation is essential.

On the other hand, supplemental irrigation has been practised mainly since mid-century by individual farmers on much smaller projects totaling by the 1960s about 3,000,000 ac. east of the 100° meridian. There the normal annual rainfall of between 20 and 50 in. is fairly adequate during the growing season and only light irrigation is required, although that small amount produces large returns. Seldom was water added artificially before 1950 except to a limited extent on lawns, golf courses, gardens, rice fields and horticultural crops. However, from 1950 to 1960 in the U.S. about as many acres were brought under eastern supplemental irrigation as were added to the larger and older western total irrigation; moreover, more irrigable land is available in the east than in the west.

As efficient and expensive agriculture developed and as disastrous droughts afflicted much of the humid and semihumid eastern U.S. in the 1950s, this region turned to supplemental irrigation mainly as insurance against droughts. It soon became apparent that added water also increased crop yields in most years, not only during obvious droughts in very bad years, and that even abundant annual rainfall seldom provided enough moisture at all of the times that it was needed. Next it was realized that maximum yields resulted only when the highest type of crop culture was combined with adequate water in the root zone of the soil reservoir at the right time in the growth schedule. Doubling of yields or a return of 100% on the annual cost of supplemental irrigation was not uncommon and it appeared that even larger returns might be anticipated as practices improved. Since supplemental irrigation is expensive in both first cost and operating cost, and since it is quite different from ordinary farming, it must be undertaken and conducted under expert advice. Only when it is accompanied by every modern aid to better agriculture will the best yields be obtained.

Optimum Plant Growth.—Studies in the nearly forgotten science of phenology, the relation of climate to the growth of plants, were undertaken by C. W. Thornthwaite and others, having as their first objective the scientific scheduling of supplemental irrigation and of the crops grown thereunder. Unless supplemental irrigation is applied at the right time and in the right amounts to maintain optimum soil-moisture conditions, it is not only wasted but it may actually be harmful, and crop scheduling is essential to efficient production. Scientific supplemental irrigation requires that both of these practices be utilized. With optimum moisture, scheduling and nutrients provided, actual crop growth can be measured daily and necessary remedial action taken immediately, before permanent injury has occurred, to keep that growth up to its climatic and economic potential, with resulting yields that have seldom been attained in the past.

Fig. 4 shows an actual case relating growth to its potential under an optimum level of soil moisture, a relationship possible only where irrigation is available whenever needed, as, for example, under individual pumping. Where canal water is delivered by rotation many days apart and not in sufficient quantity to fill a badly depleted soil reservoir, as is often the case in the arid west, it may not be possible to maintain the optimum level.

The solid upper curve shows the soil moisture deficiency in the root zone when irrigation is used, and the dotted upper curve shows the deficiency as it would be without irrigation, all plotted downward on the left-hand scale. In this locality the heavy rainfall of 50 in. annually frequently filled the soil reservoir to 0 on the scale. Irrigation was used only four times as shown by the solid dots at the top.

The solid line running upward to the right shows potential growth in this locality, and the dashed lower curve plots the actual measured daily growth of the cotton plants, all plotted upward on the right-hand scale. When actual growth as plotted on this dashed curve began to drop away from potential growth toward the end of July, remedial action should have been taken by irrigating, fertilizing, weeding, pest control or whatever appeared to be necessary. The curves are plotted daily to show when remedial action is necessary, usually several weeks before it becomes apparent on the plants.

The upward potential growth curve and the downward parts of the soil moisture deficiency curve are computed and plotted from evapo-transpiration, which is the moisture being used by the plants and being evaporated into the atmosphere (*see* DROUGHT).

IRRIGATION THROUGHOUT THE WORLD

World Survey.—As the second half of the 20th century was well under way, the total irrigated acreage of the world had nearly tripled since 1900. The largest acreages were credited to China, India, the United States, the U.S.S.R. and Pakistan. The total for all countries was about 320,000,000 ac., as compared with a total of about 110,000,000 ac. in 1900.

A general idea of the nature and expansion of modern irrigation and associated water control throughout the world was indicated

BY COURTESY OF AUSTRALIAN NEWS AND INFORMATION BUREAU

FIG. 5.—FARMS ALONG A MAIN CHANNEL OF THE MURRUMBIDGEE IRRIGATION AREA, NEW SOUTH WALES, AUSTR.

by a few of the plans and accomplishments in the late 1950s. The government of Communist China announced readiness to start construction on the first and largest of the 46 dams projected to control the floods of the Yellow river, produce electric power far in excess of the previous total and greatly increase the irrigated acreage. Formosa (Taiwan) and South Korea were modernizing and increasing their irrigated land area by several per cent annually. There, and throughout much of the far east, large rice acreages limited to one crop annually would be able to grow two crops annually when additions to their water supply were secured. India completed Hirakud dam on the Mahanadi river in the state of Orissa (1957), creating a storage capacity of more than 6,500,000 ac.ft. and permitting the eventual irrigation of about 670,000 ac. The project, entirely an Indian engineering effort, was begun in 1948. India's five-year plans included programs to increase the total irrigated area from 51,500,000 ac. in 1951 to more than 70,000,000 ac. in the 1960s. In Pakistan, construction was well along on the Warsak dam, planned to generate 240,000 kw. of electricity and effect the irrigation of 120,000 ac. India and Pakistan signed the Indus Waters treaty in 1960, and construction of dams, including the key Jhelum river dam, canals and other works was begun with aid from the World bank (International Bank for Reconstruction and Development). In the Rechna Doab project in West Pakistan, tube (drilled) wells were installed to create favourable drainage by lowering the water table, while providing water for irrigation.

U.P.I. COMPIX

FIG. 6.—FARMERS OF THE DAMODAR VALLEY, INDIA, AT WORK IN FIELDS FLOODED BY THE REGION'S CANALS

Spain's effort to restore productivity to the Guadiana river valley and provide electricity for Madrid had brought about the irrigation of about 33,000 ac. of an expected ultimate 300,000 ac. Work was also started to use the Ebro river for the early irrigation of about 250,000 ac. and eventual service to 2,500,000 ac. In Portugal the Mira river scheme was planned to irrigate 30,000 ac. in citrus, vegetables and cereals; since 1937 nearly 300,000 ac. had been brought under irrigation in government schemes and more than 600,000 ac. in private projects. Australia opened the Eildon reservoir to create an irrigation storage capacity of 2,750,000 ac.ft. of water near the source of the Goulburn river in the province of Victoria. Work continued in the 1960s on the Snowy Mountains project begun in 1950. Venezuela completed the nine-mile long earth dam on the Guárico river, expected to bring about the irrigation of 272,000 ac. of pasture and forage land. In Mexico the acreage irrigated by government projects increased by more than 100% between 1950 and 1960, from 3,000,000 ac. to 6,700,000 ac.; crops from this land were estimated to represent 33% of the total value of agricultural production.

In Italy the Flumendosa project was planned to effect the irrigation of 123,500 ac. in the Campidano di Cagliari, a plain in southwestern Sardinia, by three dams on the Flumendosa river and its tributaries, with connecting tunnels and irrigation distributaries. The most important feature of a four-year program in Japan was the proposed irrigation of 42,000 ac. already under paddy and 40,000 upland acres in the Aichi region on the island of Honshu. This was reported as the nation's first attempt to irrigate ridge lands. Among the several objectives of the Bhumiphol project in Thailand was the provision of additional water for the irrigation of more than 2,000,000 ac. in the area served by a large new system in the Chao Phraya river basin.

Considerable progress has been made in Africa, for example, on the Aswan high dam project. The Nile Waters agreement (1959) between Egypt and Sudan made necessary the construction of Roseires dam, in Sudan, for water storage. Related projects included the Managil extension to the Gezira irrigation system to increase by 75% the land under cultivation by the Sudan Gezira board. (*See* also NILE; AFRICA: *Natural Resources: Water.*) In Southern Rhodesia, Kyle dam was opened in 1961 as part of the Sabi-Lundi basin project to irrigate more than 300,000 ac. of low veld formerly devoted to ranching. The project was planned to greatly expand cotton, citrus and sugar acreage.

Both total and supplemental irrigation are being rapidly extended and improved by governments throughout the world in a scientific manner that will ensure greatly increased crop yields by modern procedures.

See also articles on various countries.

United States.—Perhaps the most efficient development of irrigation may be found and studied in the United States. In a single year of the late 1950s, the United States bureau of reclamation announced a construction program that, upon completion, would provide water for 150,000 ac. not previously irrigated and additional supplies for 94,000 ac. Contracts were let for the construction of main features of Glen canyon dam, major structure of the comprehensive upper Colorado river basin storage project, and for Trinity dam in the expanding Central valley project of California. That state started construction of Oroville dam, initial and key unit of the Feather river project, which was planned to serve extensive areas in central and southern California hundreds of miles distant. Beyond the foregoing western expansion, and in the same year, the United States soil conservation service helped to place a comparable acreage under supplemental irrigation in eastern U.S.

Relatively small areas in the southwestern portion of the country were irrigated in prehistoric times. The customs and methods used were improved by the Spanish conquerors and their descendants. Modern irrigation in the U.S. west began with the arrival of the Mormons in Utah in 1847 and increased to about 31,000,000 ac. early in the second half of the 20th century. Taking into consideration the available land and the availability of water supplies of reasonable cost, it was estimated that about 20,000,000 ac. more of western land could be developed by irrigation and perhaps another inadequately supplied 10,000,000 ac. could be furnished with additional water. In the humid eastern U.S. it was felt that an equally large acreage might be brought under supplemental irrigation, as described above.

Irrigation development in the United States followed a natural course concurrent and interwoven with the settlement and development of the west. The first works were simple ditches built by the settlers for diverting water from streams to easily reached farm lands in the valleys near by. These settlers were not financially able to build costly works, and common practice involved the use of wood and temporary structures.

In course of time, however, many land and water corporations were formed, with the aid of invested capital, for the purpose of exploiting the agricultural resources of the west. There followed legislative action by the states to enlarge the powers of farmers' organizations, enabling them to bond their land and raise funds for building, purchasing and reconstructing irrigation systems. In 1902 congress passed the Reclamation act, by which the federal government became an active participant in irrigation work. These agencies employed experienced engineers and designed and constructed more extensive and permanent irrigation works. The work of building new systems and remodeling and reconstructing existing enterprises continued, and the makeshifts of earlier periods were generally replaced by substantial structures of concrete and steel.

A degree of efficiency and permanence was attained in irrigation systems comparing favourably with those of any other country. The original Reclamation act was revised and greatly enlarged in scope, and under it the U.S. reclamation service and its successor, the bureau of reclamation (est. 1923), built many of the world's largest irrigation structures. It investigated and planned a comprehensive development of all the available water resources of the western states for their optimum utilization for irrigation and related purposes in large integrated basin-wide projects involving many large storage reservoirs, transmountain diversions, etc. In

co-operation with the U.S. army corps of engineers, it continued to investigate and report on the comprehensive use of water resources for the arid west and to aid in construction and operation. The U.S. soil conservation service promoted irrigation in the humid east.

The United States was believed to rank first in the number, dimensions and permanency of its dams for storage of irrigation water; in the efficiency of mechanical equipment used to pump and control water for irrigation; in the efficiency of works to convey water to and distribute it on farms; and in scientific agricultural applications.

Chemical and agricultural science, mechanization, agricultural education and mass production for special markets under professional management combined to bring about a very efficient agriculture which was correspondingly expensive; while governmental aids tended to support prices at only modest levels, if at all. Under these conditions farmers seldom can afford to spend the larger production costs without having adequate, even if expensive, irrigation water to assure a good crop.

The necessity of these expensive aids for profitable modern agriculture established a trend toward increased acreage under a single management in order to secure low-cost agricultural mass production analogous to large-unit industrial mass production. Costly irrigation and drainage accentuated this trend and made it increasingly difficult for the traditional small family farm unit of the U.S. to furnish a satisfactory living for the family. There were, indeed, exceptions under special conditions, when a single-family farm unit might be very efficient. Various types of farm organization were being studied with a view to increasing the acreage irrigated under a single management. Historically, irrigation has always forced individuals to organize into larger groups with larger investments and better management. It continued to play this important role.

(H. RY.)

IRTYSH, a river of the U.S.S.R., flows through western Siberia and Kazakhstan and traverses the East Kazakhstan, Semipalatinsk and Pavlodar *oblasts* of the Kazakh Soviet Socialist Republic and the Omsk and Tyumen *oblasts* of the Russian Soviet Federated Socialist Republic. It is the principal tributary of the Ob river and rises in the glaciers on the southwestern slopes of the Mongolian Altai (in Sinkiang, China). Until it flows into Lake Zaisan it is called the Cherny Irtysh (Black Irtysh). Its total length is 2,760 mi., almost wholly navigable. From Lake Zaisan the river flows for a distance of 70 mi. (as far as the Kurchum river) through a monotonous steppe, its banks being low and covered with reeds. After being joined by the Narym river, the Irtysh traverses the western edge of the Altai, flowing through a narrow valley, the narrowest part of which lies between the mouth of the Bukhtarma and the town of Ust-Kamenogorsk. The channel of the river there is stony and in places the banks are precipitous. Lower down the Irtysh is joined by the Ulba and Uba rivers. From Semipalatinsk to Omsk (625 mi.) the Irtysh receives no considerable tributaries. Its banks in this sector are generally low and sandy, and the channel is often broken by islands. The valley there is about 6 to 7 mi. wide. A little above Omsk the Irtysh emerges from steppe into forest country and later into the taiga zone. From Omsk to Tobolsk the river receives several tributaries. The banks are sandy and the right bank is usually higher than the left. The width of the valley is about 3 mi. After receiving the Tobol tributary the water capacity of the Irtysh increases greatly. It joins the Ob near Khanty-Mansisk. The width of the valley from Tobolsk to the river mouth is about 7 mi. and at the actual confluence is nearly 20 mi. In the lower reaches the largest tributaries are the Ishim, Tobol, Vagai and Konda on the left, and the Om, Tara and Demyanka on the right. In its upper course the Irtysh receives its water from the mountain snows and glaciers, and in the lower course from snow and subsoil water; rainfall accounts for only a small part. The volume of water varies considerably from year to year. At Omsk the average annual discharge of water amounts to 933 cu.m. (32,946 cu.ft.) per second, while at Tobolsk it is 2,240 cu.m. per second. The Irtysh abounds in fish, those of industrial importance being sturgeon, sterlet, burbot, ide and bream.

There are many important mineral deposits in the Irtysh basin, particularly in the Altai. In the Pavlodar region is the Ekibastuz coal field. In the middle course there are many salt lakes. There too is much cultivation of wheat, and milk and meat are produced in large quantities. The Ust-Kamenogorsk hydroelectric station was completed in 1953 and that at Bukhtarma was constructed under the seven-year plan (1959–65). Steamers, carrying mainly timber, grain and coal, ply regularly from Malokrasnoyarka to the mouth of the Ob river (*c.* 2,000 mi.). The main river ports are Khanty-Mansisk, Tobolsk, Tara, Omsk, Pavlodar, Semipalatinsk and Ust-Kamenogorsk. (G. E. WR.)

IRVINE, a royal and small burgh and seaport of Ayrshire, Scot., standing on the Irvine river, which with the Annick runs into the Garnock estuary; it is 8 mi. W. of Kilmarnock. Pop. (1961) 16,911. Alexander II granted it a charter which was confirmed by Robert Bruce in 1322. About the end of the 17th century it was reckoned the third shipping port in Scotland, but its importance declined, partly because of the partial silting of the harbour and partly because of the establishment of harbours at Ardrossan and Troon. Now mostly coastal shipping uses the harbour. The academy is a pre-Reformation foundation. While the town is essentially industrial, it lies in the centre of golfing country, there being two first-class golf courses on the northern boundary—Bogside and Irvine municipal—and the well-known Gailes and Barassie golf courses on the southern boundary. Industries include ship repairing, the manufacture of cold-formed metal sections, iron and brass founding, saw milling, and pipe manufacture; there are also factories making hosiery, chemicals, bottles and horn products. The principal exports are bricks, tar, cement, fireclay goods, pipes, gravel and sand; imports include timber, limestone and cement.

IRVING, the name of a family of English actors.

SIR HENRY IRVING (1838–1905), the most famous English actor after David Garrick, was the son of Samuel and Mary Brodribb and was born at Keinton Mandeville, Somerset, on Feb. 6, 1838, being christened John Henry. As a youth he was employed as a clerk in the City of London, but in 1856 he decided to be an

actor, taking the name of Henry Irving. His first appearance was at the Royal Lyceum theatre, Sunderland, as Gaston, duke of Orleans, in Bulwer-Lytton's *Richelieu*. For ten years he played in provincial stock companies, acting more than 500 parts. In 1866 he was engaged by Dion Boucicault to play in Manchester the leading part, Rawdon Scudamore, in *The Two Lives of Mary Leigh*, which later, retitled *Hunted Down*, was transferred to the St. James's theatre, London. This led to Irving's engagement by Alfred Wigan at the newly opened Queen's theatre, and in 1870 he made his first conspicuous success as Digby Grant in James Albery's *Two Roses* at the Vaudeville. His performance in this part and, on the night of his benefit, his dynamic recitation of Thomas Hood's *The Dream of Eugene Aram* inspired Hezekiah Bateman, the American impresario, to engage him as leading man at the Lyceum theatre. Bateman's enterprise was a failure until he allowed Irving to produce and to play the leading part of Mathias in *The Bells*, a version of Erckmann-Chatrian's *Le Juif Polonais* by Leopold Lewis. Irving's success as Mathias was immediate and sustained; the play ran for 150 nights and remained a feature of his repertory until his death in 1905. Irving, after playing the title role in W. G. Wills's *Charles I* and *Eugene Aram*, and in *Richelieu*, made in 1874 a bid for supremacy as an actor by appearing as Hamlet. The humanity and distinction of his performance won him public acknowledgment as the leader of his profession, and the play had an unprecedented run of 200 nights. When Bateman died in 1875, Irving, under the management of Mrs. Bateman, continued to play in partnership with her daughter Isabel until 1877, appearing successively in Shakespearean tragedy and contemporary plays.

In 1878 Irving became lessee and manager of the Lyceum. With Ellen Terry (*q.v.*) as Ophelia and Portia, he revived *Hamlet* and produced *The Merchant of Venice* (1879). His Shylock was as controversial as his Hamlet, the dignity with which he invested the Jew pleasing some as much as it offended others. The play became a mainstay of his repertory; he declared toward the end of his career "in all humility . . . mine is the only great Shylock." After the production of Tennyson's *The Cup*, he invited Edwin Booth (*q.v.*) to play with him at the Lyceum, the English and American actors alternating in the parts of Othello and Iago. Irving's brilliantly conceived Iago was highly praised; his Othello, which lacked physical force, comparatively failed. In 1882–83 Irving and Ellen Terry had their greatest Shakespearean success in *Much Ado About Nothing*. Later in the year, Irving paid the first of several visits to the United States with the whole Lyceum company and with the scenic and lighting effects for which his theatre was famous. He continued in management of the Lyceum until 1899, producing *Twelfth Night* (1884), *Olivia* (a dramatization by Wills of Goldsmith's *Vicar of Wakefield;* 1885), *Faust* (1886), *Macbeth* (1888), *The Dead Heart* (1889) and *Ravenswood* (1890). In 1892 Irving's performance of Wolsey in *Henry VIII* was acclaimed, and in 1893 he produced Tennyson's *Becket*, in which, as the archbishop, he made a deep impression upon his audiences. Further productions, such as *King Arthur* and *Don Quixote* (1895), *Cymbeline* and *Richard III*, one of his most striking interpretations (1896), and *Peter the Great* (1898), did not meet increasing costs. In 1899 ill-health and misfortunes, which included the destruction by fire of almost all his stocks of scenery, induced him to surrender his control of the Lyceum to a limited liability company. In 1902 the company went into liquidation and Irving's reign at the Lyceum ended. His farewell season at Drury Lane in 1905, however, showed that his powers as an actor and his popularity with the public were undimmed. On Oct. 13 of that year he died, shortly after playing Becket at the Theatre Royal in Bradford. He was buried in Westminster abbey.

Both on and off the stage Irving maintained a high ideal of his profession. In 1895 he received the honour of knighthood, the first ever accorded an actor. His acting, apart from his genius as a stage director, divided criticism, opinions differing as to whether his mannerisms of voice and deportment hindered or helped the expression of his ideas. He excelled in the portrayal of fear, horror, scorn or malignity. A commanding personality such as his was bound to colour whatever part he assumed, but the richness and originality of this colouring were as admirable as the intellect and imagination with which his interpretations were conceived.

In 1869 Irving married Florence O'Callaghan, but after the birth of their two sons, Henry Brodribb and Laurence Sidney Brodribb, Irving and his wife were legally separated.

Henry Brodribb Irving (1870–1919), elder son of Sir Henry Irving, was born in London on Aug. 5, 1870. He was educated at Marlborough and at New college, Oxford, where he joined the Oxford University Dramatic society. He was called to the bar in 1894 but soon abandoned a legal career for the stage. His first appearance in London was made in Sept. 1891 with John Hare at the Garrick theatre in T. W. Robertson's *School*. In 1894 he joined Ben Greet's company, where he met Dorothea Baird, whom he married in 1896. His first notable success was in Barrie's *The Admirable Crichton* (1902–03). In 1905 he appeared as Hamlet at the Adelphi theatre, where his scholarly and vital performance established him as a creative actor of distinction. Forming his own company, he produced a successful version of Robert Louis Stevenson's *Dr. Jekyll and Mr. Hyde* and Stephen Phillips' *The Sin of David*. He was lessee and manager of the Savoy theatre from 1913 until his death in London on Oct. 17, 1919. Irving was a keen student of criminology and published *The Life of Judge Jeffreys* (1898), *French Criminals of the Nineteenth Century* (1901), *A Book of Remarkable Criminals* (1918) and *Last Studies in Criminology* (1921).

Laurence Sidney Brodribb Irving (1871–1914), younger brother of Henry Brodribb Irving, was born in London on Dec. 21, 1871. He was educated at Marlborough and, to enter the diplomatic service, studied for three years in St. Petersburg, but financial stringency prevented him from fulfilling this intention. Returning to England in 1893, he began his career as an actor in Frank Benson's Shakespearean company. In 1894 he made his first important appearance in London in Barrie's *Walker, London*. He married the actress Mabel Hackney and with her presented foreign plays of distinction to English audiences, notably *The Three Daughters of M. Dupont*, his own dramatization of Dostoevski's *Crime and Punishment* and M. Lengyel's *Typhoon*. In the last play (1912) he revealed himself as an actor of genius, which his brief appearances as Iago and as the Earl Skule in *The Pretenders* by Ibsen later in that year confirmed. In 1914 he took his company to Canada and was returning thence when he and his wife lost their lives in the sinking of the "Empress of Ireland" on May 28, 1914.

Laurence Irving wrote several plays, including *Peter the Great, Bonnie Dundee* and *Richard Lovelace*. His scholarship, allied to his unusual sensitivity, enabled him as an actor to portray with remarkable integrity the manners and characteristics of foreign peoples.

IRVING, EDWARD (1792–1834), minister of the Church of Scotland, famous preacher closely associated with the formation of the Catholic Apostolic Church (*q.v.*), was born at Annan, Dumfries, on Aug. 4, 1792, and studied at Edinburgh university. After several years as a teacher he was called in 1822 to the Caledonian chapel in London where his congregation grew so large that in 1827 a new church was built in Regent square.

The eschatological emphasis in Irving's preaching gradually lessened his popularity, and in 1828 his orthodoxy was challenged. Two great themes had come to dominate his thoughts—his understanding of the incarnation of Jesus Christ and his growing expectation of the second coming. In 1828 Irving published a volume of sermons called *The Doctrine of the Incarnation Opened* which aroused a storm of controversy. In 1830 he brought out a further volume, *The Orthodox and Catholic Doctrine of Our Lord's Human Nature*. It also aroused violent opposition and Irving was

charged in ecclesiastical courts with holding "the sinfulness of Christ's humanity." Irving himself maintained that the charge was unjust, being based on a misinterpretation of his words. He was excommunicated by the London presbytery and in 1833 condemned and deposed from the ministry of the Church of Scotland by the presbytery of Annan. From this time he traveled throughout the country, preaching where he could, until he returned to London, where he was accorded a minor position in the evolving Catholic Apostolic Church. He died in Glasgow on Dec. 7, 1834, and is buried in the crypt of Glasgow cathedral.

Among Irving's closest friends were Thomas Carlyle, Charles Lamb and Samuel Taylor Coleridge. From 1826 he was a member of the Albury conferences, led by Henry Drummond, for the study of unfulfilled prophecy. About 800 from his Regent square congregation, influenced by Irving's belief in the catholicity of his teaching and the continuance of the apostolic order of the church, formed the Catholic Apostolic Church, the first edition of whose office and liturgy was issued from Albury shortly after his death.

Irving's sermons and lectures and his collected writings, edited by G. Carlyle, were published in 1864 and 1865 respectively.

IRVING, WASHINGTON (1783–1859), U.S. writer, is variously called "first American man of letters," "dean" or "father of American literature," and "inventor of the short story." Much of the praise bestowed on him was deserved; some of it was owing primarily to his having been "first." Intellectually, Irving was a lesser man than many of his predecessors. He lacked the religious intensity of Mather, the philosophical acumen of Edwards, the versatility of Franklin, the statesmanship of Jefferson or the dedication of Paine. Yet he outlives them all in the history of American letters. His greatest literary success was won with *The Sketch Book* in 1819—precisely at the moment when British-American animosity had reached a new high—as if in answer to Sidney Smith's contemptuous query, "In all the four quarters of the globe, who reads an American book?" It was a book which all the world, especially many Englishmen, read with delight. While it gave little evidence that Irving was a man of great ideas, emotional depth or imaginative power, it established him as a talented writer, possessed of a temperament and a style, which he combined and varied deftly from sentiment and romance to wit and urbanity in ways to leave no doubt that here at last was an American whose elegant good taste was instinctive. Far from a bumptious provincial, he was a cosmopolite, speaking a language universally recognized in cultivated circles.

Irving was born in New York city on April 3, 1783, and in the attainment of the graces of living was conditioned by his rearing. The favourite and last of 11 children of an austere Presbyterian father and a more genially minded Anglican mother, young Irving grew up in an atmosphere of indulgence. A disposition toward frailty and sensitivity got for him the best that family competence and brotherly favouritism could supply. He escaped the regularity of a college education which his father required of his older sons, but because it was still customary for a gentleman to have a profession, even though he might not practice it, he read intermittently at the law, notably in the office of Josiah Ogden Hoffman, with whose pretty daughter Matilda he early fell in love. His "inveterate enemies, the fathers of the law," did not prevent his participation, as a gay-young-man-about-town, in the social whirl of the city or his association with young men bent, like himself, on enjoying life in terms of feminine society, theatrical entertainment and literary amusement. Associations of this kind led to his writing a series of whimsically satirical essays over the signature of "Jonathan Oldstyle, Gent.," published in Peter Irving's paper, the *Morning Chronicle*, during 1802–03. This youthful playing with the pen was interrupted by several trips up the Hudson, another into Canada in the interest of his health, and, during 1804–06, an extended tour of Europe, during which his health improved markedly, his manners were given a brush and several notebooks were filled with experiences picked up in a constant round of sight-seeing, flirtatious pleasantries and frivolous entertainment.

On his return, he passed the bar examination late in 1806 "by the grace of God and Josiah Hoffman," his tutor and chief examiner; and soon thereafter he set up as a lawyer by moving into his brother John's office at No. 3 Wall street. But his pursuit of this profession was desultory. During 1807–08 his chief occupation was to collaborate with his brother William and James K. Paulding in the writing of a series of 20 periodical essays entitled *Salmagundi*. To secure variety, they followed the Addisonian scheme of having the several subjects treated by several quaint gentlemen, each reminiscent of members of the Spectator club. They posed as "critics, amateurs, dilettanti, and cognoscenti" and proceeded, in true *Spectator* fashion, "to instruct the young, reform the old, correct the town, and castigate the age." They went on merrily, moralizing seldom, content to take "the world as it goes," yet gently satirizing the ways of the fashionable world, ridiculing the pretensions of political upstarts and social climbers, inserting squibs on the theatre, waging war against boorishness and mediocrity, "folly and stupidity," while teaching "parents how to govern their children, girls how to get husbands, and old maids how to do without them." Occasionally they mixed in a little pointed satire of Jefferson, his "rabble republican" followers and the "logocratic" democracy they sought to institute. *Salmagundi* made an impression, and became a mild terror in certain quarters of the town. While concerned primarily with passing phases of contemporary society, the essays retain significance as an index to the social milieu in which the Federalistically indoctrinated young men moved so easily.

His next book, *Diedrich Knickerbocker's History of New York* (1809), was planned merely as a parody of Samuel Mitchell's pretentious guidebook to New York city, but was eventually expanded into a comic history of the Dutch regime in New York, prefaced by a mock-pedantic account of the world from creation onward. Like *Salmagundi*, it embodies a great deal of contemporary social and political satire, born of youthful exuberance and effrontery.

The composition of this "first great book of comic literature written by an American" was interrupted in April 1809 by the sudden death of Matilda Hoffman. Grief incapacitated him for a while; but in the end the hard work necessary to complete *Knickerbocker*, the success of the book and his transfer in 1811 to the newer and wider scene of Washington as a lobbyist in the interests of the Irving brothers' hardware-importing firm helped transmute his grief into the realm of memory. His life, however, seemed to him more or less aimless for some years more, during which he turned to a variety of pursuits. He prepared an American edition of Thomas Campbell's poems, edited the *Analectic Magazine* and acquired a staff colonelcy during the War of 1812. In 1815, when his brothers' business (in which he had been a nonparticipating but profit-sharing member) declined, he sailed for Europe to look after the firm's interests in Liverpool, only to find that his efforts were not enough to stave off bankruptcy. What turned out more profitable in the end were the literary associations that he formed in London, and more especially a visit to Sir Walter Scott, who encouraged and stimulated him to renewed effort. The result was *The Sketch Book of Geoffrey Crayon, Gent.* (1819–20).

A true sketch book, miscellaneous and uneven, a composite of sentiment and romance, satire and whimsicality, fact and fiction, old and new world—its thirty-odd pieces include the first three so-called modern short stories ("The Legend of Sleepy Hollow," "Rip Van Winkle" and "The Spectre Bridegroom") and an essay, "English Writers on America," in which Irving spoke sane, abiding and forthright words on the nonsensical controversy which kept the British and the Americans in a bad humour with each other. The tremendous success of the book assured Irving, now reliant on his own resources, that he could live by his pen, and two years later he produced *Bracebridge Hall*, a sequel as it were to *The Sketch Book*. When critics pointed out literary borrowings and refurbishings of old tales in these two books, Irving set upon a studied search for novelty. Aware that his mind was not truly creative but rather receptive—that it needed some outside stimulation, such as travel, new associations, or old tales and anecdotes

might provide—he resolved: "I shall occasionally shift my residence and write whatever is suggested by objects before me." Hence he traveled in Germany, Austria, France, Spain, the British Isles and later in his own country; his pictures are the transcriptions of an antiquary rather than the conceptions of a creator.

Seeking better health and expecting to exploit the wealth of German folklore, Irving went to Germany, where during the winter of 1822–23 (spent mainly in Dresden) he gathered the materials for a "German sketch book," *Tales of a Traveller* (1824). This proved to be little more than a hodgepodge of travel reminiscences and badly assimilated ragtags of legendary lore, which the critics attacked savagely. Next he turned to Paris, where he collaborated in various dramatic and operatic productions, notably with John Howard Payne; and early in 1826 he accepted the invitation of Alexander H. Everett, then chargé d'affaires in Madrid, to attach himself to the American legation in Spain and there to translate M. F. de Navarrete's recent book on Columbus. Instead, he chose to produce his own *Columbus* (1828), followed by *The Companions of Columbus* (1831). Although both have long been superseded by later researches, they still supply readers with the essentials of Columbus' romantic life and exploits. Meanwhile Irving had become absorbed in the legends of Granada and of the Moorish past, and residence in the old Alhambra provided a fit setting for the composition of his *Conquest of Granada* (1829) and *The Alhambra* (1832), the latter the Spanish counterpart of *The Sketch Book*.

After 17 years' absence, Irving returned to New York in 1832, where he was warmly received. Impressed by the opening of the western frontier, he made an adventuresome journey west and produced in rapid succession *A Tour of the Prairies* (1835), *Astoria* (1836) and *The Adventures of Captain Bonneville* (1837). Except for four years (1842–1846) of distinguished service as minister to Spain, Irving spent the remainder of his life at his home "Sunnyside" on the Hudson, surrounded and revered by friends and relatives, and devoted to literary pursuits, chiefly biographical: *Oliver Goldsmith* (1849), *Mahomet and His Successors* (1850) and a five-volume life of his namesake, *George Washington* (1855–1859). He died on Nov. 28, 1859.

IRVING, a city of central Dallas county, Tex., U.S., a residential community west of Dallas (*q.v.*) and within its metropolitan area. The townsites Kit and Gorbett preceded Irving, but when the Rock Island railroad shifted its proposed route the present location of Irving was determined in 1902 by Otis Brown and J. O. Schulze. Irving's population increased rapidly after 1950; for comparative population figures *see* table in TEXAS: *Population*. (E. C. BE.)

IRVINGTON, a city in Essex and Union counties, N.J., U.S., bordering Newark and 10 mi. W. of New York city in the Newark standard metropolitan statistical area. Pop. (1960) 59,379. (For comparative population figures *see* table in NEW JERSEY: *Population*.) It is highly industrialized; products manufactured there include foods, machinery, jewelry, toy electric trains, paints, electronics, plastics, tools and castings. The city has several parks and playgrounds, a large library, a hospital and many national club organizations.

The area was settled in the 1690s and was a part of Newark. By 1812 it became an independent township, called Camptown; this name was changed in 1852 to Irvington in honour of the writer Washington Irving. The city was incorporated in 1898. In its early history it was noted for its shipbuilding, its horse racing and its position, after 1802, as a relay station for the New York-Philadelphia stagecoach run. (W. L. CA.)

ISAAC, the second of the fathers of Israel (*q.v.*), was the only son of Abraham (*q.v.*) by Sarah, and the father of Esau and Jacob (*q.v.*). The biblical etymology of Isaac, "he laughs," is connected with the circumstances of his birth (Gen. xvii, 15 ff.). The episodes reported of Isaac are strangely similar to episodes in the Abraham story. He is associated with sites in the south of Palestine, Beer-lahai-roi (xxiv, 62) and Beersheba (xxvi, 23). Vague and scanty as his story may be, Isaac is nonetheless the child in whom God's promise to Abraham is kept, and he in turn becomes the vehicle of the promise (Gen. xxvi, 24; Rom. ix, 7; Gal. iv, 28). In the Old Testament, in Judaism and in the New Testament God is called the God of Abraham, Isaac and Jacob, because with them God's relationship of promise and purpose was fixed for all those who descend from them (Ex. iii, 6; Matt. xxii, 32). The story of Abraham's sacrifice of Isaac was used in the early church as an example of faith (Heb. xi, 17) and obedience (James ii, 21), and as a type of the sacrifice of Christ (Barnabas 7); and in later Jewish tradition the sacrifice of Isaac is cited in appeals for the mercy of God, much as the cross of Christ was used in the church. (J. L. MA.)

ISAAC I (ISAAC COMNENUS) (*c.* 1005–1061), Byzantine emperor from 1057 to 1059, was the son of an officer of Basil II named Manuel Comnenus, who on his deathbed commended his two sons Isaac and John to the emperor's care. Basil had them educated at the monastery of Studius in Constantinople and advanced them to high official positions. During the reigns of Basil's successors, Isaac by his prudent conduct won the confidence of the army; in 1057 he was one of the Asian military magnates who overthrew Michael VI, and after the latter's deposition was invested with the crown, thus founding the new dynasty of the Comneni.

Isaac made some attempt to propitiate the defeated civil aristocracy by conferring office on Michael Psellus and Constantine Lichudes. But his radical opposition to the policy of this party is seen in his stringent financial economies. He even confiscated ecclesiastical property. He came into conflict with the arrogant patriarch Michael Cerularius, whose challenge to the traditional interdependence of church and state was met by a demand for his resignation. Cerularius refused; he was then sent into exile by Isaac in Nov. 1058 and was called upon to stand his trial for treason and alleged heresy, but he died before this took place. This episode added to Isaac's unpopularity with the people and the church; he also had to face the opposition of the displaced civil party. His only military expedition was against the Hungarians and Pechenegs (Patzinaks), who began to ravage the northern frontiers in 1059. Shortly after this successful campaign he was seized with an illness and, believing it to be mortal, was persuaded to appoint as his successor Constantine X Ducas, to the exclusion of his own brother John. Although he recovered, Isaac did not resume the purple but retired to the monastery of Studius and spent the remaining two years of his life as a monk there, alternating menial offices with literary studies.

As one of the military aristocracy, Isaac aimed at restoring a sound financial economy at home and building up the neglected military defenses of the empire. His somewhat high-handed methods were unpopular with the civil aristocracy and the clergy and not understood by the people.

ISAAC II (ISAAC ANGELUS) (*c.* 1155–1204), Byzantine emperor from 1185 to 1195 and again from 1203 to 1204, was unexpectedly acclaimed by the mob in Constantinople who murdered Andronicus I (*q.v.*) Comnenus. His reign was inaugurated by the decisive victory of his general Alexius Branas over the Normans, who after invading the empire and sacking Thessalonica (1185) were now driven off Greek soil, except for the islands of Cephalonia and Zacynthus (Zante). He concluded a treaty with Bela III of Hungary and married his daughter Margaret. But he failed in an attempt to recover Cyprus from the rebel Isaac Comnenus. Nor could he quell the rising of the Bulgarians and Walachians under Peter and Asen that broke out toward the end of 1185, though he himself led the campaigns against them, and in 1187 he recognized the second Bulgarian empire. In 1189 Isaac was faced with the third crusade, and Frederick I Barbarossa, who took the land route

through the Balkans and Byzantine territory, proved an implacable enemy. Frederick conspired with the Serbs and Bulgars and also with the sultan of Iconium against the Byzantine emperor, who had tried to protect himself by a treaty with Saladin. Isaac, however, was forced to assist Frederick, who otherwise threatened to capture Constantinople, and in 1190 he concluded the treaty of Adrianople with him, promising transport and provisions. Once Frederick had left for Asia Minor, Isaac turned his attention to the Balkans, where he defeated Stephen Nemanya of Serbia in 1190 and concluded a marriage alliance with him. But he was unsuccessful in campaigns against Bulgaria. With Hungarian help, he was about to embark on a further expedition against the Bulgarians when he was blinded by his brother Alexius, who was then recognized emperor (April 1195). After eight years' imprisonment Isaac, though little more than a figurehead, was once more raised to the throne in July 1203 (*see* CRUSADES) and reigned together with his son Alexius IV (*q.v.*). But in Jan. 1204 he was again deposed, this time by his general Alexius V (*q.v.*) Ducas Murtzuphlus, and died shortly afterward. Although he was incapable of stemming administrative abuses, Isaac before he was blinded was not a feeble nonentity, as often implied; he did make some attempt to hold his own against Frederick I Barbarossa and to retrieve imperial fortunes in the Balkans.

ISAAC OF ANTIOCH (called THE GREAT) is the name used to distinguish Isaac of Amida, a 5th-century Syriac writer, from two Edessene Isaacs, one a late 5th-century monophysite priest who settled at Antioch and the other a monophysite at the time of Bishop Paul (512) but who became orthodox under Bishop Asclepius (522). Jacob of Edessa distinguishes the three Isaacs; Gennadius knows of two. According to Zacharias Rhetor, Isaac visited Rome, and Dionysius Telmaharensis mentions his poems on the secular games of 404 and the capture of Rome (410) by Alaric. The Jacobite patriarch bar Shushan (d. 1073) calls him the disciple of Ephraem's pupil Zenobius. If Isaac is the author of the poem on the destruction of Antioch by earthquake in 459, the date of his death must be later than this, but some, *e.g.*, Duval, ascribe the poem to the earlier Edessene Isaac. Bar Shushan collected Isaac's writings but included many which have to be allotted to his namesakes and some even to Isaac of Nineveh, while some ascribed to Ephraem may be Isaac's, so great is the copyists' confusion, which modern scholars have not yet fully resolved.

(W. D. MCH.)

ISAACS, JORGE (1837–1895), Colombian poet and novelist, whose best work, *María*, is the most famous Latin-American novel. Isaacs was born at Cali, in the province of Cauca, Colombia, in April 1837, the son of a prosperous English Jew. He received an excellent education, first at Bogotá and later in England. During the War of the Cauca (1860–63) he was reduced to poverty by the destruction of his patrimony in the Cauca valley. Settling in Bogotá in 1864, he published a slight volume of *Poesías*, which attracted considerable attention, and in 1867 the novel *María*, which won immediate recognition and remains his chief title to fame. Seizing the opportunity thus opened to him for a political career, he entered public life, and in 1871–72 was appointed consul general in Chile. On his return he served in the provincial legislatures of Cauca, Cundinamarca and Antioquia, and filled numerous political, educational and editorial positions. He died in Ihagué on April 17, 1895.

Although Isaacs continued to write until his death and was a generous contributor to periodical literature, none of his later efforts fulfilled the promise of his first two volumes. An idyllic picture, very likely autobiographical, of life among the Cordilleras of his native Cauca valley, *María* was called by one eminent critic "the poem of America" and was translated into several foreign languages. Among his notable poems are "Río Moro," "En la Noche Callada" ("In the Silent Night") and "La Tumba del Soldado" ("The Soldier's Tomb"); *Saulo* is part of an uncompleted drama; *La Revolución radical en Antioquía* is his most important prose work outside fiction.

ISAAK, HEINRICH (*c.* 1450–1517), the leading Flemish composer of his generation, was probably born in Brabant. He may have been in Italy *c.* 1474–82, initially as a pupil of the famous Florentine organist Antonio Squarcialupi. He was certainly at the imperial court in Innsbruck in 1484. He then moved to Florence, where he taught in the household of Lorenzo de' Medici and set to music some of Lorenzo's own carnival songs. He apparently left Florence during the Medicean exile, returning to imperial service in 1494–95; he was officially appointed court composer in 1497, though he spent most of his life elsewhere. Between 1497 and 1514 he traveled extensively, finally settling in Florence, where he died in 1517.

Isaak's main publications were a collection of Masses (Venice, 1506) and the posthumous *Choralis Constantinus* (Nürnberg, 1550–55). The latter is the first complete polyphonic setting of the Proper of the Mass for all Sundays (and certain other feasts); it also contains five settings of the Ordinary. At least part of the work was commissioned for the diocese of Constance in 1508 and employs plainsongs unique to the Constance liturgy. Isaak left his great monument unfinished: the task of completing it fell to his pupil, the Swiss composer Ludwig Senfl.

In his sacred music, Isaak treats *cantus firmus* with infinite resourcefulness, placing the chant in any voice or sharing it between two parts, either in long notes or embroidered with shorter values; he also uses it as the thematic basis of contrapuntal imitations—a technique that came to dominate 16th-century music. Like Jakob Obrecht, he delighted in sequences and, like Josquin Després, in hovering, self-extending rhythms. In many respects, cosmopolitan and eclectic, Isaak remains Flemish in his rather hollow harmonies and his love of mensural intricacies. His Italian *frottole* have charming treble melodies, simply accompanied. His German *Lieder* normally present the tune in the tenor but avoid the sectional cadences of his contemporaries. Exceptionally, his famous "Innsbruck, ich muss dich lassen" recalls the style of the *frottola*. This song was later reworked as a chorale, "O Welt, ich muss dich lassen," familiar today through the arrangements by J. S. Bach and Johannes Brahms.

Isaak's secular music, edited by J. Wolf, appeared in *Denkmäler der Tonkunst in Oesterreich*, vol. 14, no. 1 (1907). His *Choralis Constantinus*, edited by E. Bezecny *et al.*, was published in the same collection in four volumes between 1898 and 1909; a final volume, edited by L. Cuyler, appeared in the U.S. in 1950. *Missa Carminum* was edited by R. Heyden (1930).

See H. Osthoff, *Die Niederländer und das deutsche Lied* (1938).
(B. L. TR.)

ISABELA, Philippine province in northeastern Luzon (*q.v.*). Area 4,069 sq.mi.; pop. (1960) 442,062. The eastern section comprises the rugged, sparsely populated Sierra Madre, which extends to the Philippine sea. Central and western Isabela lie in the fertile Cagayan valley, an important pioneer area since the early 1930s. Rice is the main crop, with surpluses shipped to Manila; corn is the leading local food crop. The production of Virginia tobacco is significant. The provincial capital and agricultural centre is Ilagan. (R. E. HE.)

ISABELLA (ELIZABETTA FARNESE; Spanish ISABEL DE FARNESIO) (1692–1766), queen consort of Philip V of Spain, was born in Parma on Oct. 25, 1692, the daughter of Odoardo Farnese (d. 1693), the eldest son of Ranuccio II of Parma and Piacenza. She was chosen as Philip V's second wife by the princesse des Ursins (*q.v.*), at the suggestion of the then Parmesan representative at Madrid, Giulio Alberoni (*q.v.*), and the marriage took place by proxy at Parma on Sept. 16, 1714. When, shortly after her arrival in Spain, Isabella was met by the princesse des Ursins at Jadraque, near Guadalajara, on Dec. 23, 1714, the queen, acting on the advice of Alberoni, forthwith dismissed the princess from her post of *camarera mayor* and sent her into exile. United with Philip the following day, Isabella immediately established over him a complete ascendancy, which she continued to exercise until his death 32 years later.

The direction which Isabella gave to Spanish policy was governed by the fact that Philip V had two sons surviving from his first marriage. Isabella's children—she bore Philip four sons and three daughters—therefore appeared to have little prospect of succeeding to the Spanish throne, and their mother sought instead to secure for them the Farnese lands in Italy. This quest dominated European diplomacy for more than 30 years; in it Isabella achieved remarkable success, her eldest son Charles (afterward Charles III of Spain) becoming successively ruler of Parma and Piacenza (1732) and of Naples (1734), while his brother Philip was recognized as duke of Parma in 1748. During the reign of her stepson, Ferdinand VI (1746–59), Isabella was removed from court, and although she was allowed to return for a short time after the accession of Charles III in 1759, she never exercised any real influence after the death of Philip V. She died at Aranjuez on July 11, 1766.

Isabella may justly be criticized for diverting Spain's meagre resources to narrow personal and dynastic ends, but the energy with which she pursued her aims, together with her capacity for choosing able and devoted ministers, gave a fresh vigour to the direction of Spain's internal affairs and were largely responsible for the improvement in the country's economy which occurred during the reign of Philip V. *See* also SPAIN: *History*.

See E. Armstrong, *Elisabeth Farnese* (1892); J. O. Lindsay (ed.), *The New Cambridge Modern History*, vol. vii (1957). (B. J. R.)

ISABELLA I THE CATHOLIC (Sp. ISABEL LA CATÓLICA) (1451–1504), queen of Castile from 1474 to 1504, was born at Madrigal on April 22, 1451, the daughter of John II of Castile by his second wife, Isabella of Portugal. Her marriage (1469) to the future Ferdinand II (*q.v.*) of Aragon led to the unification of Spain, and during her reign she restored the authority of the crown after its extreme weakness under her immediate predecessors. Ferdinand and Isabella succeeded as joint sovereigns to the throne of Castile on the death (Dec. 1474) of Isabella's half brother Henry IV, who had been forced to acknowledge her as his heir in preference to his own daughter Joan (*see* HENRY, kings of Castile). Afonso V of Portugal took up the claims of Joan but Isabella's Castilian army defeated the Portuguese at Toro (1476). In 1479 Ferdinand succeeded to the throne of Aragon and two years later associated Isabella with himself in the government of that kingdom. From 1481 the "Catholic Kings," as Ferdinand and Isabella were then known, ruled both kingdoms jointly, but it was a union of crowns and not of countries. The two kingdoms maintained their separate laws, institutions and governments (*see* SPAIN: *History*).

The Catholic Kings' first task was to fight the lawlessness in Castile. To this end they reorganized the medieval *hermandad* (*q.v.*). Isabella acquired a reputation for great severity but also for justice. The traditional policy of later Spanish monarchs in providing equal justice for all classes was undoubtedly due to her, but both in her own time and later this policy was only partly successful. Ferdinand and Isabella relied on the support of the towns in the Cortes to break the power of the nobles, who were forced to give up the crown domains which they had acquired. In her will, Isabella retracted her own grants of crown lands, an action which was regarded as sharp practice but justified by political necessity. Isabella induced the orders of Santiago, Calatrava and Alcántara to accept Ferdinand as their grand master, thus giving the crown the control over their vast property and patronage. The Cortes, once it served its purpose as an ally against the nobility, was summoned only very infrequently. The towns were brought under royal control by the appointment of corregidores (royal officials) to their administration. The royal councils were reorganized, the grandees being virtually excluded and their place taken by professional administrators and lawyers.

To win control over the Spanish church, Ferdinand and Isabella obtained from the pope the right to appoint all high ecclesiastical dignitaries. In 1478 they further obtained a papal bull establishing the Spanish Inquisition as a royal council under royal control. After a prolonged propaganda campaign, the Inquisition persuaded the Catholic Kings to expel the Jews (1492). With her narrow view of religion and influenced, no doubt, by the ecclesiastics in her entourage, Isabella was firmly convinced that she was fulfilling a pious duty in saving her subjects from contact with the heterodox. Most of her contemporaries agreed with her though it is doubtful whether the cynical Ferdinand was motivated by anything but political considerations. The expulsion of the Jews was not only extremely cruel but also economically disastrous for Spain. At the moment when Spain needed all its economic resources to sustain its new European position and overseas empire, Isabella deprived the country of its economically most active citizens and laid it open to exploitation by German and Italian financiers. Isabella was the moving spirit in the conquest of Granada and she fully supported Cardinal Jiménez de Cisneros in his policy of forced conversion of the Moors. The Moors rebelled (1502) and were defeated. Those who refused to be converted were expelled, just as the Jews had been.

Isabella died at Medina del Campo on Nov. 26, 1504. The Catholic Kings had given the monarchy in Castile a completely new basis of power and laid the foundations of Spain's political greatness in the 16th century. It was typical of Isabella's political vision that she agreed to finance the expedition of Christopher Columbus (*q.v.*). Isabella's religious policy, however, while typical of its age and even more of the succeeding age, has found full approval only from those historians who thought that no price was too high to pay for religious unity.

Isabella had five children: Isabel (1470–98), who married Manuel I of Portugal; John (1478–97), prince of Asturias; Joan (*q.v.*), "the Mad"; Maria (1482–1517), who also married Manuel I; and Catherine (*q.v.*) of Aragon.

ISABELLA II (1830–1904), queen of Spain from 1833 to 1868, was born in Madrid on Oct. 10, 1830, the elder daughter of Ferdinand VII by his fourth wife María Cristina. Isabella's right to succeed to the throne was disputed by supporters of her uncle, Don Carlos, and her accession (Sept. 1833) precipitated a lengthy civil war (1833–39). During the queen's minority (1833–43) her mother and Gen. Baldomero Espartero acted as successive regents. In 1843 a military revolt drove Espartero from power and Isabella was declared of age. The period of Isabella's personal rule was, like the regency, a time of political instability: between 1833 and 1868 there were about 60 different governments in Spain and four separate constitutions were formulated amid a constant succession of risings and *pronunciamientos* (*see* SPAIN: *History*). For this state of affairs, Isabella's capricious nature and her attempts to rule despotically in the face of growing demands for a more progressive regime were largely to blame.

The queen married on Oct. 10, 1846 her cousin Francisco de Asís de Borbón (1822–1902), duque de Cádiz. He was widely believed to be impotent, and the simultaneous marriage of Isabella's younger sister to Louis Philippe's son, the duc de Montpensier, provoked a grave crisis in Anglo-French relations. The king consort was not of Isabella's own choice nor to her liking and she in fact lived mainly in separation from him. Scandalous reports of her conduct were circulated and this damage to the reputation of the monarchy, together with other discontents, led to Isabella's deposition on Sept. 26, 1868.

Shortly afterward Isabella went into exile, taking up residence in Paris. There, in 1870, she abdicated her rights in favour of her eldest surviving son, the future Alfonso XII (*q.v.*). She died in Paris on April 9, 1904. Apart from Alfonso, Isabella had eight other children, but of these only three survived infancy.

See also SPAIN: *History*. (R. S. Ll.)

ISABELLA OF BAVARIA (in French called ISABEAU DE BAVIÈRE) (1371–1435), queen consort of Charles VI of France, was the daughter of Stephen III, duke of Bavaria, and was married on July 17, 1385. Her husband's sudden insanity (Aug. 1392) caused her profound distress; she long pursued every imaginable remedy for him, both medical and supernatural. She bore the king six children between 1393 and 1403; but as his derangement grew

worse his rebuffs gradually drove her into flagrant misconduct, which was publicly censured by a court preacher as early as 1405. Her brother-in-law, Louis, duc d'Orléans (*q.v.*) became her constant companion, but this may be explained by the necessities of government, and it cannot be proved that he was her lover.

Isabella was frequently regent for her husband. After the murder of Orléans (1407) she relied for support on John (*q.v.*) the Fearless, duke of Burgundy, who rescued her from a brief imprisonment (1417) and with her set up a shadow government at Chartres and then at Troyes. Her gravest political act was the signing of the treaty of Troyes (1420), which disinherited her son Charles (afterward Charles VII) in favour of Henry V of England. She survived her husband 13 years, repudiated by her son, abandoned by the duke of Burgundy, despised by the English and loathed by the French. She died in Sept. 1435 at the Hôtel St. Pol in Paris. Capricious rather than able, Isabella had misjudged the French situation and rashly played a political game utterly beyond her skill.

BIBLIOGRAPHY.—A. Vallet de Viriville, *Isabeau de Bavière* (1859); M. Thibault, *Isabeau de Bavière—la jeunesse* (1903); J. d'Avout, *La Querelle des Armagnacs et de Bourguignons* (1943) (J. D'A.)

ISABELLA OF FRANCE (*c.* 1296–1358), queen consort of Edward II of England, played a principal part in the deposition of the king in 1327 (*see* EDWARD II). The daughter of Philip IV of France, Isabella was betrothed to Edward by the treaty of Montreuil (1299). The marriage took place on Jan. 25, 1308, at Boulogne, when Isabella was about 12 years old. Despite the suggestions of certain chroniclers, there is no evidence of any early quarrel between Isabella and Edward. By her marriage Isabella had two sons, Edward (afterward Edward III) and John of Eltham, earl of Cornwall, and two daughters, Eleanor of Woodstock and Joanna, later the wife of David II of Scotland. Isabella had extensive possessions in both France and England. After her marriage she was given the counties of Ponthieu and Montreuil for her personal expenses. After the death of Margaret, the queen mother, in 1318, other lands and revenues were made available to her. Altogether Isabella held manors and castles in north Wales and 17 English counties.

Isabella's early interventions in politics were conciliatory. After the murder of the king's friend, Piers Gaveston, in 1312 she attempted to promote peace; she was entrusted with a mission to France (1314) and was active in arranging the settlement of Leake in 1318. In the 1320s, however, Edward's new favourites, the Despensers, aroused Isabella's antagonism. On the pretext of a French invasion her estates were seized in 1324. Isabella sailed for France in 1325 in an attempt to settle the question of Gascony and was joined there by her son, Edward, prince of Wales. From France she made public her refusal to return to England until the Despensers had been removed from court. Joined by Roger Mortimer of Wigmore (*see* MORTIMER), whose mistress she became, and other baronial exiles, Isabella crossed to Essex in Sept. 1326 and routed the forces of Edward and the Despensers.

After the accession of Edward III in 1327, Isabella and Mortimer (created earl of March in 1328) enjoyed a brief period of influence. Her dower was restored and other grants were made to her. In 1330 Edward III's assertion of independence and the arrest and execution of Mortimer marked the end of her power. She was sent into retirement but her movements were not restricted. Her wealth was considerable, but in her old age Isabella took the habit of the Poor Clares and after her death in 1358 was buried in the Franciscan church at Newgate. (J. TA.)

ISABELLA OF HAINAUT (1170–1190), queen-consort of France from 1180 to 1190, was the daughter of Baldwin V, count of Hainaut, and Margaret, sister of Philip of Alsace, and was born in 1170 at Lille. She was married in 1180 to Philip II Augustus and brought to him as her dowry the province of Artois. This marriage brought about the revolt of the house of Champagne; hence Isabella's coronation could not take place at Reims, and she was crowned at St. Denis instead on May 29, 1180.

In 1184 Philip, waging war against Flanders, was angered at seeing Baldwin support his enemies and called a council at Senlis for the purpose of repudiating his wife. But Isabella succeeded in dissuading him from this purpose. She died in 1190. Her son became Louis VIII of France.

ISABEY, JEAN BAPTISTE (1767–1855), French painter of miniatures, was born at Nancy on April 11, 1767. He went to Paris in 1785 and later became a pupil of J. L. David. Employed at Versailles on portraits of the dukes of Angoulême and Berry, he was given a commission by Marie Antoinette, the first of many which he received up to his death (in Paris, April 18, 1855) from the successive rulers of France. Patronized by Josephine and Napoleon, he arranged the ceremonies of their coronation and prepared drawings for the publication intended as its official commemoration, a work for which he was paid by Louis XVIII, whose portrait he executed in 1814. Although Isabey did homage to Napoleon on his return from Elba, he continued to enjoy the favour of the Restoration, and took part in arrangements for the coronation of Charles X.

The monarchy of July conferred on him an important post in connection with the royal collections, and Napoleon III granted him a pension and the cross of commander of the Legion of Honour. "Review of Troops by the First Consul" was one of his most important compositions, and "Isabey's Boat," a drawing of himself and family, had an immense success at the Salon of 1820. His portrait of "Napoleon at Malmaison" is held to be the best likeness of the ruler ever executed. His son and pupil Louis Gabriel Eugène Isabey (1804–86) was a genre and marine painter and water colourist.

See Marion W. Osmond, *Jean Baptiste Isabey, the Fortunate Painter* (1947).

ISAEUS (*c.* 420 B.C.–*c.* 350 B.C.), a professional speech writer at Athens specializing in testamentary law, whose lucidity and logical method were a landmark in the development of forensic oratory. Accounts of his life are scanty and contradictory. His father is said to have been called Diagoras, which is not an Athenian name. According to one ancient source Isaeus was a Chalcidian, according to another an Athenian. To account for this discrepancy it has been suggested that his family belonged to a settlement of Athenian citizens at Chalcis. At any rate he spent his professional life in Athens, either as a citizen or as a resident alien. He appears to have taken no part in public life, but this is in itself no evidence that he was an alien: he may merely have had no desire to speak in public.

His profession was to write speeches for clients. He appears to have confined himself entirely to forensic speeches and almost entirely to those concerned with private suits. He had a minute knowledge of the laws of inheritance and expert skill in exploiting this knowledge to win a case. Too much weight should not be attached to ancient reports that he was a pupil of Isocrates and Lysias. Of Isocrates' influence his work shows little trace. The influence of Lysias is indeed unmistakable, but probably, as Dionysius of Halicarnassus says in his work on the Attic orators, Isaeus merely imitated him. Ancient stories of his personal relations with Demosthenes can largely be discounted, but there is no doubt that Demosthenes' writing owed much to him.

The author of the pseudo-Plutarchean life of Isaeus says that 64 speeches were ascribed to him of which he believed 50 to be genuine. Eleven are extant and a considerable part of a 12th has been preserved in Dionysius' essay on Isaeus. In most cases dating can only be tentative, but all belong to the first half of the 4th century B.C. Every one of the 11 speeches deals, directly or indirectly, with a will. Six relate to disputed claims to an inheritance and three to prosecutions for false witness in testamentary suits. The fifth speech concerns an action brought to compel a man to discharge his obligations as surety in connection with a will, and the 11th the indictment of a guardian for ill-treatment of his ward. The incomplete 12th speech is not connected with a will case; it refers to an appeal to a law court by a certain Euphiletus against the decision of his demesmen to strike him off the register. Many fragments and titles of other speeches have also survived.

The professional speech writer was faced with a difficult problem. It was essential to present a case in a convincing and persuasive form, but if the writer's skill were too transparent, the jurors would be on their guard and the client's case might suffer.

It is clear that Antiphon's self-conscious artistry had been found unsuitable for practical oratory. Lysias had allayed suspicions by writing in a simple style and by skillfully adapting the language and manner of a speech to the character of each particular client. Such characterization is not to be found in the work of Isaeus, but he resembles Lysias in the simplicity and clarity of his language and in avoiding pretentious embellishments. He makes sparing use of such linguistic adornments as antithesis, parison and anaphora. On the other hand he indulges freely in the so-called "figures of thought"; *e.g.*, rhetorical questions and the imaginary objections of an opponent.

Scholars have pointed out some divergences from strict Attic idiom in his writing; it is possible that these may be due to manuscript corruption. In general his style is lucid and businesslike, and the very fact that it lacked literary charm probably added to its effectiveness. In the arrangement of this matter Isaeus shows himself remarkably independent of the rules for subdivision prescribed by rhetoricians. He follows no single plan but varies the structure according to the needs of each particular speech. He shows particular skill in interweaving narrative and proof, thereby avoiding a long, unbroken relation of facts, which in testamentary cases might be complicated and difficult to follow.

Perhaps Isaeus' most significant contribution to forensic oratory lay in his method of argument; he appears to have been the first orator to build up his case point by point with logic and reason. At the same time he took pains to make his arguments intelligible, by frequent repetition and recapitulation at the end of a speech.

BIBLIOGRAPHY.—The text of Isaeus' extant speeches was edited by T. Thalheim, "Teubner Series" (1903); with commentary but excluding fragments, by W. Wyse (1904); with translation by P. Roussel, "Budé Series" (1922) and by E. S. Forster, "Loeb Series" (1927). *See* also F. Blass, *Die attische Beredsamkeit*, vol. ii, 2nd ed. (1892); R. C. Jebb, *The Attic Orators From Antiphon to Isaeus*, vol. ii, 2nd ed. (1893). For the technicalities of Attic law *see* J. H. Lipsius, *Das attische Recht und Rechtsverfahren* (1905–15). (H. L. H.-W.)

ISAIAH, ASCENSION OF, a composite Jewish-Christian work dating in its present form from around the 3rd century A.D., which gathers together certain extrabiblical legends associated with the name of Isaiah.

The first five chapters tell the story of the Martyrdom of Isaiah, in which Isaiah resolutely accepts a painful death rather than recant his faith. The purpose of the story, which dates from the 1st or more probably 2nd century B.C., is obviously to encourage Jews to stand firm under persecution, and it was probably this which commended it to Christian editors in their time of persecution later.

Embedded in this story is a section (iii, 13–iv, 18) that is generally recognized as a separate Christian document, known as the "Testimony of Hezekiah," in which, on his deathbed, the king foresees the coming of Christ. In ch. vi–xi it is told how Isaiah was taken on a journey through the seven heavens and was given foreknowledge of the life of Christ. Now known as the "Vision of Isaiah," it was this *ascensio* of the prophet that gave its name to the whole work.

Both the Testimony and the Vision are Christian in origin and probably date from early in the 2nd century. They are intended to support the claim that Old Testament prophets foresaw and foretold the messianic role of Jesus. All three sections probably circulated separately at first and were brought together at a time when the possibility of persecution was still sufficiently real to give relevance to the Martyrdom (*i.e.*, not later than the beginning of the 4th century). The value of the two Christian sections is the light they throw on the growth of doctrine and institutions in the early church (Trinity, incarnation, resurrection, heaven; criticism of increasing worldliness of the clergy; the spread of heresies), though this is mitigated by the lack of firm dating.

The work survives as a whole only in Ethiopic, but Greek, Latin and Slavonic fragments are extant. The literary relationship of these versions is not easy to determine, but no serious challenge has been offered to R. H. Charles's account of the book in his classic edition, *The Ascension of Isaiah* (1900).

See O. Eissfeldt, *Einleitung in das Alte Testament* (1956).
(ST. B. F.)

ISAIAH (ESAIAS, ISAIAS), **BOOK OF,** in the Old Testament, is the first of the three Major Prophets (with Jeremiah and Ezekiel), or longer prophetic books, as contrasted with the Minor Prophets which together make up a scroll of about the same length, "The Book of the Twelve." Isaiah's 66 chapters comprise material from before (i, 1), during (xliv, 28) and after (lvi, 2–8) the Babylonian exile of the Jews (597–537 B.C.). The book has as its nucleus in ch. i–xxxix collections of prophetic oracles by, and narratives concerning, the prophet Isaiah son of Amoz, one of the four 8th-century prophets (with Amos—not identical with Isaiah's father—Hosea and Micah). A second major element in the book is a collection of prophetic poems in ch. xl–lv from an unknown writer who addresses himself to the situation of the Jews toward the end of the Babylonian exile about two centuries after the inception of Isaiah's prophetic ministry. Isaiah is the book most quoted in the New Testament because of its references to the messianic age and to the witness, rejection, suffering, death and exaltation of the chosen Servant of the Lord. It was also a favourite of the Qumran sect (*see* DEAD SEA SCROLLS).

Contents.—The book may be outlined as follows (passages of special interest are noted in parentheses):

i–xxxv	
i–v:	oracles, chiefly of judgment upon Judah and Jerusalem for pride, depravity, social injustice and perversion of religion ("your sins are like scarlet," i, 18; "swords into plowshares," ii, 4)
vi–viii, 18:	narratives and oracles; Isaiah's vision, the three signs to Ahaz, the prophet's temporary retirement ("Holy, holy, holy is the Lord of hosts," vi, 3; "If you will not believe, surely you shall not be established," vii, 9; "a young woman [virgin] shall conceive . . . a son . . . Immanuel," vii, 14)
viii, 19–x, 4:	oracles of doom and promise of the messianic king ("to us a child is born . . . Prince of Peace," ix, 6)
x, 5–xii, 6:	the Assyrian threat and the messianic ruler to come ("Assyria, the rod of my anger," x, 5; "a shoot from the stump of Jesse," xi, 1)
xiii–xxiii:	doom oracles on foreign peoples ("Babylon, the glory of kingdoms . . . will be like Sodom," xiii, 19; "How you are fallen from heaven," xiv, 12; "I will break the Assyrian," xiv, 25; "Isaiah . . . naked and barefoot . . . as a sign," xx, 3)
xxiv–xxvii:	a booklet of eschatological prophecy, psalms and prayers ("He will swallow up death for ever," xxv, 8)
xxviii–xxxii:	oracles chiefly on divine sovereignty over historic events ("a covenant with death," xxviii, 15; "in Zion . . . a precious cornerstone. . . . He who believes will not be in haste," xxviii, 16; "in quietness and in trust shall be your strength," xxx, 15; "The Egyptians are men, and not God," xxxi, 3; "a king will reign in righteousness," xxxii, 1)
xxxiii–xxxv:	a prophetic liturgy; the fearful doom of Edom; the joyful return to Zion ("the desert shall rejoice," xxxv, 1; "sorrow and sighing shall flee away," xxxv, 10)
xxxvi–xxxix:	modified excerpt from II Kings xviii, 13–xx, 19, concerning Isaiah's part in the crisis of Sennacherib's invasion in 701 (or 688?) B.C., and related matters ("Whom have you mocked and reviled? . . . the Holy One of Israel," xxxvii, 23; "I will defend this city," xxxvii, 35)
xl–lv:	prophetic poems of lyrical joy on the imminent deliverance of his people from Babylonian exile by Yahweh, Israel's Redeemer and the only true God. Incorporated within these chapters are four distinctive poems picturing the mission, suffering, justification and triumph of Yahweh's chosen Servant (xlii, 1–4 or –7; xlix, 1–6; l, 4–9; lii, 13–liii, 12; xlviii, 16c may be a fragment of another Servant poem)
xl–xlviii:	proclamation to the exiles of deliverance, at hand through the agency of Cyrus, in fulfillment of Yahweh's eternal purpose and as a demonstration to the world that he alone is God; the futility of idolatry and the downfall of the Babylonian gods; the mission of the chosen Servant ("Comfort, comfort my people," xl, 1; "In the wilderness prepare the way of the Lord," xl, 3; "He will feed his flock like a shepherd," xl, 11; "Behold my servant, whom I uphold," xlii, 1; "Before me no god was formed, nor shall there be any after me," xliii, 10; "Thus says the Lord to his anointed, to Cyrus, . . . I will go before you," xlv, 1–2; "Bel bows down, Nebo

stoops," xlvi, 1; "Go forth from Babylon," xlviii, 20)

xlix–lv: the consolation and abundant restoration of Zion under the everlasting covenant of Yahweh, her Maker and Redeemer; the chosen Servant's rejection and his wider mission; his persecution and death for others' sins and his promised reward ("I will give you as a light to the nations," xlix, 6; "he who vindicates me is near," l, 8; "Awake, awake, put on your strength, O Zion," lii, 1; "he was wounded for our transgressions," liii, 5; "my word . . . shall accomplish that which I purpose," lv, 11)

lvi–lxvi: admonitions to the restored community; new calls to rejoicing in view of the glorious future promised; a universal judgment and a new creation ("the Lord's hand is not shortened, that it cannot save," lix, 1; "Arise, shine; for your light has come," lx, 1; "the Lord has anointed me to bring good tidings," lxi, 1; "I create new heavens and a new earth; . . . I create Jerusalem a rejoicing," lxv, 17–18; "by fire the Lord will execute judgment," lxvi, 16)

Themes.—The central thought in the prophecies of Isaiah himself in ch. i–xxxix is that of the holy majesty of God, a terrible divine righteousness which confronts and confounds the pretensions of men and overrules the course of events in fulfillment of God's purpose for his people. The "Holy One of Israel" will not tolerate injustice and depravity among his people or their rulers, nor accept worship which is less than a wholehearted response to his ethical holiness. The pride and materialism of Judah's leaders —and, above all, their frantic search for political security through schemes which belie their claims to be Yahweh's people—can bring only disaster. Judah's only hope is to learn the meaning of religion, as ethical loyalty and complete trust in the unseen but conclusive mastery of events by God. A chastised and repentant people will know that Yahweh is both her judge and her defender.

In ch. xl–lxvi the central theme is Yahweh's imminent inauguration of a new age for his people by coming to deliver her from the captivity, suffering and spiritual defeat in which the old age had ended. The act of redemption through Yahweh's chosen instrument, the Persian conqueror Cyrus, will be at the same time a new act of creation in the realm of spirit. It will fulfill his unchanging and undefeated purpose made known in the covenants with Noah, Abraham and David; it will be a new Exodus to the land of promise. Nature itself will be re-created when Israel is reborn. This new mighty act of God is to be an act at once of creation, revelation and redemption, displaying the omnipotence of him who is the first and the last, the universal and only God. In contrast, the gods of the heathen will be shown to be no gods at all, because they are impotent to reveal and accomplish a creative purpose. Israel is summoned to take up the task of witness for which she has been chosen; she is called from fear to faith, and from spiritual defeat to the joyous liberation of spirit which will be a light to the nations.

The Songs of the Suffering Servant strike a muted note amid this paean of rejoicing. Their subject is the meaning of suffering as the means whereby Yahweh will bring salvation to mankind. The Servant who is chosen to mediate God's message to the nations is ignored, despised, persecuted and finally put to death. But, as a result, the kings and people learn that the suffering of the innocent and obedient at the hands of the rebellious effects an atonement which is within the purpose of God. The attempt to identify the Suffering Servant as an individual or collective figure is futile; he is not simply a martyred prophet, a suffering just man like Job, a king who dies for his people in symbolic ritual, or the empirical or the ideal Israel. The Servant is the composite portrait of an *idea* that defies precise identification and transcends any temporal setting. He personifies the redemptive and creative power of innocent suffering willingly accepted as the cost of bearing witness to the will of God. It is not surprising that this portrait provided the writers of the New Testament with the principal clue to the meaning of the crucifixion of Jesus Christ, though attention to the details of the portrait shows that the correspondence is on a deeper level than mere prediction.

Literary History.—The process through which the Book of Isaiah reached its present form represents a complex problem to which there is no agreed solution except in broad outline. The obvious differences between adjacent passages and different parts of the book—in literary forms and style, religious ideas, historical background and condition of those addressed—together with the sharp breaks in continuity, show that it was put together by many hands over a long period of time. Its oldest materials are the oracles of Isaiah's early period, shortly after his call to prophesy in 742 B.C. It was complete and believed to be throughout a prophecy of Isaiah by the time of Sirach (*cf.* Ecclus. xlviii, 17–25), *c.* 190 B.C., and probably considerably earlier than that. Ezra i, 1 (*c.* 400 B.C.), however, seems to attribute Isa. xlv, 1–7 to Jeremiah, in whose book there is no mention of Cyrus; this suggests that ch. xl–lxvi had not yet been attached to ch. i–xxxix. That a relevant section of II Kings (xxiv, 18–xxv, 21, 27–30) is appended to the Book of Jeremiah strongly suggests further that Isa. xxxvi–xxxix is a similar appendix to an earlier form of the Book of Isaiah, before the addition of ch. xl–lxvi and the insertion of the related ch. xxxiv–xxxv. The complete scroll of Isaiah found at Qumran in 1947 exhibits a unique space between ch. i–xxxiii and xxxiv–lxvi, which may indicate that in one form of the manuscript tradition the two parts of the book were recognized as distinct.

Although the unity of the book is still defended by some on dogmatic grounds, it cannot be maintained in the face of the internal evidence. The decisive point is that, whereas the superscription in i, 1 designates what follows as "the vision of Isaiah" in the reigns of four kings of Judah of the Assyrian period in the latter part of the 8th century B.C. while the Temple was unharmed, the second part of the book is addressed to Jews who are captives of the Babylonian power which succeeded the Assyrian, or who look back to the exile of 597–537 B.C. The overthrow of Babylon by Cyrus, the Persian king, is imminent (xlv, 1–7) and "the captive daughter of Zion" (lii, 2) is to be set free. The Temple has been destroyed by fire (lxiv, 11). It is in this situation that the poet utters his message of comfort and hope: Jerusalem's warfare is ended (xl, 2); for Israel's sake God her Redeemer will "send to Babylon and break down all the bars" (xliii, 14); he says of Cyrus "He is my shepherd," of Jerusalem "She shall be built," of the Temple "Your foundation shall be laid" (xliv, 28).

Ch. xl–lxvi (II Isaiah).—That ch. xl ff. (designated, for convenience, II Isaiah; ch. i–xxxix are referred to as I Isaiah) originated not earlier than the Babylonian exile was hinted by Ibn Ezra in the 12th century and was argued on grounds of internal evidence by J. C. Döderlein (1775) and J. G. Eichhorn (1783). It has long been a commonplace of scholarship, but the further question as to the unity of authorship of the whole of ch. xl–lxvi remains in dispute. The thesis of B. Duhm (1892) that ch. lvi–lxvi are a work of the 5th century B.C. to be distinguished from Deutero-Isaiah, and that within ch. xl–lv four "Songs of Yahweh's Servant" are to be distinguished from the contexts into which they have been inserted, has markedly influenced all subsequent discussion. The majority of scholars from K. Budde (1906) to O. Eissfeldt (1956) and J. Muilenburg (1956) recognize in ch. lvi–lxvi the work not of a single author but of a school of tradition dependent on Deutero-Isaiah. E. König (1926), C. C. Torrey (1928) and L. Glahn (1934) revived the view that ch. xl–lxvi (to which Torrey adds ch. xxxiv–xxxv) are substantially one work, which Torrey however dates about 400 B.C. Several scholars distinguish ch. xl–xlviii and xlix–lv as written by the same author before and after Cyrus' edict of liberation in 538 B.C., and W. Caspari (1934) sees the whole of ch. xl–lv as the work not of an individual but of a group of returning exiles.

Most scholars have followed Duhm in distinguishing within ch. xl–lv the "Songs of Yahweh's Servant," although not always delimiting them as he did (xlii, 1–4; xlix, 1–6; l, 4–9; lii, 13–liii, 12), or agreeing whether they are from a writer earlier than, later than or identical with the author who composed their immediate literary context. In the context the "Servant" is identified as the collective Israel (xli, 8; xliii, 10), suffering deserved punishment but promised restoration in fulfillment of Yahweh's purpose and in order that she should be the witness to the world of his sole deity. In the songs the Servant, though in some sense identified with Israel in xlix, 3, has a mission both to Israel and to the world (xlix, 6). But the portrait is that of an individual, whether it be a

historic, representative, symbolic or mythological figure. He is chosen and endowed by Yahweh with his spirit in order to proclaim Yahweh's truth to the ends of the earth; he is persecuted, suffers and dies for the sins of others in obedience to Yahweh's will; finally Yahweh promises his vindication and triumph (liii, 4–12).

The contrast is most marked in the explanations of the Servant's suffering—in the one case as retributive, in the other as vicarious. Nevertheless the songs have so much in common with their context in thought and phraseology that some scholars, stressing the Hebrew propensity to personify collective groups and abstract ideas (*e.g.*, Amos v, 2; Ezek. xvi, 3; Ps. lxxxv, 10; Heb. lxxv, 11), explain the differences as due to fluidity or development in the thought of Deutero-Isaiah; some reaffim the earlier view that the songs are structurally related to their immediate contexts.

Ch. i–xxxix (I Isaiah).—The literary history of ch. i–xxxix also presents a complicated problem, even though the critic has more concrete data to work with and hence is less dependent on subjective judgment than he is in the analysis of ch. xl–lxvi. The divisions between different sections are more clear-cut. Some sections bear editorial headings which define the time and circumstances of what follows (i, 1; ii, 1; vi, 1; xiii, 1; xiv, 28; xx, 1). In two instances a regular strophic structure with identical refrains shows that passages now separated belong together (ii, 6–22 with v, 14–16; v, 25–30 with ix, 8–x, 4). Autobiographical memoirs (vi, 1–13; viii, 1–18) and historical narratives (vii, 1–17; xxxvi, 1–xxxix, 8) incorporate some oracles and set the prophet Isaiah firmly in the historical scene.

The affinities of ch. xxxiv–xxxv are clearly with II Isaiah rather than with I Isaiah; their present position separating ch. i–xxxiii from its appended historical section ch. xxxvi–xxxix must date from the time when I Isaiah and II Isaiah were combined in a single scroll. The remainder of I Isaiah falls into four divisions which can be distinguished by their subject matter: (1) ch. i–xii, mainly oracles of denunciation and threat from Isaiah's early period; (2) ch. xiii–xxiii, mainly oracles of doom on foreign peoples; (3) ch. xxiv–xxvii, a distinct body of eschatological prophecy, psalms and prayers; and (4) ch. xxviii–xxxiii, mainly oracles from Isaiah's later period, proclaiming trust in Yahweh's purpose as Judah's sole security. Each of these except the third contains material from, or directly related to, the Isaiah who has given the book its name, together with supplementary additions and insertions from a later time.

Views vary as to the process through which these sections, each containing post-Isaianic matter, came into existence and were arranged as they are now found. Duhm (1892) holds that the first two of the present divisions represent small "Books of Isaiah" with independent histories, to which late in the Greek period other miscellaneous matter, ch. xxiv–xxxv, was added. R. H. Pfeiffer (1941) believes that ch. ii–xii were put together from recorded words of Isaiah and supplementary matter soon after the prophet's death, and to this ch. i was later prefaced; ch. xiii–xxvii was a collection of doom oracles on foreign peoples which happened to include some from Isaiah, and xxviii–xxxiii represented a further collection which grew independently around an Isaianic nucleus. O. Procksch (1930) believes that the original oracles in ch. i–vi, ix, 7–x, 4, and xxviii–xxxi were assembled by Isaiah himself, and that a second and a third collection, containing materials relating respectively to the Syro-Ephraimite crisis and to foreign peoples, were made by his disciples. S. Mowinckel (1933) sees in the present book a rearrangement of an earlier one of which the core was vi, 1–viii, 23a, recorded by Isaiah, to which after his death two collections containing genuine oracles were added by his followers, together with further groups of non-Isaianic matter. R. B. Y. Scott (1956) holds that Isaiah himself recorded two groups of his oracles, one from his early period (*cf.* viii, 16–18) and one from his closing years (*cf.* xxx, 8), and that these were the nuclei of two collections which developed independently until they were combined during or after the exile, and then expanded by addition of ch. xxiv–xxvii and a series of eschatological promises.

Prophetic Ministry of Isaiah.—Isaiah (Heb. "may Yahweh save *or* regard [him]") was called to prophesy in the year of King Uzziah's death, *c.* 742 B.C., and was still active at the time of Sennacherib's invasion of Judah in 701 B.C. (or *c.* 688 B.C.; there seem to have been two such invasions). The legend of his martyrdom under King Manasseh (*c.* 692–638 B.C.), which appears in rabbinic tradition and in the apocryphal Ascension of Isaiah (*see* Isaiah, Ascension of) and probably is referred to in Heb. xi, 37, has no known historical basis beyond the general statement of II Kings xxi, 10–16. Internal evidence in I Isaiah indicates that the prophet was a Jerusalemite of the upper classes, married, and with at least two sons. It is possible that before his call to prophesy he was a member of the king's council or a cult prophet, since he had ready access to the king and to the head priest (vii, 3; viii, 2), and his place during a temple ceremony was among those officiating (vi, 4; *cf.* Joel ii, 17). He shows familiarity with the way of life of the ruling group and concerns himself increasingly with matters of public policy (v, 8–23; xxx, 1–2). He champions the poor because of his conviction of the holiness of justice (iii, 14–15; v, 16), rather than by identifying himself with their sorrows as Micah and Amos did.

Isaiah's prophetic voice was raised first in the reign of Jotham (*c.* 742–735 B.C.) in proclamations of impending doom; some of these are coloured by memories of a recent disastrous earthquake (v, 25; *cf.* Zech. xiv, 5), others by forebodings of invasion by Assyrian armies (v, 26–29; vi, 11–12). In 743 the new strong man on the Assyrian throne, Tiglath-pileser III, had begun a series of campaigns into Syria and north Palestine; Menahem, king of Israel, was put under tribute in 738 (II Kings xv, 19). The prophet condemned the social and religious corruption of Judah and Jerusalem, especially the depravity and rapacity of the upper classes, as sins for which Yahweh's hand was outstretched to strike (v, 8–25). From first to last he opposed military adventures in alliance with foreign nations, declaring on one such occasion in Jotham's reign that "only a remnant . . . will return" (x, 22–23) and giving this as a name to his son (Shear-jashub; vii, 3). Thirty years later he was denouncing the rulers who looked for safety in alliance with Egypt (xxx, 1–7; xxxi, 1–3).

Judah's only security lay in confidence in her God (vii, 9; xxviii, 16; xxx, 15). When Damascus and northern Israel invaded Judah to force her into an anti-Assyrian alliance Isaiah offered to the doubting king a "sign," the confident prediction that a child soon to be born would be named Immanuel ("God is with us") in thanksgiving for deliverance. When the panic-stricken Ahaz instead sought safety by imploring Assyrian aid, at the cost of an enormous tribute and the erection in the Temple of an altar to an Assyrian god (II Kings xvi, 7–16), Isaiah retired and recorded his predictions while awaiting their fulfillment (viii, 16–18). Not until after Ahaz' death (*c.* 715) many years later, it seems, did Isaiah resume his public role (xiv, 28). The famous dynastic oracles in ix, 2–7 (Heb. ix, 1–6) and xi, 1–9, which later were applied to the Messiah, may have been composed for the accession ceremonies of Hezekiah, Ahaz' successor.

The oracles of this later period, culminating in those proclaiming that Yahweh would defend Jerusalem against Sennacherib (x, 5–16; xxxvii, 22–29), concentrate on the sovereign purpose of God as determining the course of history and the fate of nations. Assyria is but his instrument (x, 5, 15). Jerusalem will survive, not through Egypt's help (xxxi, 1–3) but by Yahweh's mercy (i, 9) and in order that his sovereignty in the affairs of men and nations might be displayed (xxxvii, 29). What originally had been a threat, Shear-jashub, "*Only* a remnant shall survive" (vii, 3; x, 22–23), is turned into a promise, "A remnant *shall* survive" (x, 20–21; xxxvii, 31–32). A chastised people will have learned that faith in God is the only sure foundation of national security (xxviii, 16; xxx, 15).

Isaiah as Prophetic Literature.—The literary records of Hebrew prophecy in Isaiah make clear that prophecy means in the first instance and primarily a word or spoken message, proclaiming through a chosen messenger the will of God for those addressed. The predictive element of threat or promise is conditioned by the hearers' response (i, 18–20), or is offered as a "sign" of what is coming (vii, 14), because all that happens is finally subordinate to the purpose of God's will. II Isaiah makes much of the im-

potence of Babylon's gods, in contrast to Yahweh, to declare in advance what they intend to do and to do it (xli, 21–24; xlviii, 3). The predictions of the prophets are the announcement of the purpose of a living God rather than of man's predetermined fate.

Oracles.—The public pronouncement of Yahweh's "word" on a particular occasion is an "oracle." Most of the records of prophecy consist of collections of these oracles, as in Isa. i–v and xiii–xxiii. Each oracle usually has a single theme and a clearly marked beginning and end (*e.g.*, i, 10–20) and is in the form of a denunciation culminating in or implying a threat (*e.g.*, xxx, 9–14) or of exhortation and promise (xliii, 1–7). It is too brief to be a sermon or address, but its rhythmic and finished form shows that it was carefully prepared for delivery in memorable words. The prophet speaks like an ambassador delivering a message on behalf of a king (xxxvi, 4; *cf.* xxxvii, 21). Sometimes, as in the names given by Isaiah to his sons, the germ of an oracle may be seen as it presented itself to the prophet's mind in a striking phrase (vii, 3; *cf.* x, 22–23; viii, 3–4).

There are many variations in the form of the oracle. Sometimes a series of them make up a longer oracle with refrains, as in ix, 8, Heb. ix, 7–x, 4 and v, 24–25. Sometimes the prophet casts his "word" in the form of a vintage song (v, 1–7) or the instruction of a sage (xxviii, 23–29). Certain oracles are preserved only in prose form (*e.g.*, x, 20–27). In II Isaiah the oracles become so long and elaborate in structure that most scholars hold that they were written and meant to be read aloud rather than spoken, while still retaining the quality of rhetoric (*cf.* xl, 12–31).

Narrative.—In addition to oracles the Book of Isaiah preserves narrative records. These are of two kinds: (1) memoirs, in which the prophet speaks in the first person of his experiences; and (2) historical narratives or tales describing in the third person what he said and did. In ch. vi, one of the most striking and important passages in prophetic literature, Isaiah tells his own story of the experience in the year of King Uzziah's death, which was his call to be a prophet. Here, as in the further memoir material in viii, 1–8, 11–15, Isaiah distinguishes between what the divine voice said to him and what it commissioned him to proclaim. In vii, 1–17 there is what appears to be a selection from a prophetic biography, again incorporating oracles, as in the selection from II Kings in ch. xxxvi–xxxix which itself drew upon biographical accounts of Isaiah's ministry.

Other Materials.—In the long process through which the Book of Isaiah reached its present form still other materials, unrelated to either of its two principal authors, were added. Ch. xii consists of two short psalms; a psalm ascribed to Hezekiah, not found in II Kings from which its context is taken, appears in xxxviii, 9–20. In ch. xxxiii prophetic oracles alternate with prayers of entreaty and lamentation, in a kind of liturgical dialogue such as is envisaged in Jer. xxxvi, 6–7 and Joel ii, 15–17. In ch. lix a solemn admonition, verses 1–8, is responded to by a congregational confession in verses 9–15. In lxiii, 7–19 and lxiv, 1–12 appear two psalms of lament and entreaty which resemble the prayers for a fast day in the Temple preserved in Ps. lxxiv and lxxix. *See* also BIBLE.

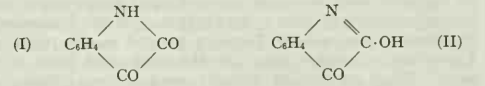
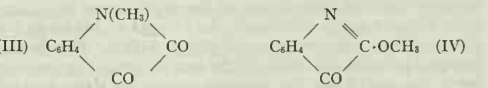
ISALLOBAR, a line entered on a meteorological chart connecting points having the same change in pressure in a given period of time preceding the time of observations represented on the chart. By international agreement, three-hour pressure changes or tendencies are transmitted by all stations and ships to the collecting-distributing centres with each observation. Isallobars may be drawn for these values or for those of 12-hour or 24-hour intervals obtained by comparison with pressure observations taken 12 or 24 hours previously. (H. R. B.)

ISAR (identical with *Isère,* in Celtic "the rapid"), a river of Bavaria, Federal Republic of Germany, and a tributary of the Danube, rises in the Tirolese Alps at an altitude of 5,840 ft. It winds in deep, narrow gorges through the Alps, and at Bad Tölz (2,100 ft.) enters the Bavarian plain, which it traverses in a generally northerly and northeasterly direction, and enters the Danube immediately below Deggendorf. It is 183 mi. long with a drainage area of 3,500 sq.mi. Below Munich the stream becomes a deep steep-sided valley 140 to 350 yd. wide and is studded with islands. It is not navigable, except by rafts. On its banks lie the cities of Munich and Landshut, and the ancient episcopal see of Freising. *See* also DANUBE.

ISATIN, in chemistry, an oxygenated derivative of indole (*q.v.*) prepared originally by oxidizing indigo with nitric or chromic acid. It crystallizes in orange-red prisms melting at 200°–201° C. Isatin is of practical importance in the manufacture of vat colours. For example, it yields Ciba red G (thioindigo scarlet G) by condensation with 2-hydroxythionaphthene and subsequent bromination of the condensation product. Isatin is also of outstanding scientific interest because it was one of the first recognized examples of tautomerism (*q.v.*). It is a chemical individual with two personalities. Certain of its reactions suggest the lactam constitution (I) whereas others indicate the lactim configuration (II).



Although isatin itself exists in only one form, it has two methyl ethers: pseudomethylisatin (III) made from dibromomethyloxindole, and methylisatin (IV) prepared by the interaction of methyl iodide and silver isatin.

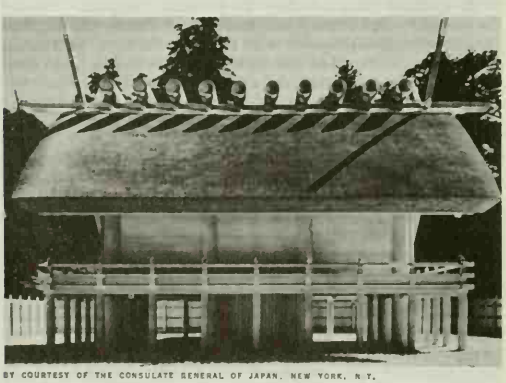


Isatin and its homologues are produced by condensing aniline and its homologues with hydroxylamine sulfate and chloral hydrate; an intermediate isatinimide is formed which on hydrolysis furnishes the corresponding isatin.

ISAURIA, the name in Roman times of a district in Asia Minor equivalent to parts of the *iller* of Konya, Icel and Antalya in modern Turkey. The nucleus of it was that section of the Taurus which lies directly south of Iconium (Konya) and Lystra. Lycaonia had all the Iconian plain; Isauria began at the foothills. When the Romans first encountered the Isaurians (early in the 1st century B.C.), they regarded Cilicia Trachea as part of Isauria, which thus extended to the sea; the whole basin of the Calycadnus (Goksu) river was reckoned Isaurian, and the cities in the valley of its southern branch formed the Isaurian Decapolis. Toward the end of the 3rd century A.D., however, all Cilicia was detached for administrative purposes from the northern slope of Taurus; Pisidia was also detached and made to include Iconium. In compensation Isauria received the eastern part of Pamphylia. Restricted again in the 4th century, Isauria ended as the wild district about Isaura Palaia and the heads of the Calycadnus. During the war of the pirates against Rome (1st century B.C.), the Isaurians took an active part and were reduced to submission. They were afterward placed under the rule of Amyntas, king of Galatia, and their territory was surrounded by a cordon of forts. In the 4th century they are described by Ammianus Marcellinus as the scourge of the neighbouring provinces; but they are said to have been effectually subdued in the reign of Justinian. Isauria passed into the hands of Turkmen and Yuruks with the Seljuk conquest, and is still one of the main haunts of the nomadic tribes of Turkey. The ruins of the capital city, Isaura Palaia, are mainly remarkable for their fine situation and their fortifications and tombs. Those of Isaura Nea have disappeared, but numerous inscriptions and many sculptured *stelae,* built into the houses of Dorla, prove the site. (WM. C. B.)

ISCHIA, an island at the west entrance to the Bay of Naples, in Napoli province, Campania region, Italy, 26 km. (16 mi.) S.W. of Naples and 11 km. (7 mi.) S.W. of the nearest mainland point, Cape Miseno, was known to the Greeks as Pithecusa ("island of monkeys"?) and to the Romans as Aenaria. Oblong in shape, it measures 10 by 7 km. (6 by 4 mi.), with a circumference of 34 km. (21 mi.) and an area of 46 sq.km. (17¾ sq.mi.). The island consists almost entirely of volcanic rock; its highest point, Monte Epomeo (2,585 ft.), is an extinct volcano. The date of its first eruption is estimated to have been about 2200 B.C.; an eruption of the 7th century B.C., according to Pliny, drove away the first Greek settlers, and the eruption of 470 B.C. put the Syracusan garrison to flight. There were several eruptions in Roman times. The last on record occurred in 1302, when all the population fled to Baia on the mainland and did not return for four years. There have been destructive earthquakes more recently, however, the last one in 1883 when the town of Casamicciola was entirely destroyed. The volcanic soils of the island are fertile, and the wine of Ischia, called "Epomeo," is famous. Wheat, olive oil and citrus fruit are the other crops of importance. The potter's clay of Ischia is believed to have been used by the ancient potteries of Cumae and Puteoli (Pozzuoli). The important towns are in the north of the island: Ischia, the administrative centre and seat of a bishop, consisting of the fishing village of Ischia Ponte, with its medieval castle on a tiny peninsula, and Ischia Porto, a spa known for its warm baths (pop. [1957 est.] 11,698 [commune]), on the east; Casamicciola Terme, a spa and seaside resort, and Lacco Ameno, another resort, on the north; and Forio on the west. There are regular shipping services from Naples and Pozzuoli to Ischia and a car ferry from Pozzuoli to Ischia Porto.
(G. Kh.)

ISE (called Uji-Yamada until 1956), a city of Mie prefecture, southern Honshū, contains the most sacred Shintō shrines of Japan. Between 1940 and 1960 the area of the city increased by amalgamation from 61 sq.km. (24 sq.mi.) to 177 sq.km. (68 sq.mi.) and the population increased from 52,600 to 99,026. The Ise-shima National park was established in the area in 1946. The Ise Shrines are in the city of Ise; the two main shrines are about four miles apart and are almost identical in their arrangements. The Outer Shrine is dedicated to Toyouke Ōmikami, goddess of agriculture and silk production. The Inner Shrine is dedicated to Amaterasu Ōmikami, the sun-goddess, traditional progenitor of the Japanese imperial family. The Inner Shrine was established in the late 3rd century, the Outer Shrine in the late 5th century. The former was founded by an imperial princess who was seeking a site for a shrine to house the Sacred Mirror, a part of the imperial regalia and the embodiment of Amaterasu Ōmikami. Until the 14th century the custodian of the shrines was always an unmarried imperial princess. At both shrines the main building is a thatched hut built in ancient Japanese style of unpainted Japanese cypress with only a few touches of gilding at the tips of the roof timbers.



BY COURTESY OF THE CONSULATE GENERAL OF JAPAN, NEW YORK, N.Y.

ISE SHRINE, THE MAIN BUILDING

Since the 7th century it has been the custom to reconstruct these buildings at intervals of about 20 years. Pilgrimages to these shrines are popular among the Japanese people and events of national importance are always communicated to the deities. *See* also Shintō. (A. E. T.)

ISENTROPIC CHART. The isentropic chart is used in weather forecasting and in problems of meteorological research. It was first suggested by Sir Napier Shaw in Great Britain in 1933 and later, in 1936, by Carl-Gustav Rossby in the U.S., when the network of weather stations taking upper air observations (*see* Upper Air Soundings) became sufficient to make construction practical. An isentropic chart shows the moisture distribution and flow of air along a surface of constant entropy, which in meteorology is also a surface of constant potential temperature. (*See* Meteorology.) The isentropic surface is not at a constant level but varies in height from place to place over the earth, the variation being indicated on the isentropic chart by lines (isobars) showing the pressure at which the isentropic surface is found. The moisture distribution is shown by lines of constant mixing ratio expressing the number of grams of moisture per kilogram of air (dry). The flow of air at the isentropic surface is represented by winds recorded from pilot balloon (*q.v.*) observations and stream lines computed from the field of pressure and temperature.

Air particles tend to flow along isentropic surfaces rather than at constant levels. By virtue of this fact the life history of air currents can be conveniently followed from day to day by means of isentropic charts. In addition, they give a lucid picture of the physical processes which produce the weather.

See Jerome Namias, *An Introduction to Air Mass and Isentropic Analysis,* American Meteorological Society (1940). (J. Ns.)

ISEO, LAKE (ancient Lacus Sebinus), a lake in Lombardy, north Italy, lies at the southern foot of the Alps, between the provinces of Bergamo and Brescia. The Oglio enters the northern end at Lovere and leaves the southern end at Sarnico to join the Po. Area 65 sq.km. (25 sq.mi.), length 16 mi., greatest width 3 mi., greatest depth 823 ft., height of surface above sea level 610 ft. On the island of Siviano in Lake Iseo is Monte Isola (1,834 ft.), crowned by a chapel. South of Siviano is the islet of San Paolo, occupied by the buildings of a small disused Franciscan convent, and north is the equally tiny island of Loreto, with a ruined chapel containing frescoes. At the southern end of the lake are the small towns of Iseo, 24 km. (15 mi.) from Brescia, and of Sarnico. Toward the head of the lake the deep, wide valley of the Oglio is seen, dominated by the glittering snows of the Adamello (11,660 ft.). There is a good road along the eastern shore.

ISÈRE, a *département* of southeastern France, formed in 1790 out of the northern part of the old province of Dauphiné (*q.v.*). Area, 3,180 sq.mi.; pop. (1962) 729,789. It extends from the high (Graian) Alps in the Pelvoux massif to the valley of the Rhône, and is bounded across that river by Ain to the north and by Rhône and Loire *départements* to the west. To the southeast and southwest respectively it is bounded by the Alpine *départements* of Savoie and Hautes Alpes, and to the southwest by Drôme lower down the Rhône basin. The Isère river, which receives an important Alpine tributary, the Drac, near Grenoble, crosses the *département* from northeast to southwest.

The *département* comprises diverse physical regions, including parts of the high, snow-capped crystalline mountains of the Belledonne, Grands Rousses and Pelvoux groups, and the Grande Chartreuse and Vercors blocks of the limestone Prealps, with the great longitudinal depression of Grésivaudan between, occupied by the Isère river and, beyond Grenoble, by its tributary the Drac. West of the Prealps is the foreland country of Bas Dauphiné, extending to the Rhône valley within its great bend at Lyons. This district is thickly coated with infertile glacial debris (*terres froides*) and there is much poor woodland and waste, but there are strips of richer farmland along the valleys of the Rhône, Isère and smaller rivers. These favoured tracts and the sheltered extension of the lowland in Grésivaudan are cultivated with cereals, fruit and vines but are especially devoted to meadows and fodder crops. At the foot of the Vercors mountains, near Grenoble, is a specialized area of walnut cultivation. The mountains, receiving

a high precipitation, are heavily forested up to heights of more than 6,000 ft. and timber is an important resource. In the high Alpine valleys, especially the Romanche, a pastoral economy prevails.

A small field of anthracite is worked in the Drac basin at La Mure, but more important is the development of hydroelectric power since the first plan was initiated near Grenoble in 1885. Although most of the power is transmitted from the generating stations in the mountains to the Lyons industrial area, some factories have been attracted to sites in the Alps. The industrial influence of Lyons extends over most of the lowland northwest of the Isère river, with much silk weaving carried on by means of electric power in dispersed workshops and the homes of the rural population. There are also cement works, paper mills, chemical and engineering industries, and the old-established glove manufacture of Grenoble. Persistent emigration from the Alpine valleys has been offset by the increase in industrial employment in the towns and within the textile province of Lyons, so the population of the *départements* is increasing.

Much of the northwestern part naturally looks directly to Lyons as its commercial and industrial capital, but the *préfecture* of the *département* is Grenoble (pop. [1962] 162,764 [commune]), the centre also of ecclesiastical, educational and judicial administration, with a cathedral, university and court of appeal. Situated at the head of the gap by which the Isère cuts through the prealpine range, it is an important route centre. Grenoble, Vienne and La Tour-du-Pin are the centres of the three *arrondissements* into which the *département* is divided. The famous Carthusian monastery of Grande Chartreuse is situated at 3,000 ft. in the mountains north of Grenoble. (Ar. E. S.)

ISÈRE RIVER, a left-bank tributary of the Rhône, in southeast France, 180 mi. long, descends about 8,000 ft. from the high (Graian) Alps on the Italian frontier to its confluence with the Rhône above Valence. It traverses the *départements* of Savoie, Isère and Drôme. Rising as a glacial torrent, its upper course in the high Alpine valley of Tarentaise zigzags across mountain ranges till it enters the great groove that lies between the crystalline Alps and the limestone Prealps. It flows southwestward along the lowlying floor of this depression, which is known as the Combe de Savoie above Montmélian and lower down as Grésivaudan. It receives the Arly tributary at Albertville and later the Arc, which issues from a similar high Alpine valley, Maurienne, which approaches the Mont Cenis crossing into Italy. At Grenoble, where it is 650 ft. above sea level, the Isère turns northwest through a gap in the Prealps, between the Grande Chartreuse and Vercors blocks. As it enters this gap it receives the drainage of the southern end of the Alpine depression by its tributary the Drac, which has collected the Romanche, draining another high Alpine valley (Oisans). Beyond the gap, at Voreppe, the Isère turns again southwest to approach the Rhône across the rather infertile lowland of Bas Dauphiné, and enters the Rhône after passing Romans. The Isère is of no use for navigation, but it has been harnessed, together with its tributaries in the Alps, at many places for hydroelectric power, large quantities of which are transmitted from the mountain generating stations to supply the Lyons industrial area. Electrometallurgical and electrochemical industries have also been attracted to sites in the Alps. (Ar. E. S.)

ISERLOHN, an ancient town of Germany, *Land* (state) of North Rhine-Westphalia, which after the partition of the nation following World War II became part of the Federal Republic of Germany, is situated on the Baar 29 km. (18 mi.) S.E. of Dortmund by road. Pop. (1961) 55,257. Although the town was burned down in the 18th century, surviving ancient buildings include the Oberste Stadtkirche (14th century), with a carved altar of Flemish origin, Gothic paintings and other works of art; and Pankratius church (11th century) with a stained-glass window given by the British garrison in 1959. The museum and the former labour office were patrician houses of the 18th century and the modern Roman Catholic Trinity church is of interest. Railways and bus services link the town with Hagen, Dortmund, Schwerte and other towns. There are manufactures of machinery, lamps and hardware. The town is 700 years old and its industries go back to the middle ages. Its guild of armourers was already described as "ancient" in 1443. (M. Sc.)

ISFAHAN (Esfahan), a city of Iran and capital of Isfahan *ostan* (province), is situated at 5,200 ft. above sea level along the north bank of the Zayandeh Rud ("the life-giving river"), about 252 mi. S. of Teheran. Pop. (1956) 254,708. The name Isfahan (now pronounced Esfahan) is probably derived from the Old Persian word *cpâdhâna*, meaning "army camp" or "gathering place for armies." Ptolemy gives the name as Aspadana and in the Pahlavi texts it occurs as Spahan. An ancient quarter of the city was known as Gadh or Gay, which may perhaps have been identical with Strabo's Gabae, where the Achaemenid sovereigns often resided.

History and Architecture.—Little is known of Isfahan until Sasanian times. Queen Shushan-Dukht, the Jewish consort of Yezdigird (Yazdegerd) I (A.D. 399–421), is said to have settled a colony of Jews there in a suburb called Yahudiyeh (the establishment of this colony has also been attributed to Nebuchadrezzar, but this seems far less probable). The Shahristan bridge, which spans the Zayandeh Rud a short distance east-southeast of the city, dates from the Sasanian era; the piers are, however, all that remain of the original structure, the upper part having often been rebuilt. When the Arabs captured Isfahan in 642, they made it the chief city of the great central province of Al Jibal ("the mountains"), which covered much of the former country of Media.

Under the Buyid (Buwaihid) rulers of Persia (10th century), who rose to power when the temporal authority of the Abbasid caliphate was on the decline, Isfahan became extremely prosperous. In the middle of the 11th century the Turkish conqueror Togrul Beg, the founder of the Seljuk empire and dynasty, captured Isfahan and made it the capital of his vast domains, and under his grandson Malik Shah (1073–92) the city increased still further in size and splendour. In those days the central point of the city was a square, or rectangle, situated some distance to the north of the later Maidan-i-Shah. It was bordered on the north by the great Masjid-i-Jami, or cathedral mosque, which is still one of the chief architectural glories of the city; at the southern end was the Masjid-i-Ali, of which only the tall minaret remains of the original building. The Nizam al-Mulk, Malik Shah's chief minister and the patron of Omar Khayyam, added to the Masjid-i-Jami a dome chamber of great beauty. Not to be outdone, his rival, the Taj al-Mulk, then built close to it a smaller, but even more beautiful, dome chamber which is said to have attained "the perfection of architecture."

Isfahan, unlike Nishapur and many other Persian cities, escaped destruction by the Mongol hordes in 1220. Nearly a century later the Mongol ruler Ulja'itu endowed the Masjid-i-Jami with a magnificent mihrab or prayer niche. In 1388 Timur (Tamerlane) captured the city but spared its inhabitants. When, however, the Isfahanis revolted, he slaughtered about 70,000 and is said to have made a huge pyramid of their skulls.

Meanwhile, the craftsmen of Isfahan had been making themselves famous not only as metalworkers, weavers and builders but also as experts in the making of faïence-mosaic and polychrome tiles (*haft-rangi*) of the highest quality. Although Isfahan had, after the fall of the Seljuk dynasty, been eclipsed by other Persian cities such as Tabriz and Kazvin it regained its pre-eminent position during the Safawid period (1501–1736).

The city's golden age began in 1598 when Shah Abbas the Great (1587–1629) made it his capital in place of Kazvin. He largely replanned and rebuilt it, making it one of the largest and most beautiful cities of the world at that time. As a fitting centre for his capital, he created the immense Maidan-i-Shah, which measures 1,674 by 540 ft., the long axis running from north-northwest to south-southeast. At the southern end of the Maidan is the famous Masjid-i-Shah or royal mosque, begun in 1611 but not finished until after Shah Abbas' death. This building, decorated with enameled tiles of great brilliancy, has in the 20th century been carefully repaired. On the eastern side stands the Masjid-i-Shaikh Lutfullah, the low dome of which is adorned with dark blue and white arabesques on a *café au lait* background. The interior is covered with a combination of a faïence-mosaic and painted tile.

Shah Abbas, who dedicated this mosque to his saintly father-in-law, used it for his private devotions. On the western side of the Maidan is the Ali Qapu ("the lofty gate"), a high building in the form of an archway crowned in the fore part by an immense *talar* or covered balcony which served as an audience hall and as a vantage point from which the shah and his courtiers or guests could watch games of polo or gladiatorial combats below. This archway leads into the gardens of the former royal palace, which covers a large area with courts and pavilions, one of which, the Chihil Sutun ("forty columns"), was famous as a verandah and throne room of Shah Abbas. At the northern end of the Maidan is a tiled gateway leading to the Qaisariyeh or royal bazaar. The spaces between these buildings are filled by two-storied buildings with arched recesses, all of uniform design.

HANS WILD

ALI QAPU GATEWAY AND COVERED BALCONY, ISFAHAN

Nearly 600 yd. W. of the Maidan-i-Shah and connected with it by a side road is the Chahar Bagh ("four gardens"), the avenue which Shah Abbas made to give access to his capital from the south (the shah had to purchase four gardens in order to construct it). The Chahar Bagh runs southward to the Zayandeh Rud which it crosses by means of the fine bridge built by Allahverdi Khan, one of Shah Abbas' generals. The northern part of this avenue, which is nearly 1 mi. long and 200 ft. wide, consisted of two alleyways with a promenade between; down the centre was a watercourse with basins and fountains at intervals. Shade was provided by several rows of trees. The two roadways and the promenade remain, but the watercourse and fountains have disappeared.

Situated to the west of the southern extension of the Chahar Bagh is the Armenian suburb of Jolfa (Julfa). In order that the trade and industry of his new capital might flourish, Shah Abbas forcibly transplanted 6,000 Armenian families from the town of Jolfa in northern Persia and settled them in this suburb which was given the same name. The shah granted these capable and industrious Christians many privileges, including complete liberty of worship. A number of the churches built at that time, such as the Bethlehem church, are still standing. All Saviours cathedral was originally constructed on a small scale in 1606 and rebuilt in its present form in 1657. The cathedral, a typical domed structure, is decorated with paintings in the Italian tradition. Besides establishing the Armenians in Jolfa, Shah Abbas allowed the English and Dutch East India companies to set up factories in the city.

With the death of Shah Abbas I in 1629 the decline of the Safawid dynasty began, though it was arrested for a time under Shah Abbas II (1642–66). He was responsible for the building of the most beautiful of the Isfahan bridges, the Pul-i-Khwaju, which crosses the river nearly a mile to the east of the Allahverdi bridge. The Khwaju bridge was designed to serve also as a weir; by closing the sluices, the level of the river could be raised sufficiently to form an artificial lake in front of the palaces and pavilions that stood on either side for some distance upstream. An observant and painstaking French Huguenot jeweler, Jean Chardin (who was afterward knighted by Charles II and became a fellow of the Royal Society), spent ten years in Isfahan between 1664 and 1677, and in his *Voyages* gave a detailed and graphic description of the city as it was at its zenith. It had then, he said, 102 mosques, 48 colleges, 273 baths and no less than 1,802 caravansaries.

Situated on the east side of the Chahar Bagh, midway between its northern extremity and the river, is the Madraseh-ye-Madar-i-Shah ("school of the Shah's mother"), a religious college built by the mother of the pious but effete Shah Sultan Husain (1694–1722) and also known as the Madraseh-ye-Chahar Bagh. It is a fine building, with a tiled dome flanked by two minarets. In 1722, only a few years after its completion, the Ghilzai Afghans, under their savage leader Mahmud, defeated the Persian army a few miles to the east of Isfahan. They then invested the city and took it after a long siege, in the course of which more than 100,000 of the inhabitants perished from famine and pestilence. Mahmud deposed the feeble shah and mounted the throne of Persia himself. Isfahan has never fully recovered from this calamity. For many years the greater part of the city was a heap of rubble, and its population dwindled to a fraction of what it had been in its day of glory.

In the reign of Reza Shah Pahlavi (1925–41) an industrial quarter was built, for the most part on the south side of the Zayandeh Rud. Care was taken to ensure that this development did not mar the beauty of the city, this quarter being far removed from the principal historic monuments. Credit is due to Reza Shah for giving orders for the systematic repair of all the historic buildings, a task which was carefully carried out. Although now provided with a number of modern streets and shops, the city still retains its extensive and fascinating bazaars through which a visitor can wander for miles and imagine himself back in the time of Shah Abbas the Great. A medical college, administered by the ministry of national education, was founded in 1949.

Isfahan is on the main north-south highway from Teheran to Shiraz and the Persian gulf, and is linked by a road east and southeast to Yazd, Kerman, Zahedan and so to Pakistan.

The city is famous for its handicrafts, such as silverware, copperwork and brasswork, as well as for its pottery. The old art of tilemaking has been successfully revived in order to enable the ancient monuments to be adequately repaired. Isfahan is also well known for its rugs and its *qalamkars* (cotton fabrics handprinted with various designs). Modern industry is represented by the textile mills to the south of the river.

ISFAHAN OSTAN is situated in central Iran and bounded southwest by Khuzistan, west by the mountainous general governorship of Chaharmahal (formerly Bakhtiari) and that of Lorestan, north by Kashan (part of Mazanderan *ostan*) and by Semnan-Damghan general governorship, east by Khurasan, southeast by Kerman and south by Fars. The country is mountainous to west and south, but Isfahan city stands on the eastern edge of the Zagros mountains in a fertile basin irrigated by the Zayandeh Rud, the waters of which have been augmented by tapping (by means of a tunnel through the mountain) one of the main sources of the Karun river on the farther (western) side of the watershed. The climate is relatively temperate, without great extremes of heat or cold.

The area of the *ostan* is 76,216 sq.mi. (197,403 sq.km.). In 1956 the population was 1,513,577 and was on the increase. The *ostan* is divided into six *shahrestans* (districts): Isfahan, Ardestan, Na'in, Yazd, Shahreza and Faridan (or Daran). Yazd (pop. [1956] 66,484) is the second largest city in the *ostan* and has a

HANS WILD

THE FERTILE BASIN OF ISFAHAN

substantial Zoroastrian community; next are Najafabad (30,422) and Shahreza (formerly Qomisheh, 29,311).

The Isfahan *shahrestan* is the most fertile area. It is well watered by the Zayandeh Rud and canals supplied by it, as well as by many wells. A considerable amount of grain is grown. Apart from the industries of Isfahan city, Yazd has carpet- and silk-weaving and shawlmaking industries and the manufacture of footwear known as *givehs* (similar to the Spanish *alpargata*).

(L. Lo.; X.)

ISHII KIKUJIRŌ, Viscount (1866–1945), Japanese diplomat who effectively championed cautious expansion of Japan and co-operation with the west in the decades immediately before and after World War I. Born in a village in Chiba, he was adopted by the Ishii family and sent to Tokyo university. He graduated in law in 1890 and entered the foreign ministry. After ten years of service in France, Korea and China he was recalled to Tokyo. In 1907 he was sent to the United States to investigate the rising anti-Japanese sentiment in Vancouver and San Francisco. He contributed to the "gentlemen's agreement" between Japan and the United States, by which the Japanese government promised to withhold passports from labourers intending to migrate to the United States.

After two years in Paris as ambassador Ishii was appointed Japanese foreign minister, 1915–16, and in 1917 was sent on a special mission to Washington, D.C. During these years Russian approval of Japan's new gains on the continent of Asia, resulting from the "21 demands" negotiations with China and seizure of German rights in Shantung, was secured in the secret agreement of 1916. (*See* China: *The Republic: Foreign Relations* [*1911–17*].) A somewhat ambiguous American approval of Japan's special interests in China was given in the Lansing-Ishii agreement of 1917, but Japan affirmed its respect for the open door policy and for the independence and territorial integrity of China.

From 1920 to 1927 Ishii represented Japan at Paris and at the League of Nations, and in 1933 he attended the London Economic conference. Although appointed to the house of peers and the privy council in 1928, he gradually withdrew from active political life. He died in an American bombing raid on May 25, 1945.

Ishii's grasp of modern international relations, his defense of Japan's imperial interests and his loyalty to the cause of international co-operation are well represented in his memoirs, *Gaikō yoroku,* which have been partially translated into English as *Diplomatic Commentaries.* (J. W. Mo.)

ISHIKAWA, a *ken* (prefecture) of western Honshū in central Japan noted for its textile industry, faces the Sea of Japan. Area 1,619 sq.mi.; pop. (1960) 973,418. In the southeastern part lies the western stretch of the Hida range. Although snowfall is abundant, temperatures are not low. Agriculture is characterized by the predominance of paddy fields, comparatively large landholdings per household and the progress of mechanization. Products include silk and rayon, *Yamanaka* and *Wajima* lacquerwares and the traditional *Kutani* china. The capital, Kanazawa (pop. [1960] 298,972), retains the characteristic features of a castle town. (R. B. H.)

ISHIM, a river of the U.S.S.R., a tributary of the Irtysh, 1,807 km. (1,123 mi.) long and draining a basin of 52,896 sq.mi. It rises southeast of Akmolinsk (North Kazakhstan *oblast*) in the Kazakh hill country and flows westward in a narrow, rocky valley, with frequent rapids. West of Atbasar the Ishim swings north across the level west Siberian lowland (Ishim steppe) to join the Irtysh 645 mi. from its mouth. In these middle and lower courses the river meanders greatly and is 80–130 yd. broad. The average annual discharge is 1,519 cu.ft. per second, with a very marked spring maximum from snow melt, which supplies 90% of the annual flow. Two large towns, Akmolinsk and Petropavlovsk, are built on its banks, but it is navigable only as far as Vikulovo.

Ishim Town stands on this river where it is crossed by the Tyumen-Omsk railway, in Tyumen *oblast.* Pop. (1959) 47,800. It is an agricultural centre with flour milling, distilling and butter-making industries. (R. A. F.)

ISHMAEL ("May God hear"; in the Douai version of the Bible, Ismael; Arabic Isma'il) is a significant figure in both the Old Testament and the Koran. He was the son of Abraham (Arabic Ibrahim) and his Egyptian concubine, Hagar (Hajar). According to the story in the Book of Genesis, through the jealousy of Abraham's wife Sarah (Sara), mother and son were driven from the tribe and saved from death by thirst through the miraculous discovery of a well (Gen. xxi. 8–20). Ishmael grew up an archer (xxi. 20) and a "wild ass of a man" (xvi. 12), living to the south and east of Palestine. He is the ancestor of 12 tribes of desert rangers (xxv. 12–18). "Ishmael," therefore, is used in a wide sense of the wilder, roving peoples encircling Canaan from the northeast to the south, related to but on a lower rank than the "sons" of Isaac. It is practically identical with the term "Arabia" as used by the Assyrians. Nothing certain is known of the history of these mixed populations. They are represented as warlike nomads and with a certain reputation for wisdom (Baruch iii. 23). Not improbably they spoke a dialect (or dialects) akin to Arabic or Aramaic.

According to Muslim tradition (which is acquainted with the story in Gen. xxi), Isma'il is the progenitor of *al-musta'riba,* the "arabicized" north Arabian tribes. The Koran (ii. 127) states that he helped Ibrahim to raise the foundations of the Ka'ba (*q.v.*).

ISHTAR (Sumerian Inanna), the great goddess of the Sumero-Akkadian pantheon, in name and attributes identical with Astarte. The meaning of her name is uncertain: a plural form of it, *ishtarati,* denotes "goddesses." Written ideographically in Sumerian, it is read Inanna, which may derive from Nin-anna, "Lady of Heaven." The Akkadian form Ishtar, first written syllabically about 2000 B.C., may derive from *Esh-tar.* How the early Semites in Sumer-Akkad thought of Ishtar is not clear, but Hammurabi, like the earlier Sumerian ruler Gudea, styles her "lady of battles." As such in Babylonia and Assyria she is represented on a lion, with a weapon in her hand. Ishtar is also the goddess of love. A lover of mortals, whom she exalts, she delights in bodily love, including prostitution (which was part of her cult, as Herodotus records). As identified with Venus, the morning star, she is represented or accompanied by a star with 6, 8 or 16 rays within a circle.

The morning is child of the night and of its god Sin, the moon. Inanna-Ishtar is, accordingly, daughter of Sin; she is also sister of Shamash, the sun-god, and forms with these deities the secondary cosmic triad. An earlier Sumerian myth, however, makes her the daughter of Enki (*see* Ea), god of Eridu, and goddess of Uruk (biblical Erech). From her father, Enki, she receives the divine laws, which she takes to Uruk, where her temple is Eanna, "House of Heaven" (or possibly "of the Date Clusters").

Inanna-Ishtar figures in the myths of the flood and of Gilgamesh, but chiefly in the "Descent of Ishtar to the Underworld," of which both an Akkadian and a shorter Sumerian version survive. The queen of the underworld, Ereshkigal (*q.v.*), is here the sister of Ishtar. The cult of Ishtar was universal in the ancient near east. She was the universal goddess par excellence, whom kings, native and foreign, delighted to honour in capitals and major cities at all periods of Assyro-Babylonian history.

See Babylonia and Assyria: *Religion: Sumerian Pantheon: Herding Regions* and articles on related figures: Aphrodite; Astarte; Atargatis; Great Mother of the Gods; *see* also references under "Ishtar" in the Index.

ISIDORE, SAINT, of Seville, in Latin called Isidorus Hispalensis (*c.* 560–636), Spanish encyclopaedist, theologian and historian, probably belonged to a family from Cartagena. He succeeded his brother Leander as archbishop of Seville in A.D. 600 and headed the Spanish synod of Toledo in 633. His summary of all knowledge accessible to him, *Etymologiae* or *Origines,* remained for many centuries one of the most important reference books: almost 1,000 medieval manuscripts of it are still in existence. In its 20 sections, Isidore handed down to posterity much that he had extracted from works of previous encyclopaedists (*e.g.*, Cassiodorus), specialists and Latin writers of all kinds, on the seven liberal arts, medicine, law, history, church matters, theology,

anthropology, zoology, cosmology, psychology, architecture, agriculture, etc.

Other special treatises by him were devoted to linguistic matters (*Differentiarum libri* and, perhaps, *Synonymorum libri*), to natural science and cosmology (*De natura rerum* and *De ordine creaturarum*) and to history (a continuation of Jerome's and Gennadius' *De viris illustribus;* a re-elaboration and continuation of Jerome's history, under the title *Chronica maiora;* and a *Historia Gothorum, Vandalorum et Sueborum*). As a theologian, he wrote *Quaestiones in Vetus Testamentum;* biographies of 86 persons of the Bible (*De ortu et obitu patrum*); a handbook of morals and theology in the form of a collection of *Sententiae,* mainly based on Gregory the Great's *Moralia;* a treatise *De fide catholica contra Judaeos; De haeresibus;* a liturgical work *De ecclesiasticis officiis;* and a *Regula monachorum.* It is not certain whether the original edition of the *Hispana* (*see* CANON LAW), sometimes known as the *Collectio canonum Isidoriana,* was in fact produced by Isidore, though it seems to have been compiled in Spain in his time. For the *Pseudo-Isidoriana* of the 9th century, *see* DECRETALS, FALSE.

Isidore was canonized in 1598 (feast day April 4) and formally declared a doctor of the church in 1722.

ISIDORE OF ALEXANDRIA (*fl. c.* A.D. 500), Neoplatonic philosopher, succeeded Marinus (the successor of Proclus) in the headship of the school of Plato at Athens. His main claim to distinction is that he was the teacher of Damascius, the last and one of the greatest of the Neoplatonic successors of Plato, who wrote Isidore's life in the customary enthusiastic manner of Neoplatonic biography.

Another Isidore, of Gaza, was one of the philosophers who accompanied Damascius to Persia after the closing of the schools of Athens in 529.

ISIN, an ancient city in Babylonia, probably to be identified with a large mound about 20 mi. E.S.E. of Diwaniyah in modern Iraq. An independent dynasty was established there *c.* 2030 B.C. by Ishbi-Irra, "the man of Mari." He originated a line of Amorite rulers of whom the first five claimed authority over Ur, which ceased to be paramount in Sumer after Ibbi-Sin, the last king of its 3rd dynasty, had been taken prisoner by the Elamites. Shulilishu, the second king of Isin, however, raided Elam and restored to Ur the statue of the moon-god Nanna, which had been carried off to Anshan. The fourth king of Isin, Ishme-Dagan (1966–46 B.C.), undertook substantial rebuilding of temples in Ur, and his son Enannatum dedicated a finely carved diorite statue to the moon-goddess Ningal, which was discovered *in situ.* The fifth of the Isin rulers, Lipit-Ishtar (1946–36 B.C.), is justly famous as having published a series of laws in the Sumerian language anticipating the code of Hammurabi (*q.v.*) by more than a century. Thereafter Isin became subject to the neighbouring city of Larsa (*q.v.*). There was a revival of the city's fortunes between *c.* 1150 and 1020 B.C. under its 2nd dynasty, a number of whose kings exercised authority in Babylonia. *See* also BABYLONIA AND ASSYRIA.

ISINGLASS, a pure gelatin derived from the air bladders, or sounds, of fish. Russian isinglass, obtained from the sounds of various species of sturgeon, is considered the best. However, a satisfactory product is yielded by the sounds of catfish, carp, hake, cod, squeteague and other fish. Important amounts of isinglass are supplied by the U.S.S.R., the United States, Canada, Brazil, Venezuela, India, Penang and the Philippines.

In processing, the sound is cleansed and soaked in hot water to free it of mucous membrane. It is then cut open to expose the pure, lustrous inner membrane and dried. The outer membrane is removed from the dried sound by beating and rubbing. In open form the product is called "leaf" isinglass. Folded over it is termed "book" isinglass. Trimmings from leaf and book isinglass are compressed into "cake" isinglass. It may also be produced in sheets 6 to 8 in. wide and $\frac{1}{8}$ to $\frac{1}{4}$ in. thick or in ribbons $\frac{1}{64}$ in. thick.

The product has several commercial uses. By trapping in its gelatinous fibres substances causing turbidity, it serves as a clarifying agent in cider, wines and malt beverages. Isinglass dissolved in alcohol or acetic acid produces strong cements for mending pottery, glass, etc. Combined with gum, isinglass is utilized as a size for textiles, imparting lustre and stiffness to the material, and is also employed in various waterproofing compounds. (E. L. Y.)

ISIS, the Greek form of the Egyptian word meaning throne. In hieroglyphic writing the picture of the throne followed by the feminine signs stands for the name of the goddess, and the root meaning of the name is therefore the throne-woman; *i.e.,* the queen. In ancient Egypt inheritance of the throne was strictly matrilineal, descending from mother to daughter; the king became king only by right of marriage with the queen, who, as a royal ruler, was worshiped as a goddess.

EGYPTIAN STATE TOURIST ADMINISTRATION

RELIEF OF ISIS IN THE TEMPLE OF KALABSHA, LOWER NUBIA

The tradition that Isis and Osiris were not indigenous deities but came into Egypt from the north is probably founded on fact, and may record the introduction of a higher type of civilization and a new religious outlook. Little is known of her early cult for the objects and the inscriptions of the early periods are almost entirely funerary, Osiris and Anubis being the chief deities invoked. Even in the Pyramid texts—the earliest extant religious literature, first inscribed on the walls of the burial chambers of King Unas (at Saqqarah) in the 5th dynasty and continued by the kings of the 6th dynasty—intended solely for the protection of the dead king in the other world, Isis is hardly mentioned except as the mourner for Osiris. But the legends about her suggest that she was in origin an independent deity, for there are traces in them of contacts of her cult with those of Set (Setekh), Anubis, the northern Horus, the cobra-goddess Wadjit and the sun-god Re (Ra). In her aspect as the wife of Osiris she is the chief actor, but only after his death: she finds his corpse at Byblos, she finds the fragments of the dismembered body scattered throughout Egypt, she is the chief mourner at the funeral, she unites the fragments of the body and, by her divine power, brings Osiris to life again. In this connection Herodotus rightly equates her with Demeter (*q.v.*), for Osiris, as his ritual at Abydos shows, was the grain. Her chief aspect is that of the great enchantress, whose power transcended that of all other deities, even that of the sun-god himself. This magical (*i.e.,* divine) power is emphasized in the legend of the bringing of Osiris back to life, and she was invoked in all forms of illness, for even Anubis, the god of death, was subject to her. Her aspect as a mother was not specially important till the New Empire, for motherhood was one of the functions of all goddesses, but in the later periods she is commonly represented with "Horus the child" (Harpocrates) on her lap. It is not known when the name Horus was given to the child, but it is probably due to the similarity of the name that the northern Horus came to be regarded as the son of Osiris and Isis grown to manhood and making war on Set, the enemy of Osiris. In this war Isis greatly assists Horus by her irresistible magical spells (*see* HORUS).

Representations of the gods and the temples for their worship

are rare till the Middle Kingdom, probably because, as the Pharaoh was regarded as divine, his statues were the images of the deity while the mortuary and pyramid temples were for his worship. Representations of Isis are therefore infrequent until the New Empire, after which they become increasingly common. She was the most popular goddess from the time of Psamtik I (663–610 B.C.) till the coming of Christianity, by which time the naturalistic type of art had so ousted the old traditional Egyptian artistic conventions that it is sometimes difficult to distinguish between pagan and Christian figures of a mother and child.

Isis is represented as a woman with the sign of the throne on her head. As a mourner she kneels at the foot of the coffin, but as an independent goddess she is enthroned. As a rule she is represented as entirely human, but in the late periods she is sometimes equated with the goddess Hathor and wears the cow's horns on her head. Her cult seems to show that her dealings were with human beings rather than with crops: as mourner she was the chief person in all rites connected with the dead; as enchantress, she cured the sick and brought the dead to life; and as mother, she was herself a life-giver. Her cult appealed strongly to the Greeks and the Romans and, when Egypt came under Roman rule, it spread across Europe. The chief centre of her worship in Europe was in Rome, but smaller temples were founded elsewhere, even as far away as Britain. *See* OSIRIS; *see* also references under "Isis" in the Index.

(M. A. M.)

ISKENDERUN (formerly ALEXANDRETTA), a port, administrative centre of an *ilce* (district) and the largest town in Hatay *il* (province), Turkey, is situated on the eastern shore of the Gulf of Iskenderun, 27 mi. N. of Antioch (Antakya) and about 60 mi. S.E. of Adana. Pop. (1960) 63,736. Lying on an alluvial plain below the Amanus mountains (Nur Daglari), the town is modern with fine buildings and avenues decorated with subtropical plants. It is also a winter resort and has a military base. Iskenderun preserves the name but probably not the exact site of the city, Alexandria ad Issum, founded to commemorate Alexander the Great's victory over the Persians at Issus (333 B.C.). The name "Little Alexandria" may date from the 4th century A.D. The port was the main outlet for overland trade from Iran and India until the construction of the Suez canal. Its rapid growth after it was returned by France to Turkey in 1939 (*see* HATAY) was due to improved port facilities. It serves as a gateway to eastern and southeastern Anatolia and is connected by rail and road with other parts of Turkey. A main road to the south, crossing the Amanus range through the historic Belen pass, leads to Antioch, northern Syria (Aleppo) and thence Iraq. (N. TU.; S. ER.; E. TU.)

ISLA, JOSÉ FRANCISCO DE (1703–1781), Spanish satirist and Jesuit preacher whose picaresque satirical novel, *Historia del famoso predicador fray Gerundio de Campazas, alias Zotes* (1758) was so successful that the first printing was exhausted in a day or two, was born in Vidanes, León, but after his order was expelled from Spain in 1767 he lived mostly in Bologna, Italy, where he died. In *Fray Gerundio* . . . he aims at annihilating by ridicule the popular mendicant preachers who held large audiences by histrionic devices and by stuffing their absurd sermons with low jests, strained metaphors, learned references and Latin quotations. He was so successful that *"gerundio"* became used as a noun and adjective to describe pseudo-learned preachers or grandiloquent sermons, or, more generally, a bombastic and pedantic style. The mendicant orders denounced the novel to the Inquisition, which suspended the second printing of Part I (1760) and of Part II (1770), together with all the pamphlets discussing the work. At the end of the century, however, Isla was better known for his translation of Alain Le Sage's *Gil Blas de Santillana* (1787, posth.), mainly because of his unfounded claim, which provoked a long controversy, that he was restoring to its native country and language a work stolen from the Spanish.

See B. Gaudeau, *Les Prêcheurs burlesques en Espagne au XVIII^e siècle* (1891); F. Cordasco, "Llorente and the Originality of the Gil Blas," *Philological Quarterly* (1947). (EH. F. H.)

ISLAM (repeatedly used in the Koran in the sense of "surrender to God's will") is the name of the religion promulgated by Mohammed (*q.v.*). One who accepts Islam is a Muslim. There are no absolutely reliable figures for the Muslim population of the world, but the most reasonable figure is between 370,000,000 and 400,000,000. There is a striking unity or similarity of sentiment and attitudes among all the Muslims both within themselves and vis-à-vis the non-Muslim world, thus justifying the concept "Muslim world"; nevertheless, there are equally striking cultural and religious differences among different regions—the Arabs and the arabized Africans; the Turks and the Turkic central Asians; the Persians; the Pakistano-Indians; the Malay-Indonesians; and the Chinese. The most prominent fact of the 20th century for the Muslim countries is the strenuous and progressively successful endeavour to preserve or achieve independence from colonial rule, and in these endeavours the religious Islamic sentiment has played a fundamental role. For the history of the spread of Islam, see CALIPHATE and other articles referred to there.

For the Muslims, the Koran (*q.v.*) is the Word of God, confirming and consummating earlier revealed books and thereby replacing them; its instrument or agent of revelation is the Prophet Mohammed, the last and most perfect of a series of messengers of God to mankind—from Adam through Abraham to Moses and Jesus, the Christian claims for whose divinity are strongly rejected. Indeed there is no people to whom a prophet has not come. Although Mohammed is only a human creature of God, he has nevertheless an unequaled importance in the Koran itself which sets him only next to God as deserving of moral and legal obedience. Hence, his sayings and deeds (Sunna) served as a second basis, besides the Koran, of the belief and practice of Islam.

The Koran (which, for the Muslim, is the miracle par excellence of Mohammed, unsurpassable in form as well as in content) is a forceful document basically expressing an *élan* of religious and social justice. The early chapters (suras) of the Koran, reflecting Mohammed's grim struggle against the Meccans, are characterized by grave warnings of the imminent judgment, while the later suras, of the Medina period, are chiefly directed to regulating the internal and external affairs of the young Muslim community-state, besides narrating the stories of the earlier prophets.

The koranic theology is rigorously monotheistic: God is absolutely unique—"there is nothing like him"—omnipotent, omniscient, merciful. Men are exhorted to obey his will (*i.e.*, to be Muslim) as is necessarily done by all inorganic objects. Special responsibility is laid on man who willingly, although with his characteristically foolish pride, accepted "the trust," refused by all creation. Besides human beings and angels, the Koran speaks of the jinn, both good and evil, to whom sometimes the devil is represented as belonging (*see* JINNI).

MUSLIM THEOLOGY

The Creed.—The creed consists of five articles of faith: (1) belief in one God; (2) in angels; (3) in the revealed books; (4) in the prophets; and (5) in the Day of Judgment. To these was added, during the early development of the dogma, the belief in God's predetermination of good and evil. The profession of the faith (*shahada*) is: "There is no God but God and Mohammed is his apostle."

The Five Pillars.—These are the five obligatory duties: (1) reciting the profession of faith; (2) prayers; (3) paying of the *zakat* tax; (4) fasting; and (5) pilgrimage to Mecca.

The profession of the faith must be recited, at least once in a lifetime, aloud and correctly, purposively, with a full understanding of its meaning and with an assent from the heart.

The obligatory worship of God consists of five daily prayers preceded by necessary ablutions. Although the Koran (xxx, 17–18) expressly mentions only four, the actual practice of the Prophet was five: before sunrise, just after noon, in the late afternoon, immediately after sunset, and the last one, about two hours later. All these prayers are public and collective, although under necessity individual prayers are allowed. Each service, led by an imam, is offered with one's face toward the Ka'ba (the sanctuary at Mecca) and consists of two or more genuflection units. All the different physical postures and the materials to be recited, silent or aloud, have been fixed by tradition, including the first sura of the Koran which is to be recited in each unit, followed,

in some units, by another passage from the Koran. Under special circumstances such as illness, journey or war, modification or limited postponement is allowed. On Fridays, instead of the prayer just after noon, a congregational prayer is offered including a sermon (*khutba*) declaimed from the pulpit (*minbar; see* below). Special congregational prayers are offered in the middle of the morning on the two festival days called *'ids*, one immediately following the month of fasting and the other following the pilgrimage. Although not ordained as an obligatory duty, individual devotional prayers, especially during the night, are emphasized and have been carried to extreme limits by the Sufis.

The obligatory tax called *zakat* ("purification"; *i.e.*, that the payment of which renders the remaining property religiously and legally legitimate) is payable on food grains, money, etc., each year after one year's possession. The amount varies for different categories. Thus, on grains and fruits it is 10% if watered by rain, 5% if watered by irrigation; 2.5% on money is prescribed. Money so obtained is to be spent primarily on the poor and the needy. In olden times the collection and expenditure of *zakat* was a function of the state; since the general breakup of the Muslim religio-political power, it has been left to the individual. Besides these legal alms, the payment of charities (*sadaqat*) is stressed in the Koran and the Tradition.

The fast has been laid down (Koran ii. 183–185) for the entirety of the month of Ramadan "in which the Koran was sent down." The Koran also says (iii. 1) that "it was sent down on the Night of Determination [or Power; *lailat al-qadr*]," and Muslims generally observe this night during the night of 26–27th Ramadan. For a person who is sick or on a journey "another number of equal days" is prescribed. Feeding of one poor man is also required from "those who can afford it." The fast, during which all eating and drinking is forbidden, starts at daybreak and ends at sunset. (*See* also RAMADAN.)

The fifth pillar is the pilgrimage (*hajj*) to Mecca, which it is incumbent on every Muslim to perform once in a lifetime provided he or she can support himself during the journey and can also arrange for the provision of his dependents during his absence. The pilgrimage ceremonial begins every year on the 7th and ends on the 10th of the month of Dhu 'l-Hijja. When the pilgrim is about six miles from the holy city, he enters upon the state of *ihram;* he casts off, after prayers, his ordinary clothes and puts on two seamless garments; he walks almost barefooted and neither shaves, cuts his hair nor cuts his nails. The principal activity consists of a visit to the Sacred mosque (*al-Masjid al-Haram*); the kissing of the Black Stone (*al-Hajar al-Aswad*); seven circumambulations of the Ka'ba, three times running and four times slowly; the visit to the sacred stone called Maqam Ibrahim; the ascent of and running between Mt. Safa and Mt. Marwa seven times; the visit to Mt. 'Arafat; the hearing of a sermon there and spending the night at Muzdalifa; the throwing of stones at the three pillars at Mina and offering sacrifice on the last day of *ihram*, which is the *'id* of sacrifice (*'Id al-Adha*). (*See* also MECCA.) At other times in the year, it is considered meritorious to perform the lesser pilgrimage (*'umra*), which, however, is not a substitute for the *hajj*.

Development of the Shari'a.—The most important and fundamental religious concept of Islam is that of the *shari'a* which literally means a "path to the watering place" but in its religious application means the total way of life as explicitly or implicitly commanded by God. The word has been used in the Koran, which sometimes suggests that different religions have different *shari'as* but at other times that all religions have fundamentally one *shari'a*. The concept, as formulated by Muslim religious teachers, includes both the doctrine or belief, and practice or the law (*fiqh; see* ISLAMIC LAW). But historically the formulation and systemization of the law took place earlier than the crystallization of the formal theology. This, as shown below, had far-reaching consequences for the future development of Islam.

Bases of the Shari'a.—The formulation of the *shari'a* rests on four bases (*usul*):

1. The Koran.

2. The Sunna (the Way) of the Prophet as recorded in the Tradition (Hadith). Six collections of the Tradition, known as "the six genuine ones" (*al-sihah al-sitta*), are regarded by the majority of Muslims as especially authoritative. These are (*a*) the *Kitab al-Jami' al-Sahih* of al-Bukhari (*q.v.*), which is the most celebrated and most scrupulously compiled; (*b*) the *Sahih* of Muslim ibn al-Hajjaj (*q.v.*) with an introduction on the science of Tradition; (*c*) the *Kitab al-Sunan* of Abu Dawud (817–886); (*d*) the *Jami' al-Sahih* of al-Tirmidhi (*q.v.*); (*e*) the *Kitab al-Sunan* of al-Nasa'i (830–915); and (*f*) the *Kitab al-Sunan* of Ibn Maja (824–886). The Tradition, which constitutes the history of Islam for its earliest period and which is the mother of Muslim historiography, is under attack by certain modern reformist Muslim groups. (*See* also HADITH.)

3. The third basis of the *shari'a* is *ijma'* or the universal agreement which has been materially perhaps the most important factor in defining what the Koran and the Sunna mean (*i.e.*, in formulating the doctrine and practice of the Muslim community) but which itself has curiously remained the least clearly formulated religious institution of Islam. Its full nature and implications have never been adequately analyzed either in medieval Islam or by modern scholarship.

Two important points must be borne in mind. (*a*) First, although this is not inherent in the concept itself, *ijma'*, in the pre-modern Islamic usage, has always had reference to the past, near or remote, and does not denote a contemporaneous agreement. It is, therefore, a part of the mechanism of traditional authority and does not mean a present and ongoing democratic religious operation except to the extent of the present recognition and acceptance of the past. Since the majority of the companions of the Prophet lived in Medina, the beliefs and practices of the Medina community at an early date gained authority through the *ijma'* principle. In the modern Muslim usage of the term, however, *ijma'* has come to mean a democratic institution opposed to traditional authority. (*b*) Second, and consequently, far from working as a monolithic principle of unique standardization, *ijma'* came to operate as a principle of toleration of different traditions within Islam. For, in addition to the Medina community, a school grew up in Iraq soon after the early Muslim conquests. Moreover, the converts to Islam had brought with them many of the practices and even the beliefs of pre-Islamic times. These, at first tolerated probably in the hope of gradual assimilation, later became recognized as valid through the *ijma'* conception, which came to mean the acceptance on the part of each section of the community of the opinions of the other sections.

Yet it would be wrong to think of *ijma'* exclusively in this sense of different but tolerated traditions. The apparently subsidiary sense of *ijma'* noted above—viz., the recognition and acceptance of the past as authoritative—is itself an activity, which has produced a fundamental core of ideas and conduct; it is formally secondary to *ijma'* in the sense of an irrevocable past, but materially it is even more basic. Even the so-called *ijma'* known as the *ijma'* of the doctors and thinkers of Islam is, in the last analysis, subject to the *ijma'* of the community. This is supported by a prophetic tradition which says "my community shall never agree upon an error."

4. The fourth principle of the *shari'a* formulation, known as *qiyas* or analogical reasoning, is the genuine basis of interpretation and thought (*ijtihad*) in Islam. It is this which makes progressive *ijma'* possible. Its earlier form was personal thought and opinion (*ra'y*), which was criticized by many eminent traditional authorities as "arbitrary." There are discussions in Muslim methodology as to the nature and scope of this activity, which concerns itself with the deduction of new beliefs and practices on the basis of analogy with past practices and beliefs. The right of original thinking (*ijtihad*) in medieval Islam was restricted by the orthodox to the first few generations of Islam, although by the Shi'a (*see* below) it continued to be vested in their doctors (*mujtahids*). But even medieval Islam witnessed powerful rebels like Ibn Taimiya (*q.v.;* the Wahhabi movement arose under the influence of his ideas), who claimed the right for themselves and whose influence has increased manifold, supported by modernists.

Sciences of the Shari'a.—There are four sciences known as the

sciences of the *shari'a (al-'ulum al-shar'iya)*: the prophetic Tradition (Hadith), the koranic exegesis *(tafsir)*, theology *(kalam)* and law *(fiqh)*. The first two are the materials for theology and law. In the four schools of law, the Hanafi, the Maliki, the Shafi'i and the Hanbali *(see* Islamic Law), which took shape early—during the first two centuries of Islam—law and theology were a unity and were not separated, although theology at that time was merely a statement of the doctrine. But whereas the legal systems thus erected remained to satisfy practical exigencies of the vastly expanded Muslim empire, and have continued down to the present, the doctrine was exposed to wide and strong discussions, criticisms and interpretations in the mixed milieu of Iraq (1) between Muslims on the one hand and representatives of the Christian, Gnostic, Buddhist and Hellenic elements on the other, and (2) within Islam between the rationalizing schools of the Mu'tazilites on the one hand and the orthodox fundamentalists like Ibn Hanbal on the other. As a result, a cleavage occurred between the law and the doctrine, and the former, which ideally presupposed the latter as its base, came not only to be an independent discipline but to claim for itself the title of the science of the *shari'a* par excellence, and was even identified with the *shari'a* itself. Thus *fiqh*, which originally meant an understanding of the entire range of the faith, came to be applied to law alone.

Early Theological Controversy.—The earliest theological controversies, which were probably instigated by contacts with Christians, centred around the questions of human free will over against God's predestination (both of which appear in the Koran) and of the nature of God's unity—whether his attributes were eternal entities beside his essence. Those who championed the freedom and efficacy of the human will were called Qadarites; the predestinarians asserted otherwise. The Qadarite doctrine was considered to be heretical in the beginning, and one of its early exponents, Ma'bad al-Juhami, was executed in 699. But after the Omayyads, the free-will idea gained popularity. By that time there had arisen under Wasil ibn 'Ata' the Mu'tazilite (the "seceders") school which, besides championing the freedom of the human will, held as its corollary that it was against divine justice either to punish a good man or pardon an unrighteous one. They also denied the attributes of God over and above his essence. Hence they called themselves "the people of Justice and Unity (of God)." Above all, they believed in the autonomy of reason over against revelation and in the supremacy of reasoned *('aqli)* faith over against traditional *(naqli)* faith. They also declared the Koran to be a created thing—a consequence of their denial of attributes. Under the caliph al-Ma'mun, a great patron of learning and culture, Mu'tazilism was adopted as the state creed and its chief orthodox opponent, Ibn Hanbal *(q.v.)*, who rejected reason altogether in matters of faith, was persecuted. But during the caliphate of al-Mutawakkil, orthodoxy was rehabilitated and the Koran was declared uncreated.

The crystallization of the orthodox creed took place in the 10th century at the hands of Abu 'l-Hasan al-Ash'ari, who carried it to victory against Mu'tazilism *(see* Ash'ari, al-). Until his conversion to orthodoxy, or until his explicit formulation of orthodoxy, al-Ash'ari had belonged to the Mu'tazilite school and was a pupil of the famous Mu'tazilite master al-Jubba'i. But he rebelled against them, using their own weapons of dialectical theology. His system is essentially a mediation between the rationalization of the Mu'tazilites and the anthropomorphism of the traditionists. He reaffirmed the attributes of God but taught that these are unlike the human attributes of the same name, that they exist neither as being identical with God's essence nor as being different from it. He also taught that God will be visible to the sight of the faithful on the Judgment Day, as the Koran has it, but that its manner we do not know *(bi-la-kaif)*. On the question of freedom of the human will and its efficacy, he affirmed the former but denied the latter. The substance of his teaching is that human volitional acts are morally attributable to man, who is responsible for them, and ontologically attributable to God, who is the sole productive cause of all events. At first looked upon with suspicion and confounded with Mu'tazilism, Ash'arism slowly gained ground in Iraq and Persia—especially due to the influence of the great al-Ghazzali—and thence spread westward to Spain and Egypt under the Ayyubids and the Mamelukes and to Africa under the Almohad Ibn Tumart (1130).

After al-Ash'ari, the system was developed by Abu Bakr al-Baqillani, the qadi (d. 1012). Its chief subsequent criticisms and modifications were centred on the question of the efficacy of the human will. While Ash'arism has remained the chief umbrella symbol on the formal side, the content of theology was influenced later from other quarters, primarily philosophical. A system of theology closely resembling that of al-Ash'ari but somewhat more liberal is that of the Hanafi al-Maturidi (d. 944). In later individual writers Maturidism and Ash'arism have freely interacted. There has also existed a literalist (Zahiri) school of theology whose most famous exponent was the Spanish Ibn Hazm *(q.v.)* but which has not claimed many adherents.

Shari'a and Non-Shari'a Disciplines.—The main function of the thus established orthodox creed was to restore doctrinal equilibrium; it was more or less formal, and the theological base on which it was supported was also scholastic and formal. In the educational institutions that grew up all over the Muslim world theology and law were taught, but, whereas theology was learned for defensive and formal purposes, law came to be looked upon as the sole content of the *shari'a*, even though the theologian continued to contend that theology was the highest discipline. In the meantime both, living on sufferance of one another, were faced with real and strong forces in the concrete life of the people. Philosophy *(see* Arabic Philosophy), based on the spirit of free inquiry into the nature of things, threatened theology, and Sufism, rooted in the state of the heart, challenged law.

Sufism *(q.v.)*, yearning for a personal union with God, found the externalities of the law, divorced from a personal theology, very unsatisfactory and increasingly opposed its own way *(tariqat)* and its goal *(haqiqat)* to the *shari'a;* it similarly opposed its intuitionism *(ma'rifat)* to the rational deductions of formal theology. The main stream of the Sufis strove to remain within orthodoxy and declared that the observance of the *shari'a* law was indispensable; indeed, from the early period they had attempted to develop a scheme of partly antithetical and partly complementary categories ("annihilation and restoration," *fana' wa baqa';* "intoxication and sobriety," *sukr wa sahw*, etc.) to achieve a synthesis of the external and the inner. But the opposition of these two aspects continued to be emphasized. Later, under the influence of speculative mysticism, Ibn 'Arabi *(q.v.)* produced a system which created a complete chasm between the law and Sufism. In societies, such as Indian Islam, that had a strong pre-Islamic heritage of mysticism, this chasm became much wider. Sufism developed into dervish *(q.v.)* orders that remained influential until very recent times; their influence has waned sharply in the modern period, even though in the middle east and especially in Africa they combated the European penetration. In Turkey they were officially disbanded by the regime of Mustafa Kemal Ataturk.

Based upon a Neoplatonized version of Aristotelianism, a powerful, although individual philosophical movement arose in the 9th century. Its great figures—al-Farabi *(q.v.;* 10th century) and Ibn Sina (Avicenna [*q.v.*]; 10th–11th century) in the east and Ibn Rushd (Averroës [*q.v.*]; 12th century) in the west—constructed out-and-out rationalist systems of thought which came into conflict with certain dogmatic bases of Islam—the temporal creation of the world and the resurrection of the body, etc. Theologians rejected philosophy but were forced to support their dogmatic principles on some ground acceptable to reason. After al-Ghazzali's famous attack on philosophy, the latter lost vitality and in later development lived an impoverished life in liaison with speculative mysticism *(see* Ghazzali, al-). Significantly, al-Ghazzali's positive and voluminous work was entitled "The Revival of the Religious Sciences" *(Ihya' 'Ulumal-Din)* and not "The Revival of the Shari'a Sciences." He gave a definitely mystical emphasis to his influential interpretation of Islam. Thus, although his works won for Sufism a respectable place within the Islamic scheme, the inner dichotomy remained. This called forth, in the 14th century, a vigorous counterthesis emphasizing the *shari'a* (primarily in its newer sense of the term: external law) by Ibn Taimiya *(q.v.)*,

whose puritanical influence has been profound on modern Islam. In the 17th and 18th centuries some eminent men—Ahmad Sirhindi, 'Abd al-Ghani al-Nabulsi and Shah Waliy Allah of Delhi—made important attempts to reconstruct an "integral" Islam, on wider foundations.

Modern Islam.—These premodernist movements, arising entirely from an internal consciousness of religio-social and, in some cases, political degeneration, and culminating in the puritanical movement of Wahhabism (*see* WAHHABI), found a partial ally and partial opponent in the intellectual reformism of the modernists, who, after the middle of the 19th century, were also directly activated by western modern influences. The main points of agreement between the premodernist and modernist movements (between which there has been historical continuity) are a rejection of Sufism, a positive activist orientation and a stress on the unity of the Muslim community. With very rare exceptions, like that of Mohammed Iqbal (*q.v.*), there has been little deep-reaching philosophical rethinking of Islam such as may affect the basic religious issues. The main content of modernist reformism consists of sociopolitical reconstruction under the influence of western influence and criticism. On these issues, the early modernist work has been both reformist and apologetic—*i.e.*, designed to show that the modern western sociopolitical values are really identical with Islam as properly understood. Such problems as those of the status of women, of slavery and of political democracy were treated in this way. It was only in Turkey that a violent break with the past tradition occurred on the political-legal plane, although after 1950 a partial revision of the Turkish stand was in evidence. Elsewhere, the early modernists succeeded more in the apologetic direction than in the reformist, and a powerful reaction to early modernist reformism set in, generally speaking, after the second decade of the 20th century.

Primarily, the need was that of a psychological confidence vis-à-vis the west. However, with the gradual achievement of independence of the Muslim countries from European political hegemony, the concrete issues of sociopolitical construction and reform have confronted Muslims. Answers to such problems as those of the Islamic state and the status of the *shari'a* and the Tradition are pending. The relative inability to answer these questions stems from a lack of integration between the traditional learning and the modern secular educational centres, a problem to which the Muslim countries are beginning to address themselves.

At the educated middle-class, especially lower-middle-class, level, the results of the failure of early modernism and the onset of revivalism are blatantly evident. At this crucial point, which is the genuine point of entry to the as yet inert masses, new leaders, agitators and propagandists have taken over since the late 1920s and early '30s—people who have relentlessly and largely successfully exposed the weaknesses both of conservative Islam on the one hand and of the purely westernized sections (who are mainly at the helm) on the other. In actual practice, the newer leaders are more violently opposed to the latter than to the former, even though they themselves do not have any clearly worked out objectives. Such forces are the Jama'at-e-Islami in Pakistan and the Muslim Brotherhood (al-Ikhwan al-Muslimun) in Egypt. The latter was ruthlessly suppressed by the Egyptian regime in 1954 and the former was disbanded as a political organization by the military revolutionary government of Pakistan in 1958. It is clear, however, that neither measure, as it stands, can bridge the cleavage between the two wings and, in all probability, may even worsen the situation.

SECTS

The schools to which the various theological controversies gave rise did not express themselves in separatist sectarian organizations. The Mu'tazilites and the Qadarites were schools rather than sects. Sufism was a spiritual-social movement which, by and large, at least attempted to keep within the main body of Islam, called the Sunnis (*i.e.*, followers of the Prophet's way), even though the unorthodoxy of many Sufis on certain points is beyond doubt. The account given above, therefore, can be taken as the development of "central" Islam.

Kharijites.—Early in Islam, during the caliphate of the ill-fated 'Ali, two sects originated in Islam, which have remained to this day. When, after the battle of Siffin (657) between 'Ali and Mu'awiya over the succession to the caliphate (*q.v.*), the former submitted his claim to arbitration, a group from his supporters (called his Shi'a—*i.e.*, party) broke with him on the ground that "decision belongs to God alone" (Koran vi, 57) and not to human arbitrators. These were called the *Khawarij* (Kharijites). They taught that a perpetrator of a major sin no longer remained a believer and that faith consisted not only in belief but equally essentially in works. On the office of the caliphate, their view was that any Muslim, even a black slave, could fill it, provided he was otherwise qualified. They frequently rose in rebellion against the Omayyads and fought with remarkable if cruel heroism. But their power was slowly broken and only a few of them survive in north Africa and eastern Arabia. (*See* also KHARIJITES.)

Shi'ites.—The most important medieval sect, although numerically far smaller than the Sunnis (around 35,000,000), is that of the Shi'a, "the party of 'Ali." Their dissension was, in the first instance, political; they conceived of the caliph not as the executive chief of the community, as the Sunnis did, but as the infallible imam in whom worked a divine charisma restricted to the house of 'Ali. Politically, they came to represent the Persian reaction to the Arab ascendancy of the Omayyads. Theologically, they imported many Zoroastrian and Christian elements in their extreme subsectarian forms of Isma'ilism. The main body of the Shi'a is the "Twelvers" (Ithna 'Ashariya), who believe that the 12th and last imam, Mohammed al-Muntazar, disappeared in 878 but that he is still living and will appear before the last day to save the world. The Twelver Shi'a are found chiefly in Iran, Pakistan, Iraq and southern Lebanon. The Safavids established Twelver Shi'ism as the state creed of Persia in the 16th century and it has remained so.

The Shi'a have evolved their own system of law; they have their own canonized collection of the Tradition (Hadith). Some Shi'a have even believed that the text of the Koran, as it exists, is incomplete, that the part specifically devoted to the praise of 'Ali and his house has been expunged. To the creed, "There is no God but God and Mohammed is his apostle," they add "and 'Ali is his comrade [*waliy*, "chosen friend"]. An important doctrine is that of the *taqiya* or "hiding"; *i.e.*, the right of a Shi'ite to conceal his real beliefs in a hostile society without any risk of committing hypocrisy. As for practice, there are some modifications in the religious duties; the prescriptions of ritual purity (*tahara*) are given a prime importance. Pilgrimage to Mecca may be performed by a proxy or its place may be taken by a visit to the tombs of Shi'ite saints—of 'Ali at Najaf (Iraq), of Husain at Karbala (Iraq), of Rida (Riza) at Meshed (Iran) or of Fatima (daughter of the imam Musa) at Qom (Iran). Indeed, pilgrimages to the saints' tombs are a prominent characteristic of the Shi'a, although some Sufi practices in Sunni Islam come close to this. Public and collective prayers are not obligatory since there is no legitimate imam at present. The death of Husain (son of 'Ali) at Karbala is celebrated with meticulous care and vigour, accompanied by passion plays (*ta'zia; see* HASAN AND HUSAIN). Temporary marriage (*mut'a*), for a specified period—a year, a week or a day—is allowed and practised. (*See* also SHI'ISM.)

Under modern influences (*i.e.*, both modern thought and scholarship and political considerations of Muslim solidarity) there has grown an ecumenical sentiment between the Sunnis and the Shi'a with spasmodic actual efforts at *rapprochement*. This is further enhanced by the fact that, apart from Amir 'Ali, who rarely appears as a Shi'ite when he writes, the modern interpretations of Islam have been done mostly by Sunnis, who have influenced Shi'a writers.

Isma'ilis.—The Isma'ilis or the "Seveners" are the followers of Isma'il, whom they regard as the seventh imam, rather than his younger brother Musa (797) recognized by the "Twelvers." Their main body is led by the Aga Khan (*q.v.*), who is their spiritual and temporal head. Another branch, the Bohras, of India recognize their own separate leader. To the Isma'ilis belong also the Karmatians, the Fatimids of Egypt, the Assassins (the ancestors

of the main branch) and the Druze (*qq.v.; see* also ISMA'ILISM).

Zaidites.—The Zaidites, followers of Zaid, a grandson of Husain, are the nearest of the Shi'ites to the Sunni Islam. Although holding that the imamate belongs only to the descendants of 'Ali and Fatima (more than one of whom can be simultaneously imams), they accept Abu Bakr's and Omar's imamate as being justified by the circumstances. Their law also is close to that of the Hanafite Sunnis.

Ahmadiya.—In the modern period two important sects have arisen in Islam: Babism (*q.v.*), which, as the Baha'i Faith, has formally gone outside Islam, and the Ahmadiya, a sect founded by Mirza Ghulam Ahmad at the turn of the 20th century. He began by writing books against the Christian missionaries in defense of Islam but in 1879 began to claim that he was the promised Mahdi and the Messiah in the village of Qadian in the Punjab, India. Over against the general Muslim belief that Jesus was not actually crucified but was raised to heaven and will reappear on earth, Mirza Ghulam Ahmad claimed that Jesus, after escaping from crucifixion, went to Kashmir and died in Srinagar. He also claimed to be a manifestation (*buruz*) of Mohammed the Prophet and, for the Hindus, an incarnation of Krishna. Most probably he believed that he had come to unite all religions under Islam, and he positively disclaimed having any revealed book like the Koran or any new law; he accepted the Koran and the Islamic law. He reinterpreted the doctrine of *jihad* (*q.v.*) as being an exclusively pacific struggle "by the pen, not by the sword." In this doctrine and in that of the death of Jesus, he had been preceded by Sir Sayyid Ahmad Khan (*q.v.*), founder of the Aligarh Muslim college and of the modernist reform movement in India. In his claim to be a kind of prophet Mirza Ghulam Ahmad seems to have been directly inspired by the medieval Sufi Ibn 'Arabi. It is a common belief among the Indian Muslims that he was looked upon with favour by the British government.

The Ahmadiya sect, after the death of their first *khalifa* in 1912, split into two. The main body, called the Qadianis, recognized Mirza Bashir-ud-Din, a son of the founder, as the second *khalifa;* he proved himself a brilliant organizer. The smaller party, called the Lahore Ahmadiya, rejected the doctrine of Mirza Ghulam Ahmad's prophethood as well as his son as *khalifa* and moved closer to orthodoxy. Both parties have been very active missionaries of Islam especially in the west and in Africa. To would-be converts, the Qadianis do not present Islam as a specially sectarian affair but as the religion preached by the Prophet Mohammed; in Pakistan, however, where they have their headquarters, they declare as unbelievers all those Muslims who do not believe in Mirza Ghulam Ahmad. This led to serious riots and martial law in West Pakistan in 1953. Their number is very small.

MUSLIM INSTITUTIONS

Since Islam is a total way of life and admits of no division between religion and state, all its institutions are, in this sense, religious. Thus, the *zakat* tax, described above, is a socioeconomic measure enforced by the state, but it is also one of the prime religious duties.

The State.—The state itself is, indeed, a religious institution, having as its constitution and law the *shari'a—i.e.,* the religiomoral values of Islam. The form that the Islamic state assumed after the death of Mohammed is called the caliphate, with the caliph (*khalifa,* successor of Mohammed) at its head. The first caliph, Abu Bakr, was elected after a struggle between the Meccan Quraish (Kuraish, Quraysh, Koreish) and the Medina Ansar ("helpers"; *i.e.,* those who gave refuge to the Prophet and other Muslim emigrants from Mecca). Muslim orthodoxy, formulated later, held that the caliph must be from the Quraish. The caliph is neither a secular ruler nor the Muslim equivalent of the pope; he has the power neither to legislate nor to define dogma. He is the chief executive official of a religiously constituted community.

The caliph, theoretically, may be deposed if he proves incapable or violates some cardinal principle of Islam. In practice, however, there was no machinery either to declare a caliph unfit or to carry out the deposition. After the first four "rightly guided caliphs" (*al-khulafa' al-rashidun*), Mu'awiya introduced the hereditary principle, and the elective principle was reduced to a mere oath of obedience. The idealist *Khawarij* rose in rebellion against this several times, and in order to put an end to this internecine warfare orthodoxy was forced to adopt the principle that "an unjust ruler is to be tolerated rather than chaos" and that the peace and unity of the community may be broken at no cost. When, during the Abbasid period, the caliph gradually lost power and became a figurehead while the real power passed into the hands of the sultans (who recognized the caliphal authority only to the extent of reciting the Friday sermon, *khutba,* in his name and possibly using his name on the coins), the sultans exploited this very orthodox principle and elevated themselves as "the shadow of God" (*Zill Allah*) and "vicegerents of God." This change was helped undoubtedly by a revival of the Persian conception of the divine right of the king, so palpably embodied in the Fatimid theory of the caliphate.

The Ottoman caliphate arose out of a combination of this theory with the political extension of the Ottoman empire over the Muslim core lands, helped by the longevity of the dynasty. In the Ottomans, however, the sultanate and the caliphate remained two distinct powers, the one as a secular, the other as a religious function, and the caliphate never thereafter returned to its primal status. It was finally abolished in the 1920s by Mustafa Kemal Ataturk's regime, to the shock of the whole Islamic world, at the very moment when Indian Muslims were waging a fierce struggle against the British to restore the dismembered provinces of the Ottoman caliphate. Turkey established a secular state, claiming that this was sanctioned by Islam itself.

Ibn Taimiya, as early as the 13th century, had recognized that the world of Islam was no longer under one centre and probably could never be again. In modern times, although Islamic sentiment makes itself felt all over the Muslim world, the existence of different nationalisms in terms of separate political and cultural units is a fact. There are, however, innumerable Muslims who not only would like to see the Muslim world united but think that such union is achievable. Muslim modernists everywhere have been and are trying to establish genuinely Islamic states in modern democratic forms. This movement, for example, is largely responsible for the civil war that started in Indonesia in 1958. In Pakistan the political struggle for an Islamic state lasted from the country's birth in 1947 until 1956, when the constitution for an Islamic republic of Pakistan was adopted. This constitution was abrogated by the military revolution of 1958, and the problem of the status of Islam thereafter troubled officialdom in that country. Whatever decisions on this question the various Muslim countries may take, they cannot fail to affect both the future of Islam itself and the world at large.

Administration.—As for the techniques and the machinery of administration, the Muslims started very early to adapt these from the Persian and Byzantine systems of government. Thus, the second caliph, Omar, on the advice of the Persian prince Hurmuz, established a *diwan* to maintain records for the distribution of stipends to soldiers (*see* DIWAN). The Omayyads struck coins for the first time in the history of Islam. And as the task of administration became much more complicated, several *diwans* or *bureaux* were established for the purpose of collecting taxes and administering the law. The first Abbasid caliph, Abu'l-Abbas, appointed a vizier (*wazir,* a confidential administrator). Gradually a secretarial class arose, by and large Persian in origin, which became a powerful factor not only in state policies but also in influencing sociopolitical movements. The most important of these in the Abbasid period, the Shu'ubiya movement, was supported by the professional secretarial classes and directed against Arab hegemony. At times when a sultan became very powerful, he would take the place of the vizier under the title Amir-al-Umara'. The most celebrated viziers are the Barmecides (*q.v.*) of the Abbasid Harun al-Rashid and Nizam al-Mulk (*see* NIZAM AL-MULK) of the Seljuk sultan Alp Arslan.

The main tasks of the administration were (1) to collect and distribute revenues, (2) to administer law and (3) to perform

jihad or holy war. The taxes collected were the *zakat* from the Muslims, the poll tax (*jizya*) from non-Muslims and the land tax and the professional earnings tax (*kharaj*). For *jihad*—which came to mean not only war operations against non-Muslim states but also the suppression of lawlessness within—an army was kept and paid from *zakat* funds. In the beginning all able-bodied adult males were conscripted "in the path of God" and in Omar's time were paid regular stipends. These forces were kept as occupation forces in the conquered lands. But later paid soldiers were used. External *jihad* was strictly regulated by law (*see* JIHAD).

To keep a check on public morality, the office of the moral police or *muhtasib* was instituted. The *muhtasibs'* function was preventive; they tried to see to it that mischief did not occur. After the moral breach took place it was the qadi, often second in importance only to the head of state, who decided the case in court. The qadi interacted with another important officer, the mufti (*q.v.*), the authoritative interpreter of the law and, from this point of view, ranking religiously higher than the qadi, who was a purely judicial official. The qadi, as a judge, did not merely accept the statement of the mufti; in each individual case before him he exercised judicial interpretation himself and thus, in course of time, Muslim case law was built up and compiled in the several compendia of *fiqh*. The qadi also administered the religious endowments (*awqaf*) which became an important part of state administration. These charitable legacies were the main support (besides gifts from rulers and princes) of schools, mosques, various social-service institutions and the numerous Sufi organizations.

Education.—Education has occupied an important place in Muslim life, and the Hadith, supported by the Koran, set high value on knowledge and learning—*e.g.*, "seek knowledge even though it be in China." In the actual development of the educational system, however, a sharp division existed between primary and higher education (A. S. Tritton, *Materials on Muslim Education in the Middle Ages*, 1957), with the effect that there was no standardized and systematic feeding of the higher level by the lower. There is ample evidence of school education in existence in the first century of Islam. The ruthless but remarkable Omayyad governor of Iraq al-Hajjaj ibn Yusuf is reported to have been a schoolmaster after the profession of his father. Instruction included the inculcation of honesty, truthfulness and moral character in general. The subjects taught—at a rudimentary level—were reading and writing, the Koran, prayer, catechism, some law and arithmetic. Sometimes nonacademic training (*e.g.*, in swimming and archery) was also given, but practically no attention was paid to technical training. This latter was given, in medieval Islam, by the guilds (which became a very powerful institution, both socially and spiritually, for example, in Turkey), which provided training in arts and crafts through their apprentice system. In later medieval Islam, the establishment of a network of Sufi orders throughout the Muslim world resulted in Sufi training centres (*zawiyas*, *tekyes* and *khanqahs*) where spiritual training was often combined with academic instruction; in some even military training was given to effect *jihad* (*see* MARABOUT). There is a considerable literature on the theory of education, on the behaviour of the student and teacher vis-à-vis each other, even on the role of the parents.

But the pride of Islam was its university system, which produced the class of the *'ulama'* (ulema; *q.v.*) or learned men, the religious leaders of Islam. From this class were drawn the imams, the qadis and the muftis (and other high state-religious officials like the *Shaikh al-Islam*). The *'ulama'* were a very powerful class and at times decisively influenced important policies of even later sultans both in Turkey and in India. In modern times they have gradually lost much ground vis-à-vis the western educated classes, and in Turkey they were altogether abolished; elsewhere, however, their hold on the vast body of the conservative masses remains unshaken. One of the most crucial problems before modern Muslims is the creation of a new body of *'ulama'* capable of integrating tradition with modernity. For so far, in modern Islam, an almost complete cleavage has existed between the *'ulama'*, who know only the tradition, and the modern laity, which has been educated in and knows only modern secular subjects. The modernist religious thinkers (who have been isolated and have never constituted a school of thought) have not been able to bridge the gap. There are, however, incipient developments in various parts of the Muslim world (the first took place in the Ankara university of Turkey) to integrate the two educational systems.

As early as the first century of Islam a hall (*majlis*) for the teaching of tradition is mentioned—indeed, Muslim education began with the tradition, and "knowledge" (*'ilm*) meant for the early Muslims a knowledge of what the tradition (especially the prophetic tradition) had to say on all matters. Gradually, colleges and halls grew which catered only for religious education. In 830 the caliph Ma'mun established in Baghdad a research academy for philosophy and astronomy, etc.; the Fatimids established a similar institution in Cairo in the 12th century. For the rest, secular sciences such as philosophy, astronomy and medicine were cultivated and pursued only by certain outstanding individuals to whom princes and rulers extended patronage, providing funds and facilities. Hospitals developed, where much clinical work was done. Islamic philosophical and medical works had a deep and enduring influence on the European tradition through Latin translations made in Spain and Sicily. Princes vied with one another in gathering around themselves, besides poets, men of learning, and often built enormous libraries which they were permitted to use. But the whole phenomenon remained individual.

It was characteristic of students throughout medieval Islam to travel from one place to another, from one master (*shaikh*) to another, in search of knowledge. This was much more important in early Islam than sedentary education at a single institution, and students obtained from each master a certificate (*ijaza*) to teach either a book or a subject (or subjects) learned from him. Certain famous colleges, however, sprang up in Baghdad, Nishapur, Damascus, Cairo and many other centres throughout the Muslim world. The most celebrated of the relatively early colleges was the Nizamiya, founded in Baghdad by the famous Seljuk vizier Nizam al-Mulk in 1067. Built, in the first instance, to teach Shafi'i law, it soon added theology and tradition; the great al-Ghazzali was on its staff. More stately and sumptuous and far wealthier in endowment was the Mustansiriya at Baghdad, founded in 1234 with a large staff to teach the four schools of law, as well as other disciplines. The Azhar in Cairo, the most important representative of the medieval schools still in existence (although it now teaches some modern subjects as well), was completed as a mosque in 977 and 16 years later started functioning as a seat of learning. In the latter half of the medieval period, philosophy (and medicine) were also included in the syllabi, although original independent philosophy was suspect and discouraged and its level consequently degenerated. Indeed, philosophy was later completely thrown out of the Azhar and was only reintroduced through the efforts of Jamal al-Din al-Afghani toward the end of the 19th century.

The Arts.—From the description given above of the salient and central specifically Islamic institutions, it is clear that the influence of Islam has been pervasive in the lives of its followers. This must not, however, make the reader oblivious of the fact that in its administrative techniques and its institutions, in its law, generally in its developed thought and, indeed, in its art it borrowed heavily from the cultures it encountered in the new lands to which it spread with such astonishing rapidity. Its early administrative system, including monetary and postal systems, was altogether indebted to the Persian and Byzantine empires. But whatever Islam borrowed, it impressed its own unmistakable stamp upon it. Similarly, the over-riding principle under which Islamic art developed—under all the foreign influences—was the religious rejection of images, and, in general, of representative forms of art. The arabesque, so characteristic of Islamic art, may be said to represent nothing particular, and this negative aspect has been emphasized by modern critics; but it can be more positively said to remind one of the absoluteness, transcendence and unity of God. (*See* ISLAMIC ART.)

But Islamic art expressed itself, for the most part, in architecture, especially in mosque architecture. In Islamic architecture, indeed, may be seen both the centrality of Islam and its tendency to acquire diverse elements from different local cultures. Among the earliest monuments is the well-known Dome of the Rock

(691; not, however, a mosque but a memorial) in Jerusalem, the Mosque of 'Amr in old Cairo and the mosque of Kairouan, Tunisia (7th century). The early Syro-Egyptian type of mosque is a heavily columned construction with a pulpit (*minbar*) for the preaching of sermons and a niche (*mihrab*) oriented toward the Ka'ba sanctuary (which is not a mosque but "the House of God"; *i.e.*, the focal point of the divine contact with the earth). In north African and Spanish Muslim architecture, Syro-Egyptian elements are fused with Roman-Byzantine characteristics. In the famous Persian mosques, the specifically Iranian elements are apparent—the tapered brick pillars, the arches, each supported by several pillars, the huge arcades and the four sides, called *iwans* (an unmistakable reference to the palaces of the Khosraus). Turkey developed its cupola-domed mosques and its characteristic form of the college building (the *madrasa*) with four wings for the teaching of the four schools of Islamic law, converging in an unroofed centre. Early Muslim architecture in India is, in its interior—discounting the façade—hardly distinguishable from Hindu buildings, but after the Moguls Islamo-Persian supplanted native Indian elements. (*See* Islamic Architecture.)

Instrumental music was forbidden by Islamic orthodoxy, although the use of drums was allowed on special festive occasions such as marriage. Nevertheless, music, both vocal and instrumental was cultivated, especially at the courts of the caliphs and princes and later by the Sufi orders, which sought to legalize it under the name of *sima'* for the purpose of inducing the mystical state of trance (opposed no doubt by the orthodox). Greek music influenced Arab music and the philosopher al-Farabi is accredited with having constructed a well-known stringed instrument called the *qanun*. (*See* also Oriental Music.)

Drama was forbidden since it fell within the domain of representational art. Story literature was tolerated, and famous Indian storybooks—the *Thousand and One Nights* and the *Kalila wa Dimna*—were translated from the Persian, introducing secular prose into Islam. Didactic and especially pious stories were invented and widely used by the common traveling preachers even though the didactic stories too were religiously suspect. Pure fiction (*e.g.*, in the form of novels) for the purpose of entertainment was interdicted.

Besides architecture, the only form of fine art that flourished unhindered was poetry (even though not completely beyond suspicion because of the koranic saying "Poets are leaders of the errant ones: they stray about in every valley . . . except those who believe . . ."; xxvi, 224), a form of expression pre-eminently characteristic of the east. The Arab genius is almost natively poetical, with a strong and vivid imagination unshackled by the logical system and order that reason imposes upon the mind. Consequently, the favourite type of poetry was the lyric (*ghazal*) and the eulogy (*qasida*), wherein each verse is an autonomous unit with no logical dependence on the preceding or the succeeding verses and, as a pithy and succinct expression of a state of feeling, eminently capable of being used as a maxim. Nature poetry was absent, and the first epic work (the *Shah-Nama* of Firdausi) was only a Persian reaction against the Arab mind—spiritually and politically. This it is which renders intelligible the fact that the Muslims, who understood and developed Greek science and philosophy, failed completely to understand Aristotle's work on the poetic art. In the later centuries, poetry was used as a fascinating and powerful vehicle for communicating the spiritual message of the Sufis. (*See* also Arabic Literature.)

MUSLIM SOCIETY

From the time of origin of Islam, social reform, through the enunciation of moral principles and actual legal enactments, formed part of the central core of Islamic teaching. Islam, indeed, may be described as a socioeconomic reform movement backed by certain strong religio-ethical ideas about God, man and the universe. In Medina, as soon as conditions permitted him to do so, the Prophet set up a community-state with a constitution; and, as situations demanded, necessary legislation was supplied to it in the form of either koranic ordinances or the Prophet's commands, which usually were not issued without consulting senior members of the community. After the Prophet's death, when within a few decades Islam expanded into a gigantic empire, a whole complex of legal, social and administrative developments took place with astonishing rapidity.

Koranic Social Laws.—On the social side Islam laid a firm moral basis for a total, purposeful community. The intention of its initial legislation was to improve and reform the already existing customary law of the Arabs, which was in many respects left intact. The koranic reforms had particular reference to remedying certain serious economic and social ills. In economics the principle adopted was that wealth "should not be allowed to circulate among the rich only" (Koran lix, 7). Consequently, usury and other forms of exorbitant economic exploitation were severely forbidden; the *zakat* tax on wealth (*see* above) was imposed and helping the poor and the needy was insisted on. The drinking of alcohol was at first restricted, then totally prohibited; so was gambling. Emancipation of slaves was exalted as a cardinal virtue, and a general, quasi-legal injunction was given to allow slaves to purchase their freedom through a contract (*mukataba*). A rigorously moral state of affairs was sought in family life and relations between the sexes. The Koran ordains "a hundred lashes for the adulterer and the adultress," although tradition restricts this punishment to unmarried persons and for married people prescribes death by stoning (indicating the influence of Jewish law already existing in Medina; *cf.* Deut. xx, 22–23).

The most far-reaching reforms were introduced in laws of marriage. Of the different forms of marriage existing in pagan Arabia, Islam banned all that were morally questionable and restricted the number of wives to four. Legally, reform could go no further in that state of social organization, and the Koran had to content itself with moral enunciations to the effect that if a man could not do justice among wives, then he must take only one wife. The Koran sought to improve the lot of women by legislating for specific women's rights. It lays down a general principle that the rights of women against men must be commensurate with the latter's rights over women, adding, "But men are a degree higher." These words must be interpreted in the light of the actual social situation, in which man was not only the breadwinner but the essential operative factor. It is in the light of this situation, again, that the koranic injunctions should be understood to the effect that the evidence of one man equals that of two women because, "should one of them slip, the other may correct her" (ii, 282). In the matter of inheritance, daughters were allowed only half the shares given to sons. (*See* also Harem.)

In regard to food, the Koran emphatically starts with the principle that all "good" things must be allowed and then forbids four items: corpse, blood, meat of swine and of those animals slaughtered as offerings to others than God. The last prohibition is a direct consequence of the koranic monotheism and the third shows the obvious influence of Judaism. But the Koran categorically allows food of the "people of the book"—*i.e.*, Christians and Jews.

Egalitarianism and Aristocracy.—The most fundamental and dynamic factor of social ethic that Islam gave was egalitarianism: all members of the faith, irrespective of race, colour or social or economic status, are equal participants in the community. One great result of this outlook has been the very special concern of the community—in contrast to Christianity—to avoid the creation of a clerical institution. This does not mean that there did not arise in Islam a class of *'ulama'* (*see* above) who supplied religious leadership and offered expert interpretations of Islam. But these men had no title to a vicarage of God; they obtained recognition only on the basis of their individual attainments and only to the extent that they could exert intellectual and moral influence. A far-reaching consequence of this phenomenon was that, within the terms of the actual social legislation provided by the Koran—which has remained valid both in theory and practice up to the present—a tremendous diversity of cultural patterns and social behaviour was absorbed and islamized. Already in the early schools of law, "good custom" (*'urf*) was recognized as a source of law. This diversity was canonized a little later by an alleged tradition of the Prophet: "Differences among my community are a mercy of God."

Some of the most important social developments popularly as-

sociated with Islam by non-Muslims, but in some cases also by Muslims themselves, originate from the impact of different cultures on early Islamic society. A striking instance is afforded by the institution of the veil or purdah among the Muslims, which in both Muslim and non-Muslim eyes is a concomitant of Islam. All the Koran had enjoined was a sense of modesty, in contrast to pre-Islamic Arabian sex morality, and that women "should not make an exhibition of their beauty" (xxiv, 31); the Prophet's wives were ordered a more strict seclusion. As the Arabs settled outside Arabia, however, they were influenced by certain aristocratic habits of their conquered subjects in the neighbouring empires. To this period of acculturation and ensuing moral laxity must also belong that large body of traditions wherein the Prophet had allegedly warned against general moral and especially female corruption on the eve of Doomsday. Indeed, roughly in this period and in this milieu originates the bulk of that teaching which later came to constitute much of the warp and woof of Muslim social ethics—fatalism, Messianism, indifference to public affairs and a political docility and conformism. And yet it was from this very milieu that the idea of the community was confirmed and reinvigorated.

Certain other important developments of this type assumed a fairly general character throughout medieval Islamic society. The Arabs, when they first settled in Iraq and Egypt, were discouraged from doing especially manual work and agriculture; the purpose was to keep them as soldiers. Gradually they developed into the new aristocratic class while their non-Arab clients (*mawali*, "freed slaves") performed manual labour and especially agriculture. From this arose the myth that the Prophet had discouraged agricultural occupation. That this could not have been the case is obvious from the fact that the Medinese population was largely agricultural. Against this the non-Arab clients—who now claimed to be better Muslims than the Arabs themselves—exalted manual labour and put into circulation traditions which alleged that the Prophet himself had done all kinds of manual work. But the aristocratic tradition, when it reached other and new Muslim lands, was accidentally reinvigorated by certain local factors. In India, for example, where social stratification had already existed, where the conquering Muslim minority had to remain as an administrative and military aristocracy and where largely the local menial classes were converted, the social stratification was further intensified and, further, the Muslims were unable to develop a strong commercial class. In Ottoman Turkey "Turk" became more or less a term of contempt for the Turkish peasant as distinguished from a gentleman of the town.

Almost exactly parallel with this distinction ran another very important one which was connected with Islam as a specifically religious phenomenon: the Islamic educational institutions which turned out *'ulama'* and were also controlled by *'ulama'*—who were largely responsible for the creation and maintenance of Muslim intellectual culture—were all confined to urban life. Some modern scholars have, indeed, suggested that Islam is essentially an urban culture. Whether or not this is true, certainly during the middle ages of Islam (*i.e.*, up to at least the 18th century), by a conglomeration of causes, orthodox Islam remained confined largely to the cities. As a result, the unifying forces of Islamic culture hardly penetrated the countryside, which in each region presented a variety of beliefs and practices sometimes not even remotely connected with Islam.

Diversity in Local Practice.—When from the 12th century onward the Sufi movement spread rapidly, it took on the form of a tremendous thrust of popular religion against the orthodoxy represented by the *'ulama'*. Its almost uncontrolled latitudinarianism encompassed the various local practices and attitudes, whether compatible or incompatible with Islam. The *'ulama'* continued to exert steady pressure but could not make much headway until the tide of popular religion began to abate during the 18th and especially the 19th century. From the animistic practices of the African tribes, through the shamanistic rituals of the central Asians, to the Indian mystery-mongering cults—all had Sufi support. Under these conditions, the half-islamized and the nominally islamized groups, even though they still enjoyed a sense of solidarity with the community, could not be really and fully islamized when the influence of the modern west came to be felt in Muslim lands. In India, the custom of sati, by which widows burned themselves alive along with their deceased husbands (*see* SUTTEE), persisted among certain converted groups until the late Mogul period, as did a host of other pre-Islamic survivals. Both Hindus and Muslims continue to venerate certain shrines, and, indeed, until the 20th century there were pockets of illiterate "Muslims" in India among whom even the names remained Hindu. A definite continuation of Hinduism in Indian Islam has been the extreme dislike of widows to remarry. The large-scale disinheritance of women, in opposition to the provisions of the *shari'a*, is also due to local influences, although now the *shari'a* law has been officially reinstated in this respect. The tenacity and persistence of certain "national" customs and habits among the Turks is well-known, although the initiation rite of the Bektashi dervishes, using wine, bread and cheese in a clear survival from Christianity, may be an extreme example.

Indonesia affords a striking example of this phenomenon. Due perhaps to the late conversion of that region, Islamic social ethic and code have made headway only in matters of marital status; otherwise it is submerged under what is called *'adat*, or custom. Not only are several tribes still matriarchal, but, according to the generally prevailing *adat* law, even the *shari'a* marriage is not considered valid until it is followed by another ceremony surviving from pre-Islamic tradition. Culturally, many Indonesians still retain either the old Hindu or pagan traditions: for example, the Hindu epic Mahabharata is cherished as a literary and even quasi-religious work. In the archipelago also one meets with the sharpest division between the *shari'a* and the Sufi way: in the same home the wife may be found offering the obligatory ritual prayers of Islam, while the husband abstains from this paramount religious duty on the ground that, though his wife belongs to the *shari'a* ("religious law"), he himself adheres to the *tariqat* (the Sufi way). Since the 19th century, however, there has been a renascence of orthodox Islam in Indonesia because of fresh contacts with the middle east, and *'ulama'* groups have arisen exerting pressure for reforms and for the conformity of social practices and institutions to the norms of Islam.

Reform Movements.—Since the 18th century, indeed, there has been a general upsurge of reform in almost the entire world of Islam. Various more or less indigenous movements, harbingers of renascence, arose in different regions, the forerunner of all being the Wahhabi movement in Arabia (*see* WAHHABI). A fundamental characteristic of all these movements has been emphasis on the social content of Islam rather than on the purely spiritual side or eschatological doctrines that characterized medieval Islam. This is because the reformers saw degeneration in Islam as a society and not as a religious system. Their general aim, therefore, was to free the community from foreign accretions and un-Islamic influences and to return to the simple practice of the early community. It is this preoccupation with society that causes even the Sufi *tariqats* that arose in the 19th century to look more like social organizations than fraternities of spiritual adepts. This is true also of the newer African Sufi orders, especially the Senusis. The emphasis on society is remarkably illustrated by a letter from Sheikh as- Sanusi to a tribe, telling them that if the people simply cultivated truthfulness and carried out certain measures of social and economic justice they would be blissful. One great result of this new attention to the social side was a recession in the tide of Sufism as a purely spiritual discipline.

But these reforms, although important in themselves, were not enough: they were rather forerunners of the modernist reform programs. Their main contribution was to insist on *ijtihad* (*see* above, *Development of the Shari'a*), and thereby to liberate the minds from the shackles of the medieval schools; but, by insisting on a simple "return" to the early past in order to imitate it literally and re-create it, they often brought about a form of reaction which was bound to prove even more difficult to shake off than the conservatism of the medieval schools. The liberal modernist, in his social thinking, had, therefore, to take a further leap and enunciate the principle of a reinterpretation of Islam in the light of new situations. The main line of this reinterpretative activity has concen-

trated on the social institutions of family and slavery. The first task of the modernist was to emphasize the reform activity of the Prophet and the great improvement he made in these fields on the then *status quo*. This done, the modernist was ready to underline the spirit of Islamic legislation for modern society. This activity gave rise to much apologetic literature, as was inevitable.

On the question of polygamy, the modernists contended that the Koran had, to begin with, limited the maximum number of wives to four. But the Koran had also morally enjoined the Muslim to resort to polygamy only if he could do justice among different wives, which, it says, is impossible. By putting these two injunctions together, the modernist argument stated, we reach the conclusion that the Koran sanctioned restricted polygamy only for that society and that its real intention was to ban polygamy when conditions changed. The modernists argued on similar lines in the parallel case of slavery: a temporary legal sanction in view of then-existing conditions, but really a total ban. This argument is plausible, but one must conclude on its basis that the Muslim community subsequently failed to realize the intentions of the Koran—a conclusion which a conservative would most certainly reject. Thus modernism and conservatism came into acute conflict.

Slavery is not a real problem, and even in Saudi Arabia it has been banned, although not without the moral pressure of international opinion, mainly expressed through the United Nations. Polygamy has been either banned or severely restricted in many Muslim countries, although only in Turkey has the ban been imposed in complete disregard of the *shari'a* and on a purely secular basis. Other countries—Tunisia, Morocco, Syria, Lebanon, Pakistan and Iraq—have resorted to legislation through interpretation of the *shari'a*. While a law like that of Tunisia virtually amounts to a total ban on polygamy, other enactments, such as that of Pakistan, seek merely to restrict it sharply. There is little doubt that other Muslim countries will pass similar measures. But it is one thing to enact laws and quite another to make them effective or accepted. Indeed, even in Turkey, which prohibited polygamy as early as 1926, and where reforms are making steady headway, polygamy and unregulated "private" marriages still persist in large numbers.

It is social forces—the confrontation of the sexes in educational and vocational institutions, the steadily increasing economic independence of women, etc.—and not legal enactments that are changing the situation of polygamy, although, of course, legislation is helpful and necessary. But the forces of conservatism remain very powerful and must be expected to erupt from time to time even if they cannot actually reverse the process of modernization. With the passage of time, a modern innovation becomes good and settled tradition. The *'ulama'* resisted the education of girls; now, with widespread coeducation, education of girls seems good, conservative tradition. But in the transition period (as in the west) imbalances are bound to occur in Muslim societies. For example (though exact statistics are not available), the number of divorces and divorce cases in Malaya represent an astonishingly high percentage of marriages; though the high number of divorces actually granted may be a result of the particular judicial system connected with divorce, the really amazing phenomenon is the number of divorces sought, and this must be directly connected with the growing economic independence of women. On other social matters, such as that of inheritance, fresh thinking is going on and will certainly result in certain modifications.

ISLAMIC ARCHITECTURE. Islamic architecture may be defined as the architecture of the peoples who have embraced the Islamic faith. The term Arab should never be used in this connection for it is completely misleading. The conquering Arabs, when they did begin to have architectural ambitions, employed the local people and drew upon their technical skill and architectural traditions.

THE FIRST THREE CENTURIES

In the time of Mohammed the Arabs had nothing worthy of the name of architecture. Only a small part of the population was settled and these lived in dwellings which were scarcely more than hovels.

When the hostility of the people of Mecca had caused Mohammed to migrate to Medina in A.D. 622, he built a house for himself consisting of a mud-brick enclosure about 50 yd. square. Against the outer side of the east wall were *hujra* ("small huts") for his wives. There is a description of them by an eyewitness who saw them just before they were demolished by order of the caliph al-Walid I in 707: "There were four houses of mud brick, with rooms partitioned by palm branches, and five made of palm branches plastered with mud and not subdivided. Over the doors were curtains of black haircloth. One could reach the roof with the hand" (Ibn Sa'd, *Kitab al-Tabaqat al-Kabir*). The courtyard, which afterward served as a place of prayer, was at first open, but, as the Companions complained of being exposed to the burning heat of the sun, a shelter was erected, consisting of palm trunks used as columns supporting a roof of palm leaves and mud. Such was the house of the leader of the community at Medina. Nor did Mohammed wish to alter these conditions; he was entirely without architectural ambitions, and Ibn Sa'd quotes him as follows: "The most unprofitable thing that eateth up the wealth of a Believer is building."

The men who formed the armies of the conquest were mainly Bedouin, but even those who came from permanent settlements, such as Mecca and Medina, knew nothing of art and architecture. Their advance was fanwise: those who advanced northward entered territory which had been under Hellenistic influence for 1,000 years, and those who advanced northeast entered territory which had been under Persian influence for even longer. And not only the cultural but also the material conditions were different. Syria was a country of excellent building materials. Syrian limestone was the best of its kind and cedar wood was plentiful, for the Lebanon had not yet been deforested. So those who invaded Syria found themselves in a country of splendid buildings—churches of cut stone, with arcades on marble columns and gable roofs of cedar, and with large surfaces covered with coloured glass mosaic on a glistening gold background. On the other hand, those who invaded Mesopotamia and Persia met with buildings of brick, sometimes of mud brick, sometimes vaulted but more often with flat roofs of palm trunks, palm leaves and mud. Hence the duality observed in early Muslim architecture.

In these early days the invaders, when they conquered a town in Syria, usually took one of the churches and converted it, a very simple matter, for the *qibla* (direction of Mecca) being due south and the churches being turned toward the east, it was only necessary to close the western entrances, make fresh ones in the north side and pray across the aisles. That this is exactly what happened can be verified in the Great Mosque of Hama, where the west front of the Kanisat al-Uzma ("Great church"), which was converted into a mosque in 637, forms the west side of the sanctuary.

But the situation was different in Iraq, for there the Arabs founded new towns, so pre-existing buildings could not be em-

ployed. At Basra, founded *c.* 635, the first mosque was simply a rectangle marked out on the ground. According to another account it was enclosed by a fence of reeds. At Kufa, founded in 638, an area about 100 yd. square was enclosed not by walls but by a ditch only, the sole architectural feature being a shelter on columns (taken from the ruins of Hira) which ran along the south-west side of the mosque.

The first mosque in Egypt, the Mosque of 'Amr built in 641–642, was equally primitive. It measured 50 × 30 cubits (about 80 × 50 ft.) and had six doors and a low roof, probably of palm trunks resting on palm-trunk columns.

The first mosques worthy of the name of architecture were the second Great Mosques at Basra (665) and Kufa (670). The latter was built by a man "who had been one of the builders of Khosrau," and he designed the mosque with five rows of columns on the *qibla* side and two rows only on the other three sides. The columns, which were very tall, were not surmounted by arches, and it is obvious that the sanctuary must have looked like an apadana, or hall of columns, of the ancient Persian kings.

The oldest existing Muslim monument is the Dome of the Rock at Jerusalem, built by the caliph Abd-al-Malik and finished in 691. It is a concentric annular structure consisting of a wooden dome 20.44 m. in diameter, set on a high drum and pierced with 16 windows. The dome rests on 4 piers and 12 columns which are placed in a circle and so arranged that 3 columns alternate with each pier. This circle of supports is placed in the centre of a large octagon averaging 20.60 m. a side, formed by eight walls 9½ m. high (excluding the parapet which adds 2.60 m.), each pierced in its upper half by five windows. Between the outer octagon and the inner circle is an intermediate octagonal arcade, the arches being borne by 8 piers and 16 columns. It is not a mosque but a *mashhad* ("shrine"), built over the sacred rock that is regarded as the omphalos (navel) of the world. The decoration is of the most splendid kind. The exterior was originally covered to half its height by marble paneling, and from there upward with glass mosaic on a glistening gold background. Internally all the arcades were likewise decorated with mosaic and the walls with quartered marble paneling; *i.e.*, each slab was cut in half and opened like a book, the result being that the veining ran toward the joint. The process is then repeated so that four slabs make a unit. Although this is the most beautiful way of using marble for paneling, it does not appear to have been employed after 750.

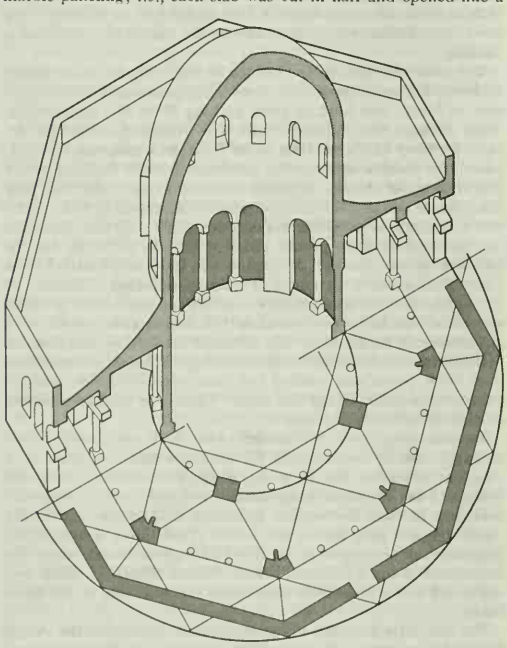

FIG. 1.—THE DOME OF THE ROCK, JERUSALEM

About 20 years after the completion of the Dome of the Rock, al-Walid (A.D. 705–715) built the Aqsa mosque (al-Masjid al-Aqsa) at Jerusalem and the Great Mosque at Damascus. In the former (which is not a conversion of a church built under Justinian I, as is often erroneously stated, for Justinian's church stood elsewhere and lasted until after 800), the arcades ran at right angles to the *qibla* wall, in the latter parallel to it. The arcades in both cases were built in two tiers in order to obtain a great height of ceiling with comparatively short columns taken from other buildings, a system adopted later at Córdoba, Spain. At Damascus the mosque was built in what had been the temenos, or sacred enclosure, of a pagan temple, measuring about 156 m. from east to west and 100 m. from north to south. Three arcades, cut through their centre by a transept, were built parallel to the south wall and a single arcade round the other three sides. Of the four axial entrances of the temenos, three were preserved in the mosque, the fourth being blocked up by the mihrab (prayer niche indicating the direction of Mecca). Here again the same splendid decoration in marble and mosaic was employed as in the Dome of the Rock at Jerusalem. At the four corners of the ancient temenos were four square towers; these became the first minarets in Islam. (At Medina, where there was no minaret until al-Walid's time, the call to prayer was made from the roof of a neighbouring house.) Ibn al-Faqih (903) says: "The minarets which are in the Damascus mosque were originally watchtowers in the Greek days. . . ." And al-Masudi says: "Then came Christianity and it (the temenos) became a church; then came Islam and it became a mosque and the four *sawami* (*i.e.*, the four corner towers) were not changed; they serve for the call to prayer at the present day."

The Omayyad caliphs were great builders of palaces, many of which have a fortified appearance externally. This is to be explained by the route taken by the armies of the conquest. They passed a long line of Roman frontier forts which ran from the Gulf of Aqaba to Damascus and beyond. Having been in the habit of occupying forts, the Omayyads apparently came to look upon a rectangular enclosure flanked by towers as a necessary feature of a princely residence. Their palaces were richly decorated with marble paneling and mosaics; *e.g.*, al-Walid's palace at Minya on the Sea of Tiberias (Sea of Galilee), Hisham's palace at Mefjir (4 mi. N. of Jericho). Some, like the one at Qasr 'Amrah, were even decorated with fresco paintings of human figures, for the prohibition against figural representation did not become formal until *c.* 800.

The fall of the Omayyad dynasty in 750 and the transfer of the capital of the caliphate from Damascus to Baghdad by the Abbasid caliph al-Mansur was as far-reaching in its effect as the transfer of the capital of the Roman empire from Rome to Constantinople. Hitherto the Islamic capital had been in territory which, since the time of Alexander III, had been in the sphere of Hellenistic culture. This was replaced by the cultural influences of Sasanian Persia, to which sphere Iraq belonged. This made itself felt in the design of the new capital, Baghdad, which was given a circular form like the Parthian capital Ctesiphon, Darab and Firuzabad. A mosque 100 m. square with wooden columns supporting a flat roof was built in the centre of the city, and the caliph's palace, 200 m. square, was built in contact with its *qibla* side, so that the caliph could go directly from his palace into the *maqsura* of the mosque, a screened-off area which included the mihrab and the pulpit. This was the scheme first adopted at Damascus and then at Basra, Kufa, Wasit, Merv and other places. About this time was built the earliest example of a building entirely constructed with free-standing, pointed-arched arcades of 38 arches supporting tunnel vaults: the Cistern of Er Ramle, the only Abbasid monument in Palestine, dated 172 A.H. (A.D. 789) by an inscription of Harun al-Rashid.

In 827 Abdallah ibn Tahir, the Abbasid governor of Egypt, doubled the size of the Mosque of 'Amr (at Al Fustat) by the addition to the west of its exact area in the same shape. It follows

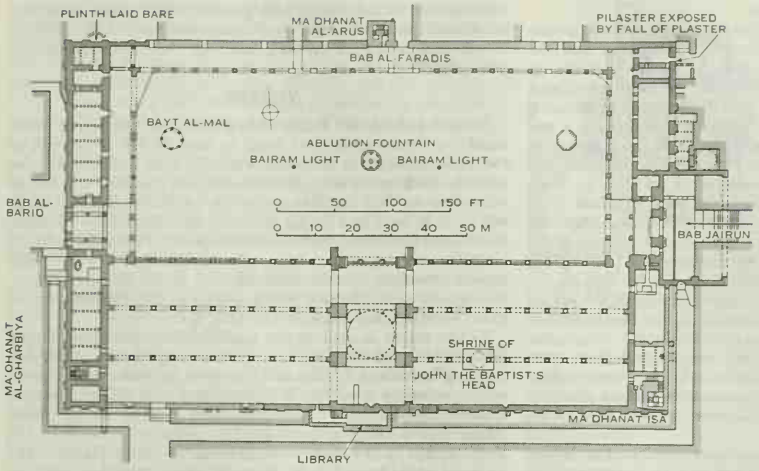

FIG. 2.—PLAN OF THE GREAT MOSQUE, DAMASCUS

that no part of the present structure lying to the right of a line drawn through its centre can possibly be older than 827. It then measured about 109 × 120 m., as does the present building. It is known (from excavations) that there were seven arcades on the southeast and northwest sides and four on the southwest side. On the northeast the arcades ran perpendicular to the court. The only decoration that has survived is that carved on the wooden friezes and the tie beams of a few windows. It consists of late acanthus ornament, derived from the Hellenistic art of Syria, and shows that the Abbasid art of Iraq, which is found 50 years later in the Mosque of Ibn Tulun, had not yet reached Egypt.

Like the Mosque of 'Amr, the Great Mosque of Kairouan was founded in the early days of Islam, but no part of the present structure (except the minaret) is earlier than the 9th century, for the whole mosque was rebuilt by the Aghlabid Ziyadatallah I in 836. The sanctuary consists of 16 arcades of 7 arches, each running at right angles to the *qibla* wall but without reaching it, for a transverse arcade runs at a distance of 6 m. from it, and it is against this arcade that the 16 arcades stop. The side aisles are about 3.30 m. in width as against 5.40 m. for the central aisle, which must have measured 6.60 m. before its width was reduced by two arcades built in contact with it, without any bond or liaison of any sort. This modification was the work of Ibrahim II in 862–863, who also built the dome in front of the mihrab and lined the latter with beautifully carved marble panels, expressly imported from Iraq.

The most famous work of the Abbasid caliphs was the foundation of Samarra on the Tigris river, about 70 mi. N. of Baghdad, in 836. The palace stands on the edge of the plateau which is about 17 m. above the alluvial valley. It is built partly of kiln-baked, partly of sun-baked, bricks and the decoration consists of dadoes, generally of molded stucco, except in the throne-room group where they are of marble slabs. The scale of the whole layout is immense.

This palace was followed by the two Great Mosques of Samarra and Abu Dulaf. The former, as rebuilt in 852, is the largest mosque in Islam. Its outer walls, 2.65 m. thick of kiln-baked bricks with half-round buttresses at intervals of 15–16 m., form an immense rectangle 240 m. deep and 156 m. wide, in the favourite Abbasid proportion of 3:2. The area is nearly 38,000 sq.m. The flat roof rested directly on octagonal piers of brick with marble colonettes at the four corners, making a support roughly 2 m. square. There were no arches. The mosque proper was surrounded by an outer enclosure or *Ziyada*, measuring 376 × 444 m., and in this enclosure on the northeast side rose the minaret, the famous Malwiya, a tower with a spiral ramp about 2.30 m. wide which rises 6.10 m. for each complete turn. The total height to the top platform is 50 m. Between 860 and 861 another immense mosque was built at Abu Dulaf to the north of Samarra. It is 135 m. wide and 213 m. deep. There the outer walls are of mud brick 1.65 m. thick, with half-round buttresses, but the flat roof rested on arcades of burned brick at right angles to the *qibla* wall. The minaret is a miniature of the Malwiya.

In Egypt Ahmad ibn Tulun, a Turk born at Samarra, who had been appointed governor in 864, shortly after declared himself independent and decided to build a mosque in Egypt, of which the scheme of the outer walls and windows is Egyptian, being based on the exterior of the Mosque of 'Amr of 827. The decoration, however, is directly derived from Samarra. The mosque proper forms a great rectangle 122 m. wide and 140 m. deep; it is surrounded on three sides by open courts or *Ziyadas* about 19 m. wide, the whole forming a rectangle 162 m. square (or 300 Nilometric cubits, the unit of measurement used for setting out the mosque).

The *sahn* ("central court") is roughly 92 m. square, with five rows of pointed-arched arcades on the *qibla* side and two rows on the other three sides. The door soffits are of wood decorated with Samarra ornament, and the borders and soffits of the arches are decorated with stucco ornament. There are 128 windows filled with stucco grilles of geometrical design of which, unfortunately, only about four are original.

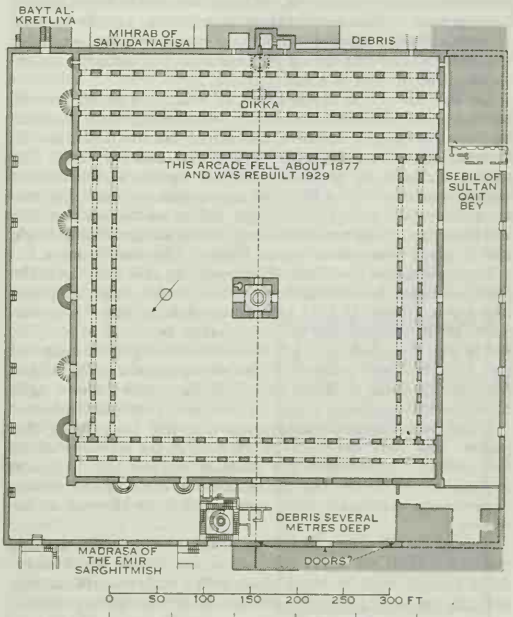

FIG. 3.—PLAN OF THE MOSQUE OF IBN TULUN, CAIRO

PERSIA

Only two mosques dating earlier than the middle of the 11th century have survived—the Tarik Khaneh at Damghan and the mosque at Nayin. The former consists of vaulted arcades on round piers running toward the *qibla* wall, the latter of arcades parallel to it, with stucco ornament derived from that of Samarra. But under the Seljuks in the last years of the 11th century, a new feature appears at Isfahan, a large dome 15 m. in diameter in front of the mihrab, covering nine bays of the sanctuary (3×3) and consequently opening into it on three of its sides by three arches. An inscription states that it is the work of Malik Shah (1073–92). This type is also found later at Gulpaigan, Ardistan (1158) and elsewhere. In the latter, part of an arcade on round piers with 4th-century stucco ornament has survived, proving that this great domed bay was an insertion into an earlier mosque.

The 12th and 13th centuries witnessed the development of faïence decoration. Dadoes were composed of star tiles in golden-brown lustre on a white background, and splendid calligraphic borders framed the mihrabs; *e.g.,* the famous mihrab of 1226 from the Maidan mosque at Kashan, once in the Preece collection but later moved to Berlin. But the 13th century also witnessed the greatest disaster that has ever befallen Persia—the Mongol inroads.

This Mongol terror caused an enormous migration of architects and craftsmen, not only to Asia Minor (where the inscriptions on the monuments of Konya and Divigri bear witness to it), but also to Cairo, which became the refuge of Islam from the Mongols. Al-Maqdisi says that "numbers of Orientals came to Egypt and built themselves homes on the banks of the Khalig and the Birkat al-Fil."

Persian mosques generally have a monumental entrance, consisting of a deep rectangular recess covered by a semidome resting on stalactites; *e.g.,* the Great Mosque at Veramin (1324) and the Masjid-i-Jami of Shah Abbas I at Isfahan. It seems probable that such portals are a development of the side bays of the caliph's palace (Bab al-'Amma) at Samarra, where this feature is seen in its simplest form—a rectangular entrance bay covered by a semidome on two squinches. During the Timurid period faïence tiles and faïence mosaic came more and more into use, and even greater surfaces were covered than had ever been before; *e.g.,* the Mosque of Jawhar Shad at Meshed in Khurasan, one of the finest examples of polychrome faïence mosaic ever executed, and similarly the remains of the Musalla at Herat.

The Safawid period (1501–1736), of which one of the greatest rulers was Shah Abbas I (1587–1629), was marked by his remarkable town planning at Isfahan; nothing of the sort had been attempted since the foundation of Baghdad and Samarra. The scheme included the great Maidan, or square, surrounded by vaulted bazaars, with the portal of his mosque opening in the centre of the south side, the Ali Qapu palace on the western side and the avenue over two miles long, known as the Chahar Bagh, with its plane trees and its famous bridge. (*See* also ISFAHAN.)

Many gilt domes date from this period; *e.g.,* the dome over the shrine of Imam Riza at Meshed. Jean Chardin (later Sir John) who was in Isfahan in 1673 after an earthquake, saw the copper-plates being made for the new dome: they measured 16×10 in. and he says that there were ten crowns worth of gold on each and that 3,000 had been ordered. Other examples exist at Najaf and Karbala (both due to Nadir Shah), Al Kazimiyah (due to Agha Mohammed Khan Qajar), Qum and Samarra (Fath Ali Shah).

Many truly monumental caravansaries were built during this period. Fine work was still being executed at the beginning of the 18th century, for example, the *madrasa* of Shah Sultan Husain at Isfahan (1700–10), but the disaster of the Afghan invasion hastened the decadence which was complete by the end of the century.

Persian minarets vary slightly in form—a tall, slightly tapering cylindrical shaft, of which the earliest example is the Minar-i-Ali at Isfahan, built by Malik Shah, with a little covered balcony near the top for the muezzin, who proclaims the call to prayer.

Persia was certainly one of the great creative centres of architectural development. For the science and skill shown in the construction of vaults, domes and pendentives, Persian architects must ever command respect and admiration, and in the field of polychrome decoration on the grand scale their achievements remain unrivaled.

TURKEY

Turkish architecture began when a branch of the Seljuk ruling family of Persia established itself in Asia Minor at the end of the 11th century. It therefore naturally bore a strong Persian imprint which was mixed in the 13th and 14th centuries with Syrian influences—in fact the Mosque of Ala ad-Din at Konya (1220) was actually built by a Syrian architect, Mohammed ibn Khaulan. In material the country had the advantage over Persia, for splendid limestone was available, hence the superb masonry and rich carved ornament of the monuments of Sivas, Divrigi, Konya, Kayseri, Amasya, Mardin, Nigde, etc.; *e.g.,* the Tschifte Minare (1271) and the Gok Madrasa (1271) at Sivas.

To this period also belong two magnificent caravansaries, Sultan Khan (1229) and the Ak Khan (13th century). One of the outstanding features of Turkish architecture is the monumental portal with a stalactite hood, but it is composed in a different manner from the Egyptian type. In addition there is nearly always a semicircular recess below to right and left, a feature never found in Egypt except in the *madrasa*-mausoleum of Sultan Hasan. The minarets were derived from those of Persia, together with the practice of having a pair flanking the entrance. In addition to Syrian influence, Armenian masons undoubtedly played an important part, and there can be little doubt that the many circular and octagonal mausoleums, domed internally but covered by a cone externally, were influenced by the *kempet* ("domes") of Armenian churches. The most pronounced example of Syrian influence is the Great Mosque (1375) of Aya Suluk near Ephesus, which is obviously based on the Great Mosque at Damascus.

With the conquest of Constantinople in 1453, an important change takes place in Turkish architecture. The supreme architectural qualities of Hagia Sophia had not led the Greeks to build other churches like it; it represented a line of development which had been, so to speak, frozen at birth. But after the capture of the city, the brilliant architectural instincts of the Turkish architects realized its supremacy over all other Byzantine monuments, and almost every important mosque built by them in their new capital is a variation of its theme. Apparently they wished to obtain a perfectly symmetrical building with one great dome, four semidomes and four small domes between them, and this was achieved in the Mosque of Ahmed early in the 17th century. But it is generally agreed that the most successful mosques built by them are those of Suleiman the Magnificent and of Selim II at Adrianople (Edirne), both designed by the famous architect Sinan (d. 1587). But whereas Hagia Sophia does not create a very good impression externally, below the springing of its piled-up dome and semidomes, the Turkish architects aimed at a good external effect also. The mosques of this period usually have four minarets, or even as many as six (*e.g.,* that of Sultan Ahmed), and the minarets usually have two and sometimes three galleries.

The most unfortunate event for Turkish architecture was the introduction of French and Italian architects and craftsmen by the French ambassador, the comte de Choiseul Gouffier, in the middle of the 18th century, the result of which can be seen in Istanbul in the Nuruosmaniye mosque of 1748–55 and later buildings.

EGYPT

In A.D. 969 the Fatimid conquest of Egypt took place, and the foundation of Cairo on unoccupied ground about 3 mi. N. of Al Fustat. The Mosque of Al Azhar was begun the following year, and although it has been much altered, it is easy to see that the original sanctuary was five aisles deep and the side aisles three; the north side was without a portico. A transept runs from the court to the mihrab, the five arcades stopping short on either side of it. The material used was brick, with stucco for the decoration.

Another great mosque was begun 20 years later and finished by the Fatimid caliph al-Hakim in 1003. It had a monumental entrance in the centre of the northwest side; there were also two

important lateral entrances flanked by several lesser ones. The sanctuary had five arcades resting on brick piers cut through the centre by a transept, at the end of which was a dome on squinches and there was a similar dome at each of the back corners of the sanctuary. The outer walls were of stone and the arcades of brick. There was a minaret forming a salient at the two ends of the main façade, as in the Great Mosque of Mahdia, the early capital of the Fatimids.

Cairo was refortified by Badr al-Gamali in 1087–92, the town having outgrown its original enclosure, and three splendid gates of fine masonry, the Bab al Nasr, Bab al Futuh and Bab al Zuweila (Zawayla), and about 400 yd. of the Fatimid wall still exist. Crusading influence is excluded, for they were built ten years before the first crusade left Europe.

One of the glories of Fatimid architecture was its ornamentation, both its decorative Kufic inscriptions and fine arabesque. It witnessed the beginning of Syrian influence, which increased under the Ayyubids and Mamelukes.

The Ayyubid period (1174–1250) was marked by the military architecture of Saladin, who built the mighty citadel of Cairo and part of the city walls, in which the most noteworthy feature is the bent-entrance (three in the citadel and two in the walls), the object of this device being to break the rush of a storming party. Other features of this period are the introduction of the *madrasa*, or theological college, the increasing use of hewn stone, the introduction of marble paneling for mihrabs, the development of stucco ornament in the direction of almost excessive fineness, the first use of glass in window grilles and the first steps in the evolution of the so-called stalactite pendentive.

The Ayyubid dynasty was followed by that of the Bahri Mamelukes (1257–1382). This period witnessed an important development in the mosque plan, in the Mosque of Baybars, where the small dome in front of the mihrab is replaced by a large dome covering nine bays (3×3) of the sanctuary. This feature was first introduced at Isfahan by Malik Shah and appeared later on at Ardistan (1158). It first appeared, outside Persia, in 1158 at Mayyafariqin, a region which was in close relations with the Egyptian court. This feature occurs again in Cairo in the Mosque of al-Nasir Mohammed in the citadel (1335) and in that of his cupbearer al-Maridani (1340). The Syrian number and arrangement of the doors (three axial ones) was also adopted. The stalactite portal was also introduced from Syria at this time.

A Persian architect was employed under al-Nasir Mohammed for the Mosque of Qusun, finished in 1330; this must be the explanation of the faïence mosaic which now appeared for the first time in Egypt, in the Mosques of al-Nasir Mohammed and Aslam al-Baha'i (1345), and in the mausoleum of Princess Toghai (d. 1349), and then suddenly died out. The period of the Bahri Mamelukes was also marked by the final development and gradual extinction of stucco ornament, and by the introduction of splendid dadoes of polychrome marble.

The architecture of the Burji Mamelukes (1382–1517) followed without any break in development. The rich stucco decoration, which had become extinct toward the end of the previous period, was not immediately replaced; at first the stone surfaces were left smooth and marble paneling was the chief enrichment, but when plastic skill in the new material was once acquired elaborate carved surface decoration once more became a regular feature. The stalactite pendentive underwent a change, the niches being set out Syrian fashion on a triangular frame; but, unlike Syrian pendentives, each tier is curved in plan instead of cutting across the corner in a straight line and there is a great increase in the number of tiers, seven, eight or nine being quite common. The domes of this period, always of stone, are without rivals for lightness, beauty of outline and richness of decoration; *e.g.*, in the mausoleums of Barquq, Qait Bey, Qani Bey, etc. Faïence decoration was employed again at the end of this period, but in the form of tiles instead of the more effective faïence mosaic of the previous century.

It has been the custom to belittle the Turkish period (1517–1798), but it is probable that the enormous reduction from the great amount of money spent by the rich Mameluke court was a more serious factor than an actual falling off in the quality of the work, and in Cairo the Mosques of Sidi Sariya in the citadel, Malika Safiya and Sinan Pasha at Bulaq justify this opinion.

FIG. 4.—PLAN OF THE MAUSOLEUM OF QAIT BEY, CAIRO, SHOWING (A) MIHRAB, (B) COURT, (C) SANCTUARY, (D) TOMB AND (E) HALLS

The houses of Cairo rarely had more than two stories: on the ground floor was the *salamlik*, or men's apartments, and on the floor above was the harem, or women's apartments. The chief feature of the façade, above the ground-floor level, was the attractive *musharabiya* balconies. The following rules are generally observed: (1) the principal rooms face north (the direction of the prevailing wind) and look into the court around which the house is built; (2) the passage leading from the street to the court is built with a right-angled turn to prevent passers-by from seeing into the court; and (3) the entrance to the harem is placed on the far side of the court or in a second court.

The first half of the 19th century witnessed the introduction of the Stambuli style under the dynasty of Mohammed Ali.

WESTERN ISLAM

The Muslim architecture of Spain began with the arrival of Abd al-Rahman I, the only one of the Omayyads to escape the hatred of the Abbasids. In 756 he established an independent amirate in Spain and in 787 built a mosque of cut stone at Córdoba. On the south side of the courtyard, which was not surrounded by porticoes until much later, was a sanctuary consisting of 11 aisles formed by 10 arcades of 12 arches each, at right angles to the *qibla* wall (there was no transverse arcade at the back as at Kairouan). The central aisle was wider than the rest. The supports were marble columns with many kinds of Corinthian and composite capitals, taken from other buildings. As these supports, with their capitals and bases, only measure about 3.80 m. an upper arcade was added, as in the Aqsa mosque, to obtain the height necessary to support a flat ceiling about 9.30 m. from the floor. The execution of this idea was carried out in a fashion somewhat different from that adopted in Syria, but it resembles the Aqsa mosque in that the aisles are roofed by parallel gable roofs with deep gutters between, which discharge by spouts placed above the piers of the façade on the court. The arches are built with stone voussoirs, alternating with composite voussoirs of four layers of red tiles ground down to a slightly tapering form. This alternation of colours is called *ablaq*. The existing Great Mosque of Córdoba consists of this original part of 787 to which have been added three enlargements, two to the south toward the river and a third consisting of eight more aisles which, space to the south being lacking, has been added to the whole length of the east side. The second enlargement, due to al-Hakam in 961, is of extraordinary richness, especially the part in front of the new mihrab, where a screen is formed of interlacing arches, supporting three elaborately decorated domes, each set on the square in a different way. The mihrab is decorated with carved marble panels and gold and glass mosaic, said to have been executed by craftsmen sent by the Byzantine emperor. The masterpiece of Muslim architecture in Spain is the beautiful Alhambra (*q.v.*).

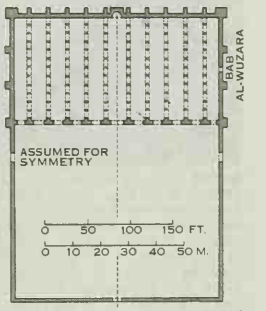

FIG. 5.—PLAN OF THE GREAT MOSQUE, CÓRDOBA, SPAIN

In north Africa the 12th century is marked by the decoration of the Great Mosque of Tlemçen (1135–36), which is of

extraordinary richness and beauty, especially the dome setting and the mihrab. A century and a half later came the superb decoration of the Great Mosque of Taza.

INDIA AND PAKISTAN

Although India was invaded by Mohammed ibn Qasim in A.D. 712 and again by Mahmud of Ghazni at the beginning of the 11th century, there is not a single example of Islamic architecture until the very end of the 12th century, when Mohammed of Ghor left Qutb-al-Din Aibak behind in India as the first sultan of Delhi. It is to him that the oldest part of the Quwwat al-Islam mosque is due, begun in 1193. This consists of a courtyard, measuring 105 × 142 ft., surrounded by pillared cloisters, short pillars from Hindu temples being superimposed to get the required height, the whole measuring 149 × 214 ft. externally. On the west (*qibla*) side the close setting of the columns is broken by five octagonal bays, presumably once covered by domes. All this was finished in 1196.

Then two years later a beautiful pointed-arched façade was built in front of the sanctuary, the central arch being wider and higher than the two to right and left. It was set in a rectangular frame which rose above the rest of the façade (a Persian concept known as a *pishtaq*, or frontispiece) and which consisted of bands of Hindu ornament and Nashki inscriptions. But these five arches are constructed with horizontal courses, for the Hindu masons employed by the conquerors were not acquainted with arcuate construction, and they employed the same technique for the arches when Iltutmish enlarged the mosque in 1229. It was in the mausoleum of Balban (*c.* 1280), however, that true arcuated construction made its first appearance. The mosque had three axial entrances and was accompanied by the first minaret in India, the famous Qutb Minar, closely related to those at Ghazni, Afg., and the minaret discovered at Jam (1163–74) in the 20th century.

This mosque, with its three axial entrances, cloistered courtyard and sanctuary with large central arch more or less set the standard type for India (*e.g.*, those at Delhi, Agra, etc.), except that this central arch is sometimes flanked by the massive bases of a pair of minarets (*e.g.*, at Ahmedabad, Dholka, Champaner, etc.). Indian minarets are generally tall, circular or octagonal towers, with several galleries and a domed pavilion at the summit.

Mausoleums form another outstanding feature of Islamic architecture in the Indian subcontinent. There are three main groups: a domed square; a domed central chamber surrounded by four smaller domes (*e.g.*, mausoleums of Khan Khanan, of Humayun and the Taj Mahal, *q.v.*); and concentric octagons (*e.g.*, mausoleum of Sher Shah Sur), the latter type being almost unknown outside India except for the Qubbat as-Sulaibiya at Samarra.

Unlike the Islamic architecture of Persia and Iraq, the Muslim monuments of India are characterized by their well-finished masonry and finely carved ornament, while the buff or red sandstone so frequently employed adds an attractive touch of colour.

ISLAMIC ART, the art of the followers of Mohammed, combined the influences of many regional cultures, extending from western Europe through the far east from the 7th century onward, into a unique style that attained its fullest development during the period between the 10th and 16th centuries. Islamic art is essentially an art of ornament.

Origins and Nature of Islamic Art.—In a world enclosed between desert and steppe and ruled by nomadic peoples, Islamic art inevitably followed an entirely different path from that of the west. Western classical art developed among settled tillers of the soil and in towns; it is intellectual. Characteristic of it is the clear structural consistency of architecture, which is carried on into architectural ornament. Naturalistic sculpture and relief, the portrayed figure, are preferred. The art of the nomads, on the other hand, proceeds from the tent and the loom, and for that reason the tectonics of Islamic architecture are limited to the primary forms, though they are frequently resolved into delightful shapes. Wall surfaces are adorned with purely geometrical decoration resembling rugs over the framework of a Kirghiz tent. Islamic decorative art is based on pure ornament, script, arabesque and intertwined bands. As in early Irish, Scandinavian and Romanesque art, representations of human beings and animals are combined with fillet and arabesque ornament, and in plastic art they appear only in low relief. Only in painting do they acquire an independent life under antique Sasanian and eastern Asian influences, but even so they are partly in the nature of calligraphy, against the background of an equally conventional, tapestrylike landscape.

Except in the most recent period, naturalism never existed. Added to this, the Arabian world had a dislike of figural art, already perceptible in eastern Christianity. Figural representations were absolutely prohibited in the early period of Islam and under the Berber dynasties of Africa and the Mamelukes of Egypt and Syria, though under the Omayyads and Abbasids and most of the Shi'ite and Turkish dynasties it was only excluded from public buildings. (*See* also BYZANTINE ART; ROMANESQUE ART.)

Plastic Art.—Plastic art on the larger scale therefore seldom fell under outside influences. Thus the Seljuks brought with them from eastern Turkistan a plastic tradition akin to the Buddhist art of central Asia; this tradition is represented by the few extant statues and reliefs of lions, double eagles, dragons, angels, etc., from the city walls of Konya and Baghdad, and by a few stucco plaques depicting scenes of court life. Apart from these, human and animal figures in low relief are found scattered here and there among the decorative carving on rafters and beams dating throughout the period from the 11th to the 14th century. Under the Mogul emperors in the 16th and 17th centuries Indian influence appeared in the elephant statues of Fatehpur-Sikri and Delhi. Sasanian influence appeared in the 19th century in the rock reliefs of Fath 'Ali Shah of Persia. Other plastic art, however, was entirely restricted to small-scale works, chiefly figures of lions, elephants and birds in glazed stoneware or bronze, strongly conventionalized as the nature of the material required, and used as water vessels or smoking appliances. A madonna with Mongolian dress and appearance, made of faïence, is an exception.

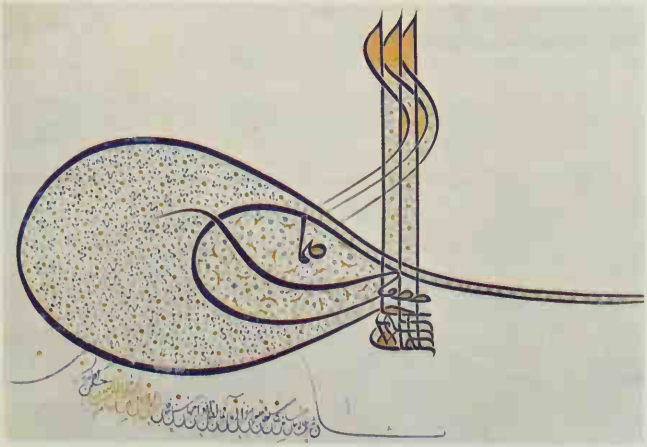
Painting.—Figure painting was much more important. It is true that it was excluded from public, political and religious edifices. In the private apartments, however—bathrooms and harems especially—painting was tolerated by the clergy, and found its expression in frescoes, illustrated erotic and edifying books, and household vessels, goblets, bottles, etc., adorned with figures. Even the caliphs decorated the private apartments in their palaces in this way. Thus between 712 and 715 the Omayyad al-Walid had the bathrooms in his desert castle of Qasr 'Amrah painted throughout with frescoes in the later antique style, depicting birth and death, the three ages of life, hunters and hunting animals, musicians and dancing girls, women bathing, the caliph on the throne, the emperors overthrown by Islam and so on. The latter group betrays the influence of Sasanian art, which dominated the harem frescoes reconstructed out of scanty remnants in the Abbasid residence at Samarra (836–876). There are found danc-

ISLAMIC ART OF THE 14TH AND 16TH CENTURIES

Albarello decorated in underglaze colours. Sultanabad, Persia; 14th century. Height 13 in.

Vase decorated in blue and turquoise. Isnik, Turkey; 1530–40. Height 15½ in.

Above and below: Painted lacquer bookbindings. Persia; c. 1540. Height 15½ in., width 9¾ in.



Calligraphy: ornamental cipher of the Ottoman sultan Suleiman the Magnificent (1520–66). Size 13½ x 24 in.

ISLAMIC ART

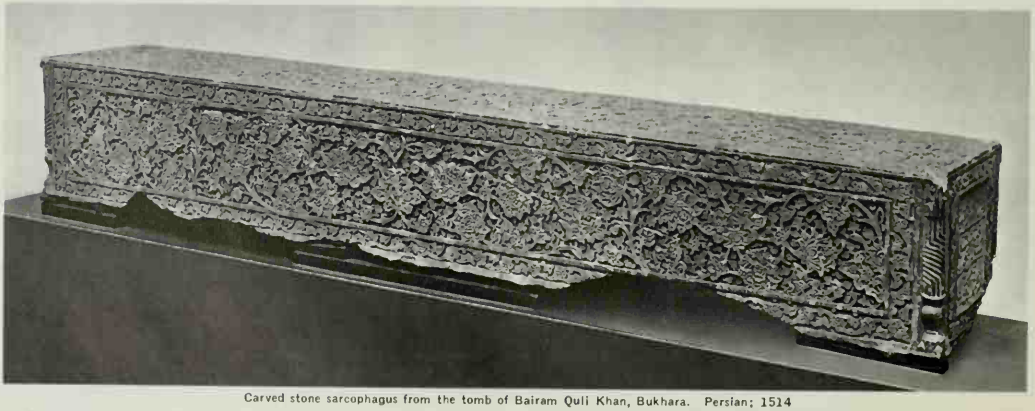
Ewer of brass inlaid with silver and copper. Mosul, Iraq; 1232. Height 12 in.

Shield of decorative basketwork with boss of damascened steel. Turkish; 16th century. Diameter 59 cm.

ISLAMIC ART FROM THE 10TH TO THE 16TH CENTURY

Rock crystal ewer, wheel-cut. Egypt; 11th century. Height 21.5 cm.

Bowl with decorative script in black slip on white ground. Nishapur, Persia; 10th century. Diameter 13 in.



Carved stone sarcophagus from the tomb of Bairam Quli Khan, Bukhara. Persian; 1514

BY COURTESY OF (TOP LEFT, SECOND ROW CENTRE) THE TRUSTEES OF THE BRITISH MUSEUM, (TOP RIGHT, BOTTOM) VICTORIA AND ALBERT MUSEUM, (TOP CENTRE) TOPKAPU SARAYI MUSEUM, ISTANBUL, © MUSEE DES ARTS DECORATIFS, PARIS, 1953, EXPOSITION "SPLENDEUR DE L'ART TURC"

ing girls in a variety of poses, naked and in flowing robes, with diadems and long braided hair, with floating veils, bowls and wine jars; huntresses and horsewomen, priests and warriors, and animals of every kind, in a heraldic style on medallions composed of intertwining tendrils and bands in endless repetition, symmetrical and hieratic.

In the Alhambra (*q.v.*) at Granada (13th–14th century) the last Moors of Spain were represented as noble knights and troubadours in roof paintings of an almost Gothic style. In the frescoes and faïence tiling of the castles of Isfahan and Ashraf, displaying exquisite calligraphy, and betraying strong eastern Asian influence, the amorous and oenophilous sentiment of the courtly youth of the Safawid era were represented. In India, the harem apartments of the 16th- 17th-century Mogul rulers were painted throughout with frescoes, though these were discarded about 1700 by the orthodox emperor Aurangzeb; but wall paintings, some with Buddhist subjects, have been preserved in the bedroom of Akbar's soon abandoned residence at Fatehpur-Sikri, and from a few contemporary miniatures are known the semi-European paintings that Jahangir caused to be executed at Agra. (*See* also PERSIAN ART: *Painting and Calligraphy.*)

Ornament.—Ornament is the centre of Islamic art. It supplanted all the other possibilities offered by different individual techniques. Utilizing them all, dependent on none, it is a self-contained world of form, which embraces indifferently the walls of mosques and castles, the backgrounds of figure paintings, the details of sculpture, glasses, pots and vases, furniture and bronze implements, arms and jewelry, bookbindings and calligraphy, a vast storehouse of forms, turning every technique, every material to its own uses in the most perfect taste.

The motifs from which this ornament grew came from the later antique, the ancient east and the barbarian migrations. In the earliest monuments, particularly the great frieze in relief at Mshatta, the prevailing feature, as in Byzantine and Romanesque art, was the spiral tendril springing from the vine, its spaces filled in with vine leaves and branches of grapes, and diversified with animal figures and large rosettes. In the frescoes and in the third style of the stucco wall facings in the Abbasid residence at Samarra the same motif is found, though greatly conventionalized.

Beside it, however, is encountered a new type of ornament undoubtedly traceable to the wood carving of the nomad tribes of the north, consisting of palm leaves, whose contours soon became an independent style, a complex of free curves. Under the Turks and the Arab dynasties that took their artistic notions from them (10th to 16th century), this developed into a purely abstract art of decoration; its leading motifs are the fillet, the arabesque and the palm leaf.

The fillet is the most important and is derived from the northern nomadic art. Plain or twisted, with herringbone or circular patterns, it divides every area into border and central field, angle and centre medallions, friezes, etc. It curves into circles and wavy lines, imitates the shapes of architectural vaults, piles up tendrilwise in vaulted arcades and forms complicated trellis patterns. This developed into the twined pattern of stars and rosettes favoured during the Mameluke period, which presents designs that, numerous though they are, are always mathematically accurate. The intervening spaces are filled with polygons, stars, garlands, rosettes, often plain or in simple patterns that secure their effect through colour contrast, and frequently are decorated with rich arabesques diversified with palm-leaf motifs.

The early twining vine leaf, the palm leaf, the tree of life of the ancient east, are combined in an inextricable dramatic unity, enriched since the Mongol period with completed palm leaves and even with distortions of these into diabolical masks, houses, etc., and Chinese cloud strata and shreds. Thus western Asia, especially Persia, was dominated by the arabesque, in delicate spirals, often of the shape of snail shells, with little rolled-up and not uncommonly pinnate leaves, and rosettes, and palm leaves radiating outward. It served also as a background for decorative figures of phoenixes and Chinese dragons, hunting animals and birds, musicians and dancing girls, but most of all for ornamental inscriptions.

The clumsy early Arabic script, the Kufic, with its numerous vertical and oblique strokes, produced an extraordinarily monumental effect, and for that reason, it continued to be employed as a decorative writing, and developed into a new form, used with special frequency in Persia—the floral Kufic, in which the top of the characters blossom into floral tendrils. This was also combined with the trellis ornament, a notable example being the stuccowork in the Alhambra at Granada. The later cursive *naskhi*, with its wealth of curves and twists, also proved a highly decorative script, the final letters of words being generally crossed with the long strokes of the initial letters like an ornament. They were also frequently used to provide a delicate background to the heavier characters of the Kufic. The shikasta and the animal figures which were artfully formed from the characters of some sentences (generally from the first sura of the Koran) were confined, however, to the Persian book-designer's art.

After the 16th century Islamic ornament began to decay. As early as the 13th century niches framed by arches and pillars, vases with bouquets of flowers, hanging lamps, cypresses, etc., had appeared sporadically; these now came into favour as decorative motifs, and their seminaturalism drove out the wealth of abstract ornament.

Architectural Ornament.—Since tectonic arrangement in architecture was confined to the broad lines, a wide field was presented for ornament. In the Omayyad period preference was given to the glittering glass mosaic and deep-shadowed pierced stone filigree work, both common in Byzantium. With the victory of the sun-dried brick under the Abbasids, these were superseded by stucco facing sometimes molded in the flat, sometimes likewise cut in high relief, as in the third style of Samarra and in wonderful inscriptions in floral Kufic from Persia, all originally richly painted.

Later, in the Turkish and Mongolian periods, stucco gave way to the cheaper substitute for the more costly mosaic, in freestone or brick, but most often in faïence tiling. The less important parts of the rough core of the wall, often carelessly put together, were overlaid with a particoloured mosaic of glazed bricks of varied shapes, making twined patterns and formalized Kufic words endlessly repeated; while the major portions were covered with mosaics of tiles cut skilfully to the exact shapes of the prevalent patterns, in harmonious colour schemes, particularly blue, or in combinations of faïence ornament on a stucco ground (in relief) or friezes of inscriptions in incised stucco in the intervals of faïence mosaic. Admirable also are the script friezes of glazed tiles with dark blue characters on a ground of golden-brown arabesques.

With the decay of ornament after the 16th century, this type of mosaic was generally supplanted by square faïence tiles with painted decoration. Apart from one or two magnificent portions of buildings, Syria, Egypt and the west were content with coloured stuccowork and mosaics of particoloured stone plaques, generally white and red or white and black. (For plan and tectonics *see* ISLAMIC ARCHITECTURE. *See* also ORNAMENT, ARCHITECTURAL.)

Furniture.—Another reason for this rich wall decoration lies in the almost complete absence of furniture, in the western sense of the term, in Islamic places of worship and dwelling houses. This, like the custom of sitting on the floor, was due to the nomadic habit. Household crockery was kept in stuccoed recesses in the walls, or on wooden shelves and in cupboards built into the walls.

Furniture was represented in private houses by small, low, round or oblong tables, and in India also by beds. Chairs came into use in the 17th century only in the highest circles. In the mosques the Koran was placed on a desk (*kursi*) like a campstool, and was often kept in a small circular cabinet; the pulpit (*minbar*) was a domed box at the top of a staircase, reached through a doorway that could be closed.

A feature of most of these objects is the way in which they are decorated with tarsia work of small boards, richly carved and inlaid with mother-of-pearl, ivory, etc. This was necessary because of the wood available and the danger of warping. The harem doors were worked in like fashion, often with rich bronze

ornamentation, and the balcony railings (*musharabiya*), made of small curved wooden pales. (*See* also Wood Carving.)

The remaining objects in the house comprised rugs and cushions, jewel cases and boxes, table utensils, lamps, smoking equipment, open charcoal pans (as stoves) and warming pans, candlesticks, etc., in bronze, faïence, glass, ivory and other materials. For rugs and woven fabrics, *see* Embroidery; Rug and Carpet; Textiles.

Ceramics.—The Islamic ceramic art built upon ancient oriental traditions, enriched them for its own religious purposes with a new and highly effective technique, and pursued its development under growing influences from eastern Asia.

The use of the coloured glazed brick was inherited from Babylon, as was the unglazed earthenware in the barbotin style (in which the pattern is made by applying bands of clay) with the tree of life and naked goddess (Astarte) motifs, enriched with Hellenistic and Sasanian elements, laurel and acanthus leaves, stubs of palm leaves, and later wreathed medallions centred with animal figures, griffins, eagles and the like. Examples are to be seen in the pottery of Samarra, though this is almost entirely in tiny shards. Echoes of this barbotin technique appear in the ware of Mosul down to the 14th century, and in the Gabri ware of Persia, in the sgraffito manner, often with lively painting, until *c.* 1200.

Contemporaneously, in Samarra, appeared the first lustreware. Early Islam was puritanical enough to proscribe gold—like silk—as a worldly luxury, and for that reason, in later times, faïence painted with a gold lustre changing to green, brown and violet was used as a substitute; in the earliest examples the forms of the magnificent golden and silver vessels of the Sasanian epoch can still be plainly traced. This style rose high in favour, particularly in the Seljuk and Mongol periods, but disappeared at the beginning of the 17th century. The Abbasid caliphs also imported porcelain, from China (Sung dynasty), and imitated in earthenware its white, yellow and green overflow glazing and its stippled, fish and other designs. With the Seljuks came a new wave of far eastern influence, the chief centre of the industry under their rule being Rhagae, the forerunner of Teheran.

Minai ware consisted of bowls, beakers, tankards and bottles with spirited painting and gilding on a white ground, often with rich figure compositions in bands. There are also vessels of similar types as well as some akin to the bronzes, in animal and human form; their design is left white, generally on a ground of violet lustre, and shows the classical arabesque and palm-leaf motifs, sphinxes and birds with crowned women's heads, peacocks, elephants, scenes of court life and war, and, above all, horsemen with their characteristic pigtails and their garments adorned with arabesques. After the destruction of Rhagae by the Mongols, Sultanabad and Veramin became the centres of the ceramic industry in the 13th and 14th centuries. Favourite types were not only *minai* and lustreware, but also faïence in green and dark blue tones, in many cases with molded ornamentation, and tiles richly decorated in lustre. From the 16th century onward, Chinese white porcelain with blue and gray designs was imported in large quantities and became a regular type. Its decoration was copied and freely developed, but porcelain itself could not be successfully manufactured, and a kind of semifaïence, closely resembling it, was made instead.

Persian pottery formed the basis of that of Syria, Egypt, Spain and Asia Minor. In the Arab civilization, figure motifs disappeared early, and bands of script or arabesque, arranged radially or in rings, became the prevalent form. In Spain, under Christian rule, this art developed still further, and absorbed Gothic motifs; the 14th- and 15th-century wares of Málaga (whence the name majolica) and of Paterna and Manises, two suburbs of Valencia, exercised a very strong influence on the majolica ware of the early Italian Renaissance. On the other hand, in the Ottoman pottery of Kutaiah and Isnik (Damascus and Rhodian ware), which flourished from the 15th century onward, relatively naturalistic tulips, carnations, roses, lilies, cypresses, etc., and also figure subjects, were preferred for purposes of decoration, cobalt blue, turquoise, green and manganese violet being used as colours, generally on a white ground. (*See* also Pottery and Porcelain.)

Glassware and Crystalware.—Unlike pottery, glassmaking was inherited from Hellenic antiquity and was centred in Syria and Egypt. The Fatimid period produced narrow-necked bottles, tankards and beakers, and scent bottles ornamented with externally applied bosses, threads and bands, or with spiral tendrils and animal figures molded into the glass. In addition, imitations were made (Hedwig glasses) of rock crystal vessels with ornament consisting of figures and circular tendrils, of Sasanian origin. Many of these came early into the possession of religious or noble houses in Europe and have thus been preserved. The finest work, however, was produced at Aleppo in Syria, under the Ayyubid and Mameluke dominations. Bottles, beakers, goblets and above all hanging lamps for mosques were covered with bands of arabesque and script and with medallions in enamel colours (white, red, blue and yellow) and gold; the subjects included figures of horsemen and others, and the coats of arms of the court offices. Modern Persian glass originated in the industry promoted by Shah Abbas I (*c.* 1600). (*See* Glass.)

Metalwork.—Here again oriental traditions, particularly those of the Sasanian empire and the far east, predominated. Most of the work was in bronze, iron being still used almost only for weapons. The use of gold and silver also was limited, because it was forbidden by the Koran; and although the prohibition was often ignored, the great value of such objects led to their early destruction and melting down. Islamic jewelry of the early period is therefore of extreme rarity, being represented only by a few buckles, bracelets, etc., of the Fatimid and Mongol periods, and such pieces as the Gerona silver chest (akin to the similar ivory coffers) in Spain and the Berlin silver tankard of the 13th century, with its embossed reliefs of Sasanian animal friezes. (*See* Jewelry.)

Bronzes.—Such animals in the Sasanian style, lions, dragons, sphinxes, peacocks, doves, cocks and the like, were also cast in bronze in three dimensions, and served, like their ceramic counterparts, as basins, braziers, etc. They were particularly sought after in the later Abbasid, Fatimid and Seljuk periods, and from Egypt they became the prototypes of similar European forms. It was the Seljuks, apparently, who introduced the round bronze mirror, the reverse of which shows in low relief either two sphinxes face to face—in the manner of the *minai* pottery—surrounded by a twined pattern, or two friezes with the astrological symbols of the seven chief heavenly bodies (sun, moon and the five nearest planets) and the 12 signs of the zodiac, surrounded by a band of script; this goes back ultimately to Chinese origins.

Early mugs, etc., were ornamented with animals in low relief, but engraving quickly supplanted this. Under the later Seljuks (particularly the Ortoqid Atabegs of Mosul) and the Mamelukes, engraving became almost the only form of decoration, but only to serve as a basis for the yet richer technique of inlaying: small silver plates and wires, themselves delicately engraved, were hammered into the ribs and surfaces, which were hollowed out and undercut at the edges.

In place of this, in an Ortoqid bowl in the provincial museum at Innsbruck the spaces are filled in with cellular enamel. This was a method of evading the prohibition of precious metals, just as gold lustre was in pottery. The ornament consisted of friezes and medallions in lattice and arabesque work, the interstices being filled with figures of warriors, hunters, musicians, animals and astrological symbols. These were superseded later by Mameluke coats of arms and inscriptions. In the 15th century the technique was imported from Syria to Venice, where productions of the same kind, *alla damaschina* or *all' azzimina*, were made right into the 16th century by Islamic masters, and were in great demand. In the east the process is still common, but both technically and artistically it has decayed.

In the 15th century there was a renascence of pure metal engraving, but the design—inscriptions and arabesques in the Timurid and Safawid styles—was not cut into the material, but left free in the manner of a relief, the background being etched in black. Decoration was applied to bowls, basins, mugs, vases, mortars, braziers, warming pans, candlesticks, smoking utensils, inkstands, jewel cases, Koran holders, mosque lamps and *kursis*. These are

generally in the simplest possible forms—spherical, cylindrical, prismatic—and are developed by cutting off corners, adding projections, narrowing and channeling the walls, and by reduplication; the subjects include motifs of vegetation and animal life—the former mainly in the necks and feet of vessels, the latter for handles and ears, feet and sometimes small spouts.

Weapons.—Ancient Islamic weapons of any artistic value are comparatively rare: most of the extant pieces date from the 17th or 18th or even early 19th century, while the period from the 14th to the 16th is represented by a fair number of fine examples. Islamic swords were famous even in antiquity for their wonderful blades of Damascus and Toledo steel. This high standard was attained partly by a laborious process of repeatedly welding together pieces of iron of different qualities, but ultimately it was due to the peculiar process used for smelting the Indian raw material—a method whose results have been surpassed only by those of the modern Bessemer process. The earlier blades are all straight; curved sabres and daggers did not become common until after 1500.

The blades were ornamented with inlaid work of gold and silver threads, arabesques, dressings and—on the celebrated Mongol blades—also phoenixes and dragons in the Chinese manner; at a later period the inlay was confined to the part near the hilt, the remainder being adorned with engraved reliefs. For the handle and guards, gold and cellular enamel were used, as on the magnificent Boabdil swords named after the last Moorish king in Spain (15th century), with their hooked guards, and many Ottoman and Persian daggers and sabres of the 17th and 18th centuries. Nephrite, ivory and silver plating with jeweled ornament were also used, especially for daggers.

Scabbards had ornaments to match the hilts, and were covered with nielloed silver plating, leather, snakeskin or rayskin. Battle-axes and maces are also found, though these were often mere symbols of command and high position. The former display not only inlay but also in many cases engraved relief and even filigree work. The heads of the maces were often made of rock crystal but more frequently were cast solid, in a smooth pear shape, with grooves or bosses, richly inlaid. Shields were round with a boss in the centre: in Egypt under the Mamelukes they were of inlaid iron, elsewhere generally of leather, with painted lacquer surface.

The armour, of Sasanian origin, consisted of a mail shirt, arm-pieces and greaves, a round breastplate and a pointed helmet consisting of several spangles riveted together. Not until a late period did a coat of four plates (*char-aina*), and even a cuirass in the Spanish manner, become common. From the 15th century onward the helmet was made in one piece, though there were in addition a number of movable parts such as nosepieces, cheek-pieces, neckpieces, etc. The decoration, however—grooves or medallions between radiating ribs on a broad frontlet—betrays the original construction. The earlier pieces (15th century) were broad and protuberant, and came so low down over the forehead that eye notches were necessary, the reason for this shape being that the turban was worn under the helmet; the later examples fitted closely, and were pointed or hemispherical with spikes attached, nosepieces and crests.

The usual ornamentation in the early helmets, most of which are ascribed to western Turkistan, consists of silver-wire inlay; later, in Persia, it is generally iron engraving, sometimes combined with inlaid work; and in the grooved Ottoman storm helmets, black etching. An offshoot of the last named is the *Zischägge,* often richly worked, which was used in the 17th century in Hungary, Poland and even Germany.

Bookbinding and Lacquering.—Koran manuscripts and also rich miniature books were all bound in leather, the edges being protected by a flap. A very old binding from Egypt shows inlaid work, but apart from this the usual decoration up to the 15th century consisted of stamping with beaded edges, medallions in the centre and in the corners triangular ornaments of unobtrusive script, plait and palm-leaf patterns. From the 16th century onward, however, this decoration was transferred to the inner side of the cover, in finely detailed filigree work against a brightly coloured background. On the outside it was replaced by opulent stamped gilding which was indeed of similar composition but was formed of arabesques and bands of clouds, and even of decorative figure groups; sometimes also the outside was covered in the Chinese manner with lacquerwork, which in the early period showed occasional dragons and phoenixes, and later flowers and romantic and genre scenes. From the end of the 18th century this technique was in high favour, and was applied not only to bookbindings, but also to writing cases, jewel cases, toilet accessories, and even shields and bows. (*See* also BOOKBINDING; LACQUER.)

Development and Influence.—In its early period Islamic art continued the assimilation of Hellenistic and ancient oriental motifs begun by the later Persians, and from the Abbasid era it fell almost wholly under the tradition of the Sasanian empire. With the rise of the Turkish dynasties the nomad character became increasingly marked, and from the Seljuk period onward the influence of eastern Asia grew in strength, particularly from the Mongol to the Safawid period. Meanwhile Islam fused all these influences into a completely individual abstract style, which reached its zenith, artistically and technically, between the 10th and 16th centuries. Thereafter decadence began, veiled in the 17th century by extravagance of external splendour but betrayed by a tendency toward some degree of naturalism and an increase of European influence. By the middle of the 19th century Islamic art was in complete decay.

During its greatest period, however, its influence extended through India as far as Java, to China, to the Sudan and to the whole of Russia. The European culture of the middle ages and the Renaissance was very largely derived from it. Islamic brocades and carpets, ivories (coffers and olifant horns), glasses and *aguamaniles,* etc., found their way from Spain, Sicily and Fatimid Egypt into the ecclesiastical and princely treasure houses of Europe; in the period from the crusades to the conquest of Granada the borrowings consisted mainly of Mameluke weapons and glass, *azzimina* bronzes, Toledo blades and majolica ware from Spain, albarellos, etc., and bookbindings. In the east the Tatars brought their culture and art, especially weapons and clothes, to the Russians. Further, through the Turkish wars various Islamic utensils and *objets d'art*—stuffs, costumes, rugs (Polish rugs), sabres, helmets, etc.—became naturalized in Hungary and Poland, and even in Austria, Saxony, Bavaria and Prussia. *See* also PERSIAN ART.

ISLAMIC LAW. The life of a Muslim is traditionally governed by the twin sciences of theology and law. Theology teaches him all that he must believe, while law tells him all that he must do and leave undone. Law plays the primary role; for Islam has always been much more hesitant in its apprehension of the person of the God of revelation than in its elaboration of the precepts that he has revealed.

The sacred law (*shari'a,* literally "road to a watering place," hence the path of God) differs, therefore, from the western idea of law in three fundamental respects. The first is that it is much wider in its application, for it includes all human action in its scope. According to a widely accepted classification, every act or omission falls under one of five categories: what is commanded, recommended, left legally indifferent, reprobated or positively forbidden by almighty God. To the Muslim, therefore, the *shari'a* includes all that a westerner would term law—public and private, national and international—and a great deal which he would not regard as law at all, such as the details of religious ritual and

the ethics of social conduct. It is obvious, of course, that much of this amalgam of law and morals could never be enforced by any court, and much which falls even within the categories of things positively commanded or forbidden is regularly left to the sanctions of eternity.

Secondly, the *shari'a* differs fundamentally from western law in that it is not, in theory, man-made but grounded in divine revelation. In the strictest theory, indeed, there is no other means of evaluating the ethical quality of human actions; for not only is man incapable of perceiving this ethical value apart from divine revelation but human actions have no inherent virtue or vice except insofar as they have been commanded or forbidden by God. And to the orthodox Muslim the fount of revelation dried up forever with the death of Mohammed, a fact that of itself explains the third peculiarity of the *shari'a*, namely, that it is regarded as virtually immutable.

Origins.—In the classical theory, the law is believed to have rested, in the earliest days, on the Koran (*q.v.*; as the very word of God) and on the Hadith (*q.v.*), or traditions of the Prophet (as establishing his Sunna, or practice, which was also divinely inspired), together with the opinion (*ra'y*) of the earliest jurists on points not covered by the texts. But juristic opinion was soon felt to be too subjective and too fallible a source for the divine law; too subjective, so that the unfettered range of juristic opinion was soon restricted by precise rules of analogy (*qiyas*); and too fallible, so the view prevailed that, although an individual jurist might err even in his application of analogy, where the jurists as a whole could be seen (or considered) to have agreed, this was held to be a guarantee of divine authority. Thus, in the classical view, the four major sources from which the law was derived were the Koran, the practice of the Prophet, the consensus of the scholars and analogical deductions from these three.

Orientalists have shown, however, that this theory represents a considerably formalized, and even distorted, picture of how the law did in fact develop. For the first few decades after the death of Mohammed (A.D. 632) the Muslim community was too absorbed by the problems of administration arising from extensive military conquests to concern itself deeply with the elaboration of law. At a fairly early date, however, a class of pious scholars grew up who began to review the customary law and administrative practice of the Omayyad period in the light of Islamic norms and to accept, reject or modify them accordingly. They thus sought at the same time to Islamicize and systematize, and it was from their efforts that, around the end of the first century of the Muslim era, the *shari'a* began to take shape.

This explains how the *shari'a* could have been influenced—as, in part, it was—by Roman, Byzantine, rabbinic, canon and Sasanian law. It was not that the Muslim jurists deliberately studied and adapted other systems, but during the whole of the first century they were open to outside influences, whether in the form of the customary law of the conquered territories or the mental heritage of converts to Islam. It was thus that the replies of the learned (*fuqaha'*) in Islam followed the pattern of the *responsa prudentium* of the Romans (*see* ROMAN LAW), and it was thus that a number of specific rules of law of alien origin became incorporated in the *shari'a*.

Schools of Law.—Around the turn of the first century these pious scholars began to draw together on a regional basis and to form the ancient schools of law—the most important being those of Iraq, Syria and the Hejaz. In these schools the term *sunna* was primarily used for what has been termed the "living tradition" of the locality, and they strongly opposed the attempts of the traditionists to overthrow their doctrines by an appeal to alleged traditions of what the Prophet had himself said, done or allowed. It was only through the influence of al-Shafi'i (*q.v.*) that three major developments occurred. First, the basic thesis of the traditionists—that any "authentic" tradition of how the Prophet had himself behaved must be accepted as authoritative—came to prevail. Second, the classical theory of Islamic jurisprudence (which Shafi'i had himself elaborated) gained general acceptance, except only that he failed in his attempt to substitute the consensus of the entire community for the consensus of the scholars, so that it was still the jurists who decided whether an alleged tradition should be accepted as genuine or not. Third, the schools of Iraq and Medina, in imitation of the "companions of Shafi'i," began to call themselves after the names of two of their own leading scholars, Abu Hanifa (d. A.D. 767) and Malik ibn Anas (d. A.D. 795).

But although Shafi'i accepted the central thesis of the traditionists, he was much more exacting than they in his scrutiny of alleged traditions and fully accepted the need for the use of analogy, the rules for which he was the first to elaborate. And while his theory of jurisprudence won general acceptance, the Hanafis retained the doctrine of *istihsan* (juristic preference) as an alternative to the more obvious dictates of analogy, and the Malikis retained the doctrine of *istislah* (public welfare) as a principle to decide cases not directly covered by the texts. The more extreme traditionists, moreover, were far from content with Shafi'i's position, and the school of the Zahiris (now extinct) sought to discard analogy as a source of law and confine themselves to the indication (*madlul*) of the texts as a method of application. It was, however, the disciples of a traditionist named Ibn Hanbal (*q.v.*) who formed the only other school of law to survive in Sunni Islam. This school was strongly traditionist and, at the beginning at least, preferred to base its rules on even poorly attested tradition rather than on analogy; however, in the end it came to accept the same theory regarding the sources of the law as did the other schools.

Malik ibn Anas, the eponymous founder of the school of Medina, compiled the earliest extant legal text, the *Muwatta'*, while the earliest compilation of traditions as such is attributed to Ibn Hanbal. This is termed the *Musnad*, which signifies that the traditions are arranged according to the companion of Mohammed to whom they are traced back. Soon, however, a method of compiling books of traditions more convenient for the lawyer was devised, for in the collections called *Musannaf* the traditions are arranged according to their subject matter. The most famous of such collections are those of al-Bukhari and Muslim ibn al-Hajjaj (*qq.v.*)—both termed the *Sahih* (or authentic) and characterized by the acceptance of only those traditions which passed severe (but wholly inconclusive) tests of authenticity. Four other books of traditions, which adopted a considerably less exacting standard, eventually gained general acceptance along with these two as the six "canonical" collections. But J. Schacht and others have proved that the whole corpus of the traditions, while providing excellent evidence for the history of thought in early Islam, must be regarded as exceedingly dubious in its alleged attribution to the Prophet.

The four schools of law that have survived in Sunni Islam—the Hanafi, Maliki, Shafi'i and Hanbali—differ from each other in many particulars, yet each acknowledges the orthodoxy of its fellows. Their distribution is mainly, but not exclusively, geographical. The Hanafis are much the most numerous and widespread, partly because, whereas previously judges of different schools had coexisted in the main centres of Islam, the Ottoman empire accorded official recognition to the Hanafis alone. Most Muslims in central Asia, India and Turkey, and many throughout the middle east, are Hanafis; the Maliki school prevails throughout northern and western Africa, in the Sudan and parts of the Persian gulf; the Shafi'is preponderate in eastern Africa, parts of Arabia and throughout southeastern Asia; and the Hanbalis, now the least numerous, are chiefly limited to the Wahhabis of central Arabia and parts of the Persian gulf.

But besides the orthodox schools, various heterodox schools of law have also survived. Such are the Ibadis in Oman, Zanzibar and parts of northern Africa—the only survivors of the Khariji rebels of early Islam. Such, too, are the main subsects of the Shi'a: the Zaidis in Yemen, the Ithna 'Asharis in Iran, Iraq, India and elsewhere, and the Isma'ilis (*see* ISMA'ILISM), whether of the Nizari faction (who mostly acknowledge the Aga Khan as their leader, are commonly called Khojas and are found in India and eastern Africa) or the Musta'li faction (who are found in India and Arabia and are commonly termed Bohras). The Shi'i (Shi'ite) schools are chiefly distinguished by their attachment to

an imam as the infallible leader of the Muslim community. (*See* also SHI'ISM.)

Later Developments.—In the earliest days every adequately qualified jurist had the right to go back to the original sources and apply them to each problem which arose. This was known as the faculty of *ijtihad*, and one who exercised it was termed a *mujtahid*. But with the crystallization of the schools under the Abbasids this faculty was held, in orthodox Islam, to have fallen into abeyance from about the end of the third century of the Muslim era; all subsequent generations of jurists were held to be bound to accept the decisions of their great predecessors as authoritative. This is known as *taqlid*, and one who is bound by it is a *muqallid*. It was thus that, after the golden period of legal development, the law became more and more static and moribund; for, as the years passed, a dominant opinion asserted itself—in the texts, the courts and the *fatawa* (opinions) of the muftis (jurisconsults)—in almost every particular, in each of the four orthodox schools. The Shi'is never followed the Sunnis in this respect, and their leading jurists are still recognized as *mujtahids*, but in practice the Shi'i law is little more elastic than the Sunni.

Another salient feature in the *shari'a* is its remoteness, in many respects, from the daily life of the people. Developed largely by pious specialists and academic lawyers rather than based on the actual decisions of the courts, it grew up, in part at least, as a protest against current practice and was never really enforced as a whole. In particular, the maintenance of public order was, from a very early date, largely entrusted to the executive and the police; the *qadis* or regular judges were bound by the *shari'a* to so rigid a system of evidence and procedure (in theory at least) that no Muslim ruler would leave the administration of criminal justice wholly in their hands. Much the same was true of the life of the markets, where the merchants found the strict prohibition of usury and of speculative contracts impossibly restrictive. The gulf between law and practice was, indeed, partially bridged by a system of legal devices invented by the lawyers themselves, so that what would otherwise be forbidden might be accomplished indirectly and without any open infraction of the law. It was in the law of family relations—marriage, divorce, guardianship and succession—that the *shari'a* found its fullest expression.

Still, the fact remains that until about 1850 the *shari'a* was, in theory at least, the only law. Local customary law (*'adat*) or the commands of the executive (*qawanin*) might in fact prevail in this sphere or that, but only on the basis that all paid tribute to the *shari'a* as uniquely authoritative.

Modern Changes.—The situation was radically changed as a result of the *Tanzimat* legislation in the Ottoman empire. In 1850 a commercial code was promulgated and in 1858 a penal code, both based on European models; and frankly secular (*Nizami*) courts were set up to apply these codes under modern forms of procedure. Much the same happened in Egypt, which attained juridical independence under the khedive Ismail. Meanwhile the *shari'a* courts continued to apply the old law in the old way, but were confined in their jurisdiction to the family law of Muslim litigants. And the resulting dichotomy in both the courts and law was only partially bridged by the fact that in the Ottoman empire the codified law of obligations applied by the secular courts was based not on European law but on precepts derived from the *shari'a*.

It was not till 1915 that the reformers ventured to tackle the family law of Islam, but by then the miserable position of Muslim wives, bound by the dominant Hanafi opinion, made reform inevitable. A tentative beginning in 1915 led to the Ottoman Law of Family Rights (1917) and to subsequent reforms in most of the Arab countries. These reforms differ from the earlier ones in that they do not replace the *shari'a* by an open adoption of largely western law but contrive, by a variety of ingenious devices, to effect changes in the "immutable" *shari'a* itself as applied in the courts. And the most widely used of these devices is that of denying that the judge should be bound, in every respect, by the dominant opinion of his particular school, and of asserting instead that the legislature may specify which of the reputable dicta of the past—supplied in such abundance by the different schools and even individual jurists—should be applied today, in this matter or that, in the public interest. As a consequence the family law of Islam is now largely codified, in most Arab countries, on the basis of an eclectic choice between all the available dicta.

Then, just before the middle of the 20th century, a tendency appeared (in Egypt, Syria, Libya and Iraq) to adopt new civil codes which, although predominantly western in inspiration, incorporated as much as they could of precepts derived from, or at least consonant with, the *shari'a*. Thus the clear-cut dichotomy in both courts and law that prevailed in most of these countries from the 19th century onward began to break down. For the *shari'a* law, instead of being ascertainable only from a study of numerous medieval texts, has largely been reduced to statute law—which can easily be applied by judges trained in modern law schools and which is leavened, to some degree, by modern concepts—while the "foreign" law is being given a somewhat more indigenous appearance. It is scarcely surprising, therefore, that modern, nationalist governments (*e.g.*, in Egypt and Tunisia) are tending to abolish the old communal courts and to unify the judicature.

Such, then, is the position in the more progressive Arab countries in the early 1960s. Throughout most of the Arabian peninsula, on the other hand, the *shari'a* still reigns supreme. Only in Turkey, at the other extreme, has the *shari'a* been completely displaced before the courts since 1926—even in the sphere of family law—in favour of codes adopted wholesale from the west; but even in Turkey the *shari'a* is widely (if unofficially) followed in practice in the villages of Anatolia. (*See* also the administration and social conditions sections of the articles on individual Muslim countries.)

ISLAMISM: *see* PAN-ISLAMISM.

ISLAND, any area of land smaller than a continent and entirely surrounded by water. Islands may occur in oceans, seas, lakes or rivers. A group of islands is called an archipelago.

Islands may be classified as either continental or oceanic. Oceanic islands are those which rise to the surface from the floors of the ocean basins. Continental islands are simply unsubmerged parts of the continental shelf (*q.v.*) that are entirely surrounded by water. Many of the larger islands of the world are of the continental type. Greenland (840,000 sq.mi.), the largest island, is composed of the same materials as the adjacent North American continent, from which it is separated by a shallow and narrow sea. Likewise the world's second largest island, New Guinea (319,000 sq.mi.), is part of the Australian continental platform and is separated from it only by the very shallow and narrow Torres strait. A slight warping of the sea bottom in the vicinity of Torres strait would be sufficient to join New Guinea to Australia; conversely, a slight rise in sea level may submerge a hilly coast and leave the hilltops remaining as small islands just off shore (examples being those off the coast near Boston, Mass., and the islands off the Maine coast).

The islands which rise from the floors of the ocean basins are volcanic. Lava accumulates to enormous thickness until it finally protrudes above the ocean surface. The piles of lava which form Hawaii rise to as high as 32,000 ft. above the ocean floor.

Many of the world's archipelagoes are arranged in island arcs, and they constitute some of the most active volcanic and earthquake areas of the world. Examples are the Leeward and Windward islands at the eastern end of the Caribbean, the Aleutians, the Japanese archipelago and the Philippines. Physical geographers believe that these are the areas of continental growth.

Island life exhibits features of special interest. The sea is a barrier to some forms of life but acts as a carrier of others, which, once established in their new home, frequently develop new features in their isolated surroundings. A long-established sea barrier results in marked differences between the animal life and vegetation even of adjacent islands, and from these differences may be deduced the origin of an island. Further, any detailed map of the biological regions of the globe illustrates the importance of islands in the determination of the boundaries of animal-life and vegetational types. For example, to the west of a line (Wallace's line) running between Bali and Lombok and between Borneo and Celebes the islands are biologically Asian, but to the east of the line, notwithstanding the narrowness of the Lombok strait, the vegetation and animal life are Australian. Oceanic islands are usually colonized by only a few animal forms, chiefly sea birds and insects. They are often clothed with abundant vegetation, the seeds of which have been carried by air and water currents, birds, etc., but the variety of plants is by no means so great as that on the mainland. (W. C. C.)

ISLAY is the southernmost island of the Inner Hebrides, Argyll, Scot., 16 mi. W. of Kintyre and ¾ mi. S.W. of Jura, from which it is separated by the Sound of Islay. Pop. (1961) 3,866. Its maximum breadth is 15 mi. and the maximum length 25 mi. The sea lochs Gruinart and Indaal cut into it so deeply as almost to convert the western portion, the Rhinns district, into a separate island. It is rich and productive and has been called the "Queen of the Hebrides." The surface generally is regular, the highest summit being Beinn Bheigeir (1,609 ft.), but the shore is rugged. There are fresh-water lochs and rivers, which provide good trout and salmon fishing. Islay was the ancient seat of the "lord of the Isles," the first to adopt that title being John Macdonald of Isle of Islay (d. *c.* 1386); but the Macdonalds were ultimately ousted by their rivals, the Campbells, about 1616. Islay house, ancient seat of the Campbells of Islay, is at the head of Loch Indaal. Much business is done in stock raising, dairy farming and cheese-making; oats, potatoes and various green crops are raised. The chief difficulty in the way of reclamation is the great area of peat (60 sq.mi.). The island has several distilleries, producing large quantities of whisky. Local limestone is used extensively as fertilizer, but deposits of lead, iron, slate and marble are no longer worked. Bowmore is the chief town and administrative centre, and Port Ellen, the principal port, is a seaside and golfing resort. The U.S. troops and seamen who were lost in the "Tuscania" and "Otranto" in 1918 are buried on the island, and there is a memorial tower on the Mull of Oa, 8 mi. from Port Ellen. Port Askaig is the ferry station for Feolin on Jura. There are five lighthouses on the island. In addition to a regular steamer service there is also a plane service connecting Glenegedale airport, Islay, with Renfrew (Glasgow airport).

ISLES OF THE BLEST (FORTUNATE ISLANDS), placed, in Greek mythology, in the western ocean and peopled not by the dead but by mortals upon whom the gods had conferred immortality. Like the Phaeacian land in Homer or the Celtic Avalon and St. Brendan's Island, the Isles of the Blest have perpetual summer and abundance. No reference is made to the isles themselves by Homer, who, in the *Odyssey*, speaks instead of the Elysian Plain; but they are mentioned by Hesiod and Pindar. By medieval map makers, Madeira and the Canaries are sometimes named *Fortunatae insulae*. *See* ATLANTIS; ELYSIUM.

ISLINGTON, a metropolitan borough of London, Eng., which under the London Government Act, 1963, was to be amalgamated on April 11, 1965, with Finsbury to form a new London borough (*see* LONDON). Islington is bounded east by Stoke Newington and Hackney, south by Shoreditch and Finsbury and west by St. Pancras. Pop. (1961) 228,833. Area 4.8 sq.mi. It includes Holloway, Highbury, Barnsbury and Canonbury, whose names preserve those of ancient manors. In Canonbury, which belonged in the 13th century to the priory of St. Bartholomew in Smithfield, parts of the old manor house, including Canonbury tower, remain. The fields and places of entertainment in "merrie Islington" were popular with Londoners in the 17th century and later. At Copenhagen Fields a great meeting of labourers was held in 1834 and to this site the Metropolitan Cattle market was moved from Smithfield in 1855. The market square became the site of the Caledonian market, a large twice-weekly general market with more than 2,000 stall holders which existed until the outbreak of World War II; in 1951 this market moved to Bermondsey. The Royal Agricultural hall, Archway hospital, Pentonville and Holloway prisons and the Arsenal football stadium are in Islington. New River Head is the termination of the artificial channel by which Sir Hugh Myddelton (1561–1631) brought water to London from the upper Lea valley. Islington is mainly residential, but light industry has been developed. Islington returns three members to parliament.

ISMAIL I (1487–1524), shah of Iran from 1501 to 1524 and founder of the Safawid dynasty, was born on July 17, 1487, probably at Ardabil. Through his father, Sheikh Haidar, he was descended from the greatly revered Sheikh Safi al-Din of Ardabil, who had founded an order of Sufis there in the early 14th century. Sheikh Haidar, who was a fanatical Shi'ite, fell in battle against the Sunnis of Shirvan when Ismail was only one year old. After many hazardous adventures, in the course of which his two elder brothers perished, Ismail succeeded, with the support of seven Turkmen Shi'ite tribes, in establishing his authority in northwestern Iran and was crowned in Tabriz in July 1501. In a series of battles he gained control over the greater part of Iran in the next few years. He thereupon attacked the Sunni Uzbeks who had occupied part of northeastern Iran and defeated them near Merv in 1510. Although many of his subjects had at the outset been Sunnis, he converted the majority to Shi'ism, which became the state religion and served to bind the nation together.

When the Ottoman Turkish sultan Selim I savagely suppressed a revolt of his Shi'ite subjects in Anatolia and persecuted the survivors, Ismail marched to their assistance but his forces, which consisted only of tribal levies, were severely defeated in a hard-fought battle at Chaldiran in northwestern Iran (1514). Against Selim's well-trained janizaries and artillery Ismail had neither regular troops nor cannon. Selim marched on and occupied Tabriz, but a mutiny of his troops compelled him to withdraw to Turkey. Ismail recovered from this reverse sufficiently to prevent any further inroads by either Turks or Uzbeks, and when he died, at Ardabil in 1524, he left Iran a united nation strong enough to protect itself. His dynasty endured till 1736.

The Venetian traveler Giovanni Angiolello, who was in Persia in 1510, described Shah Ismail as "fair, handsome and very pleasing; not very tall, but of a light and well-framed figure. . . . He is as brave as a gamecock, and stronger than any of his lords."

See Ghulam Sarwar, *History of Shah Ismail Safawi* (1939).

(L. Lo.)

ISMAIL HADJI MAULVI-MOHAMMED (1781–1831), Indian Muslim reformer, was born at Pholah near Delhi. In co-operation with Syed Ahmed he attempted to free Indian Islam from the influence of the native early Indian faiths. The two men traveled extensively for many years and visited Mecca. In the Wahhabite movement they found much that was akin to their own views and on returning to India preached the new doctrine of a pure Islam. The official Muslim leaders objected, and the dispute led to the reformers' being interdicted by the British government in 1827. The party then moved to Punjab where they made Peshawar the capital of the theocratic community which they wished to establish (1829). Ismail Hadji fell in battle against the Sikhs amid the Pakhli mountains (1831). Some of his adherents are still found in the mountains of the northwest frontier.

Ismail's book *Taqouaiyat et Iman* was published in Hindustani and translated in the *Journal of the Royal Asiatic Society*, xiii, 1852.

ISMAILIA (AL ISMA'ILIYAH), a city and governorate of Egypt, located at the Isthmus of Suez where the Sweet Water canal from the Nile meets the Suez canal at Lake Timsah. It lies on the northwestern shore of the lake, a salt lagoon through which the Suez canal passes, and is 93 mi. N.E. of Cairo by rail, 48 mi. from Port Said and 52 mi. from Port Tewfik (Bur Tawfiq). Pop. (1957) 94,572. The town was established in 1863 by the

former Suez Canal company and named after the khedive Ismail. It shows French influence, being laid out on a gridiron plan, with squares, gardens and tree-lined boulevards. The company built for its employees houses, schools and a 200-bed hospital, and provided recreational facilities. The central position of the town favoured the establishment there of the Central Movement office, which regulates the daily movement of shipping in the canal. Ismailia was the scene of the first scientific attack upon malaria, which later practically disappeared. The town became a headquarters for the Allied forces during 1916 and has retained its military connections. On the other side of the lake are the so-called quarries of Hyenas, from which building material for the town was obtained.

Ismailia governorate (area 187 sq.mi.) was formed in implementation of the law of local government, 1960. It comprises the city of Ismailia with the addition of the areas Tel el Kebir (At Tall al Kabir), Al Qassasin al Jadidah and Al Qassasin al Qadimah. Pop. (1961 est.) 276,000. (A. B. M.)

ISMA'ILISM, a religious and political movement in Islam, being a branch of the Shi'ah movement and deriving its name from Isma'il (mid-8th century), son of the imam Ja'far al-Sadiq (*see* SHI'ISM). Isma'il's followers formed extremist sects during his lifetime, but the movement which gave fame to the Isma'ili name was organized in the middle of the 9th century, when missionaries went out to different parts of the Islamic world preaching the return of Mohammed, Isma'il's son (dead long since), as the expected Mahdi ("Messiah"). The best-known branch of the movement in its earlier period was that of the Karmatians (*q.v.*). In the meantime, however, a schism occurred when the leader of the movement declared himself imam and was acknowledged as such by the greater part of the movement—though some continued to hold fast to the figure of the expected Mahdi. 'Ubaydullah, the first of the Fatimid imams, established himself in Ifriqiya (mod. Tunisia) in 909, claiming descent from Mohammed, son of Isma'il (and through him from Fatima, daughter of the Prophet, whence the name of the dynasty), through a line of "hidden imams." His opponents, however, did not admit this claim and alleged that he was a descendant of a certain 'Abd Allah ibn Maymun al-Qaddah (an early Shi'ite notable), to whom, in addition, was ascribed a conspiracy aiming at the destruction of Islam—this latter trait being a manifestly false invention.

The Fatimids conquered Egypt in 969, and for two centuries their empire was a brilliant centre of Islamic civilization (*see* EGYPT: *History;* FATIMIDS). Though they did not succeed in converting the bulk of the population in their dominions to their creed, they did rally round themselves a widespread movement which had followers all over the Islamic world and which possessed a closely knit organization. The main doctrine of the sect concerned the allegorical interpretation of the Koran and of religious practices in which they tended to discover allusions to the imams and the organization of their movement. They also adopted some of the teaching of Neoplatonic philosophy, which had at that time great currency among Muslim intellectuals. The "Epistles of the Sincere Brethren," a philosophical encyclopaedia based on Neoplatonism, was composed by the members of a circle connected with Isma'ilism.

During the reign of al-Hakim (996–1021) the Druzes, who considered the imams as incarnations of the godhead (al-Hakim being the last of these), separated from the main body of Isma'ilism (*see* DRUZE).

A fatal schism split the movement over the successor of the caliph al-Mustansir (d. 1094). In Egypt the throne was occupied by his son al-Musta'li, but the Isma'ilis of Persia and Syria upheld the claims of his older son, Nizar (who died in prison in Cairo); henceforth there were two branches, the Musta'lis and the Nizaris. In Egypt Isma'ilism came to an end when the last Fatimid caliph was deposed by Saladin in 1171, but Musta'lian Isma'ilism survived in Yemen. There the sectarians (who had not acknowledged the last four Fatimid caliphs—those after al-Amir, al-Musta'li's son—as legitimate imams) believed that al-Amir's infant son al-Tayyib (who had presumably been done away with on his father's death in 1130) was alive and would return in the fullness of time; thus this branch has no line of imams after al-Tayyib and is governed by the chief missionary (*da'i*). Musta'lian Isma'ilism was carried from Yemen to India, and in the 16th century the *da'i* moved to that country; he resides in Surat, in Gujarat district. His followers in India are usually known as Bohras ("merchants").

The Nizaris, led by Hasan ibn al-Sabbah, obtained control of a number of fortresses in Persia and Syria, the chief of them being Alamut (1090), from which Hasan and his successors commanded the sect, which was organized as an order based on territorial possessions. They employed as a means of terror the method of assassinating prominent personalities, whence their nickname hashishi ("hashish-eater") passed into European languages in the meaning of "assassin" (*see* also ASSASSIN). Hasan's fourth successor, also called Hasan, declared himself a descendant of the imam Nizar and proclaimed the arrival of the eschatological period of "resurrection"; he and his successors were considered by their followers as manifestations of the deity. When the political power of the Assassins was broken in Persia by the Mongols (who captured Alamut in 1256) and in Syria by the Mamelukes, the sect survived, led by their imams, who were descendants of the rulers of Alamut. From the 14th century two rival lines existed. In the 16th century, Tahir Shah—of the minor line—emigrated to India, where his descendants, who commanded the allegiance of the Isma'ilis of Syria, can be traced for another two centuries. The imams of the major line lived in various parts of Persia, until in 1840 the imam (best known by his title of the Aga Khan; *q.v.*) went to India. He and his descendants, also known as the Aga Khans, have a numerous following (estimated at several millions) in India and Pakistan, the regions of the Pamir and the upper Amu-Darya, Iran, Africa (consisting of Indian emigrants) and Syria (where the sectarians rallied to their leadership at the end of the 19th century).

ISMAIL PASHA (1830–1895), hereditary viceroy of Egypt under Turkish suzerainty, was the second son of the vali Ibrahim Pasha (*q.v.*). Born in Cairo on Dec. 31, 1830, he was educated in Paris and on reaching manhood undertook various diplomatic missions in Europe for the viceroy Mohammed Said Pasha, whom he succeeded in 1863. Ambitious to increase his prestige he obtained from the Ottoman sultan in 1867 the hereditary title of khedive, an honorific borne by his successors until 1914.

Beyond his frontiers Ismail pursued an expansionist policy. In 1865 he negotiated with the sultan the cession to Egypt of the ports of Sawakin (Sudan) and Massawa (Eritrea). He modernized the Egyptian army with Remington rifles and Krupp artillery and enlisted a corps of American officers who established a general staff, explored the Sudan and in 1877 prepared a notable map of Africa. In 1870–75 he extended Egyptian authority down the Red sea coast, planting garrisons at Harar and Berbera, but his attempt to occupy Kismayu in 1875 was prevented by Britain. In 1869 he commissioned Sir Samuel Baker to annex parts of Uganda; in 1874 Darfur was added to the Egyptian dominions. Ismail's territorial ambitions were thwarted in Equatoria where Baker's successor, Col. (later Gen.) C. G. Gordon, withdrew the Egyptian outposts from most of Uganda in 1876 and in Ethiopia where two Egyptian armies were disastrously defeated in 1875–76.

Ismail's westernizing domestic policy greatly benefited Egypt. Primary education was expanded in the provinces. The legal disabilities suffered by Egyptians under the capitulations were lessened by the institution in 1876 of mixed courts. An astute landlord of his vast estates and an enthusiastic town planner, he created the modern Cairo and in 1869 granted Alexandria a municipality. The summoning of a legislative assembly in 1867 marked the first approach toward constitutional government. His most spectacular achievements lay in the development of communications. He extended the railways, nationalized the postal service in 1865 and in the Sudan introduced telegraphs in 1866 and a short railway in 1875. In 1869 he presided over the opening of the Suez canal with lavish ceremonies.

His projects were often brilliantly conceived but they were compromised by his financial prodigality. By 1876 the Egyptian public debt exceeded £100,000,000. Pressed by Ismail's creditors the powers intervened and set up a dual control with a commission of the public debt. Ismail's resistance to the resulting encroachments upon his independence, culminating in his dismissal of the European commissioners, led to his deposition by the sultan at the instance of the powers on June 26, 1879.

Ismail died in exile at Istanbul on March 21, 1895. *See* also EGYPT: *History*.

See P. Crabitès, *Ismail, the Maligned Khedive* (1933); G. Douin, *Histoire du règne du Khédive Ismail*, 3 vol. (1933–41; unfinished). (R. L. HI.)

ISMAY, HASTINGS LIONEL ISMAY, 1ST BARON (1887–), British soldier who served in World War II as chief of staff to the minister of defense, was born at Naini Tal, India, on June 21, 1887, the younger son of Sir Stanley Ismay. Educated at Charterhouse and at Sandhurst, he was commissioned in 1905 and joined the 21st cavalry (Frontier force), Indian army, in 1907. Service on the North-West Frontier of India (1908) and in Somaliland (1914–20) was followed by appointments as assistant secretary (1926–30) and secretary (1938–40) of the Committee of Imperial Defense, and as chief of staff to the minister of defense (1940–46). He was promoted general in 1944 and created 1st baron in 1947.

In 1947 he returned to India as chief of staff to the last viceroy, Earl Mountbatten, and four years later became secretary of state for commonwealth relations (1951–52). Lord Ismay became secretary-general of the North Atlantic Treaty organization in 1952 and on vacating that appointment in 1957 retired from public life. His *Memoirs* were published in 1960. (C. N. B.)

ISMAY, THOMAS HENRY (1837–1899), English shipowner and founder of the Oceanic Steam Navigation company, which became famous as the White Star line, was born at Maryport, Cumberland, on Jan. 7, 1837. In 1867 he took over the White Star line of Australian clippers and in 1869 established, with William Imrie, the Oceanic Steam Navigation company. The firm having determined to enter the Atlantic trade, the first "Oceanic" (3,707 tons) was ordered from Harland and Wolff, of Belfast, Ire. The launching in 1870 marked a turning point in the development of the North Atlantic passenger liner; among the innovations introduced was the locating of passenger accommodations amidships. In 1892 Ismay retired from partnership in the firm of Ismay, Imrie and company, though he retained the chairmanship of the White Star line. He died near Birkenhead, Cheshire, on Nov. 23, 1899.

The White Star line continued until 1934, when it merged with the Cunard line to form Cunard White Star, Ltd. The assets of Cunard White Star were taken over by the Cunard Steam-Ship Co., Ltd. in 1950.

ISMET INÖNÜ: *see* INÖNÜ, ISMET.

ISNA (ESNA; ESNEH), a town of upper Egypt in Qina governorate lies on the west bank of the Nile, 36 mi. S. of Luxor. Pop. (1957) 22,128, mostly Copts. The town manufactures pottery and cottons and has large grain and livestock markets. Some trade is carried on with Kharga oasis (Al Wahat Al Kharijah) 110 mi. W.

Just below the town is the Isna barrage (1908), built to improve the irrigation of upper Egypt. The barrage, of granite and sandstone with 150 sluices, was reconstructed in 1948 and raises the upstream water level by 15 ft. (A. B. M.)

Isna takes its name from the ancient Egyptian Ta-Senet, but in Ptolemaic times it was called Latopolis, because the fish *Lates niloticus* was worshiped there. The ruins lie buried beneath the modern town, and only the pronaos of the temple has been cleared. Dedicated to Khnum, the ram-headed creator god, the temple took from about 180 B.C. to A.D. 250 to build. It is in Ptolemaic style, though the decoration is largely Roman. Always a Coptic centre, there is a Christian church in the desert, within ½ mi. of the modern town. The Coptic population suffered severely under Diocletian's persecution of A.D. 303. (M. V. S.-W.)

ISNEG (APAYAO), a Malayan-type people living in the mountains of northwest Luzon, Philippines. Isneg is the usual anthropological name, while Apayao is the district name and also that of the subprovince of Mountain province within which nearly all of them live. The Isneg numbered approximately 11,500 in the 1960s. They are short in stature and rather darkly pigmented, probably through minor mixture with Negrito groups adjacent to them. They have a distinctive language, with several dialect areas. The main body of Isneg lives on the Abulug or Apayao river system which drains most of their territory, but a group called the southern Isneg lives on the Matalag river system in the south of the subprovince. The Isneg economy is based on natural rainfall ("dry") cultivation of rice, corn and tropical roots in shifting gardens, supplemented by hunting, fishing, keeping livestock and trading tobacco and other products to the lowlands. Settlements are of hamlet size, scattered along the streams which drain the dense rain forests of the region. Each group of adjacent hamlets is crisscrossed by marriage and kinship ties. The region was noted for its head-hunting, with warrior bravery and head trophies the principal means by which males (if they survived) gained status, so that apart from a hamlet's immediate circle of friendly kinsmen all others tended to be enemies. The Isneg built substantial wood houses with high pitched roofs but also had huts in their rotating fields; they had distinctive dress and customs generally. Spanish missionaries worked up the rivers in the 17th and 18th centuries, but their converts were generally transferred to the lowlands; pacification was achieved by U.S.-Philippine constabulary forces in 1908–13.

Keesing, *Taming Philippine Headhunters* (1934); J. B. Vaughan, *Land and People of the Philippines* (1956); L. L. Wilson, *Apayao Life and Legends* (1947). (F. M. Kc.)

ISOBAR, a line on a map or thermodynamic chart, connecting points having the same pressure. Isobars for intervals of two to five millibars of pressure are important features of weather maps because of the relationship between pressure distribution, winds and weather. *See* METEOROLOGY. (H. R. B.)

ISOCRATES (436–338 B.C.), a famous writer and educationalist at Athens, who by the artistic form of his prose set a model which influenced many later writers. His father, Theodorus, was an Athenian citizen of the deme (township) Erchia; he owned a flute factory and was rich enough to perform expensive services to the state and to give his sons a good education. Isocrates' teachers are said to have included well-known sophists, but the details are uncertain. He must have been familiar with Socrates, although he does not appear to have been a member of the Socratic circle. Both sophistic and Socratic influences can be seen in his works. The family property was lost during the Peloponnesian War and, after the restoration of democracy in 403 B.C., Isocrates found it necessary to follow a profession. Physical infirmities prevented him from speaking in public and taking an active part in political life. For about ten years he wrote legal speeches for clients. It was an activity he despised and one to which he makes no allusion in his later works. About 392 B.C. he founded his famous school. It was highly successful and for over 50 years attracted pupils from all parts of the Greek world. He died soon after the defeat of Athens by Philip II of Macedonia at the battle of Chaeronea in 338 B.C.

Speeches.—Isocrates' extant works consist of 21 speeches (*logoi*) and nine letters. "Speech" is a convenient rendering of *logos*, but it is misleading. Only the six early forensic works are real speeches. It has been suggested that even these were rhetorical exercises, but most scholars believe that they were written by Isocrates, before he started his career as a teacher, for clients to deliver in the law courts. The rest are purely literary. Many by an artistic fiction are given the form of real speeches, but little attempt is made to keep up the illusion consistently. Some take the form of a hortatory address, others of a prose encomium. These literary speeches were presumably circulated as pamphlets among the Greek-speaking public. Isocrates seems also to have intended them to be recited by others to audiences. What are clearly instructions to reciters are to be found in the introductory part of the *Antidosis*. The literary speeches, the dating of which

can in most cases only be approximate, may be roughly divided into two groups according to their subject matter:

Political Speeches.—Panegyricus (*c.* 380 B.C.) and *Philippus* (346 B.C.) deal with Greek unity and war against Persia. *On the Peace* (*c.* 356 B.C.) and *Areopagiticus* (*c.* 355 B.C.) give advice on Athenian foreign and home policy, respectively. In *Plataicus* (*c.* 373 B.C.) a Platæan citizen urges the Athenians to restore Plataea after its destruction by Thebes. *Archidamus* (*c.* 366 B.C.) is supposedly delivered by Archidamus III of Sparta, who comments on conditions of peace offered by Thebes.

Speeches on Education, Ethics and Literary Criticism.—Isocrates' views on education are given mainly in *Against the Sophists* (*c.* 390 B.C.) and *Antidosis* (354–353 B.C.). *To Demonicus* (*c.* 370 B.C.?), regarded by some as spurious, contains moral precepts. *To Nicocles* and *Nicocles* (both *c.* 370 B.C.) outline the duties of a monarch and his subjects, respectively. *Busiris* (*c.* 390 B.C.), *Helen* (date uncertain, perhaps 390–380 B.C.) and *Evagoras* (*c.* 365 B.C.) are ostensibly encomiums, a genre of rhetorical literature then in vogue, but their main purpose is to advertise Isocrates' literary views. *Panathenaicus* (*c.* 339 B.C.), a long, rambling work of Isocrates' extreme old age, is partly an encomium of Athens, partly an exposition of his theories on writing and teaching.

Letters.—The letters, which are addressed to kings and rulers, serve the same purpose as the speeches: they advertise Isocrates' views on current affairs. They may have been actually sent to the individuals in question, but most of them at any rate were intended for a wider public. There seems to be little essential difference between the letters and the speeches except that the former are shorter and less elaborately composed. All were written in Isocrates' old age. Their authenticity has often been questioned, but most of them at least are now considered genuine.

Political Views.—The dominant theme in Isocrates' political writings is the policy of unifying Greece against Asia. A war against Persia, he claimed, would give the Greeks a common cause and put an end to their disastrous internal dissensions. In his most famous work, the *Panegyricus*, he urged Athens and Sparta to forget their quarrels and jointly lead Greece against the common enemy. His pleading was ineffectual, and in his subsequent efforts to find a champion of the Greek cause he turned first to Dionysius the Elder of Syracuse, then to Archidamus III of Sparta and finally to Philip II of Macedonia. From his third letter written shortly before his death it appears that even after the battle of Chaeronea he continued to hope that Philip would lead a united Greece against Persia. There seems no reason to doubt the authenticity of this letter. Two works concern Athenian politics. In the speech *On the Peace* Isocrates urged Athens to abandon its imperialistic ambitions and to recognize the right of Greek states to independence. In the *Areopagiticus* he deplored the degenerate Athenian democracy of his own day and advocated a return to the restricted democracy of Solon and Cleisthenes. His political writing had little influence on the conduct of affairs; he himself complains bitterly that the Athenians preferred to listen to the platform oratory of the active politicians.

Educational System.—Isocrates' educational writings are interesting and revealing. *Against the Sophists* was written at the beginning of his teaching career. Only the first part, in which he disparages other intellectual and educational systems by comparing them with his own, is extant. His own views are more fully expressed in the *Antidosis*, written, according to his own statement, when he was 82 years old. He dissociated himself from contemporary rhetoricians whose methods, he claimed, had no educational value. Their purpose was a purely practical one; they concentrated on legal oratory, which Isocrates despised, and treated rhetoric as a technique consisting of rules and precepts which could be imparted by a competent teacher to any diligent student. His own system, which he preferred to call "philosophy," was far broader and more humane. He held that speech composition should be regarded as a creative process allowing full scope for individual talent.

On the details of his educational methods there is little information, but an essential part must have been the composition of speeches modeled on his own. He insisted that students must avoid narrow, petty or specialized themes and choose those of universal interest and importance. These must be expressed in a pleasing form which had attractions analogous to those of poetry. For mathematics and the speculative sciences he had little regard and he derided the conflicting results produced by the researches of the scientists and philosophers. Scientific knowledge (*episteme*) he contended was beyond the powers of human knowledge; the most man could do was to learn by practical experience. He preached a high standard of morality, but morality he conceived in terms of an enlightened self-interest (*pleonexia*); those gained the true advantage who were righteous toward gods and men, in public and private life.

His pupils included sons of illustrious Greek families, men who became prominent in public life as orators and statesmen, and well-known historians, such as Ephorus and Theopompus. His success was remarkable, but he had many critics. Plato's Academy was founded shortly after Isocrates' school, and rivalry between the two establishments was inevitable. Covert attacks on Plato are found in Isocrates' works, particularly in the introductory part of the *Helen*. Plato's commentary on Isocrates comes mainly in the *Phaedrus*, but the allusions are veiled and scholars differ in interpreting them. Their general tenor, however, seems clear. Plato was willing to allow that artistically and morally Isocrates' humanism was on a higher level than the mere technique of other rhetoricians, but he considered his system unworthy of serious consideration because it was not founded on scientific method.

Conclusion.—Isocrates was not an original thinker. Nearly all his views, whether on politics or education, are adaptations of those already expressed by others. His greatest achievement was the artistic form he gave to his writings. The speeches written before his powers declined show infinite care both in structure and style. His method was to prepare a skeleton outline and build up the speech section by section, taking pains to avoid an abrupt transition from one subject to another. His style is an elaborate instrument of expression. Avoidance of hiatus and harsh collocations of syllables produces a smooth, harmonious flow of language. This is enhanced by a subtle use of rhythm which defies analysis. It suggests a fondness for certain clausulae but never so obtrusively as to reveal a fixed metrical scheme. He avoided the more extravagant ornaments which gave Gorgias' prose a meretricious appeal, *e.g.*, unusual words, startling metaphors, jingling assonance, but in building up his periods he indulged freely in balanced clauses and antithesis. With much reading the balanced periods become monotonous. He himself seems to have been aware of this. In his advice to reciters of his works he warns them to read only so much as will not weary listeners. His influence on subsequent prose writers, notably Cicero, was considerable.

ISOGAMY, a term applied in biology to conditions in which the sex cells or gametes are alike, in contradistinction to heterogamy (*q.v.*) or anisogamy, in which the gametes are differentiated into male elements (spermatozoa or microgametes) and female elements (ova or macrogametes). Isogamy occurs in some of the lower algae and in certain Protozoa, but it seems that in most cases, if not in all, the gametes behave differently so that they are functionally anisogamous. *See* ALGAE; PROTOZOA; REPRODUCTION.

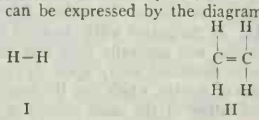
ISOMERISM. In the period when chemical analysis was first introduced, the belief was generally held that the properties of each pure substance depended solely upon its chemical composition. Two samples of matter, which had the same properties, and so were composed either of the same substance or else of mix-

tures of the same substances in the same proportions, were therefore supposed to be identical in composition. Conversely, any difference that could be detected in the properties of two substances under the same conditions was held to be due to some difference in composition.

The fundamental postulate that the properties of a pure substance are uniquely determined by its chemical composition was subsequently found, however, to be subject to certain well-defined types of exceptions. These may be classified under the three headings as: (1) polymorphism, where the difference of properties exists only in the solid state and is considered therefore to be caused by a different arrangement of identical molecules or ions in a crystal; (2) polymerism, where the molecules are of identical percentage composition but of different molecular weight; and (3) isomerism, where the molecules are of identical percentage composition and molecular weight but are considered to differ in their internal structure or configuration. (It should be noted that modern usage has somewhat altered the historical definition of the word "polymerism," given here. *See* POLYMERIZATION. The slight change in meaning thus introduced is, however, of no importance to the present article.) Although these three types of exception were grouped together at one time under the general term "isomerism," the distinctions outlined above are now commonly made, and the word "isomerism" is now restricted to the type (3). The present article will deal only with isomerism in this restricted sense. (For discussions of polymorphism, *see* CHEMISTRY: *Physical Chemistry;* for one of polymerism, *see* POLYMERIZATION.)

Structural Isomerism.—The field of isomerism is subdivided into two main divisions, structural isomerism and stereoisomerism. Two (or more) substances are said to be structural isomers of each other, or to be structurally isomeric, if they have the same chemical composition and molecular weight, but differ in structure; on the other hand, they are said to be stereoisomers of each other, or to be stereoisomeric, if they have the same composition, molecular weight, and structure, but differ in configuration. In order that the significance of this distinction may be made clear, the technical meanings assigned by chemists to the words "structure" and "configuration" must be discussed. The present section, however, will deal only with the concept of structure, since that of configuration is not required for an understanding of structural isomerism. (For the definition of configuration *see* the section below on *Stereoisomerism* and the more detailed article on STEREOCHEMISTRY.)

The structure of a substance (or, more precisely, of its molecules) is given by a detailed statement of the way in which each atom is linked by valence bonds to each of the other atoms of the molecule (*see* VALENCE). This statement may take any of several equivalent forms. One such form is based upon the use of purely verbal descriptions. Thus, the structure of the hydrogen molecule, H_2, may be expressed by the statement that the two univalent hydrogen atoms are joined to each other by a single covalent bond; the structure of the ethylene molecule, C_2H_4, may be expressed by the statement that each of the two quadrivalent carbon atoms is joined to the other by two covalent bonds, and also to two univalent hydrogen atoms by single covalent bonds; and so on. A verbal scheme of this sort, however, becomes too unwieldy for the description of the structure of a molecule of any complexity, and so a second, much more convenient, method of representation has been generally adopted. When this method is employed, any given structure is represented by a diagram, in which each atom is symbolized by the usual chemical symbol of the element in question, and in which each covalent bond is symbolized by a (usually straight) line drawn between the letters representing the appropriate atoms. Thus, the structures of the molecules of hydrogen and of ethylene, which were described verbally above, can be expressed by the diagrams I and II, respectively. Such symbols as these are usually referred to as the structures of the respective substances, although, in a strict sense, they are merely graphical representations of the structures of the corresponding molecules. (The more modern electronic structures, in which each line is replaced by a pair of dots, differ from the foregoing in no respect which is important to the present discussion. Such modes of description will therefore be ignored here. However, *see* VALENCE.)



I II

In the graphical scheme outlined above, no symbol for the representation of an ionic bond was mentioned. Actually, at the present time, the following convention seems to be generally adopted. If two or more parts of a molecule are not joined to each other in any way by covalent bonds, but instead are held together by only ionic linkages, then each of the parts (*i.e.*, ions) is represented separately by its corresponding symbol, and the various symbols are merely placed close together. The existence of the electrostatic attractive forces is shown by the presence of appropriate plus or minus signs, as superscripts, to indicate the charges on the ions. Thus, the structure III can be written for the molecule of sodium chloride, which exists in the gaseous but not in the solid state or in aqueous solution (*see* MOLECULE). If any ion contains more than a very few atoms, its structure is often surrounded by square brackets for the sake of clarity. Thus, the structure of the molecule of ammonium chloride (if such a molecule be capable of existence at all, *see* MOLECULE) may be given as IV.

III IV

Significance of Structural Diagrams.—As has been explained, the function of a structure is to specify the pairs of atoms which are joined by valence bonds, and to state the number and type of the bonds which connect each of these pairs. Consequently, the exact geometrical properties of any diagram that may be written on paper are of no structural significance. In particular, the lengths of the lines which represent the covalent bonds, the angles between pairs of lines, and the relative positions on the page of the letters which represent the atoms must be ignored. The diagrams Ia, Ib and Ic, for example, represent exactly the same structure that I does; in the same manner, IIa, IIb and IIc are to be considered identical with II; and IVa and IVb are to be considered identical with IV. This fact is extremely important, since it greatly restricts the number of nonequivalent structures that can be written for a molecule containing a specified number of atoms of specified kinds. It must be constantly borne in mind, in fact, that diagrams which look entirely different superficially may actually represent the same structure. (The situation may be described in mathematical language by the statement that the chemical structures, as defined here, are topological diagrams and have no nontopological significance. *See* TOPOLOGY, GENERAL.)

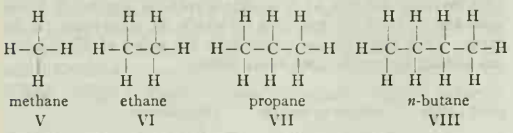
IVa IVb

The Number of Isomers.—A fundamental postulate of the

structural theory of chemistry is that two molecules which differ in structure must correspond to different substances with different chemical and physical properties. A corollary of this fundamental postulate is that the number of theoretically possible structural isomers which have a given molecular formula (*i.e.*, which have a given chemical composition and molecular weight, *see* MOLECULE) must be equal to the number of nonequivalent structures permitted by the rules of valence. The general procedure of calculating isomer numbers can be illustrated with a few examples. For the molecular formula CH_4, only the single structure V can be drawn if carbon and hydrogen are, as usual, considered to be quadrivalent and univalent, respectively. Similarly, for the formulae C_2H_6 and C_3H_8, only the single structures VI and VII, respectively, are possible. In agreement with expectation, only a single substance exists for each of these formulae.

On the other hand, for the formula C_4H_{10}, the two nonequivalent structures VIII and IX can be drawn, and, accordingly, two isomeric substances exist; these are known as normal butane and isobutane, respectively. Moreover, for the molecular formula C_2H_4, only the single structure X is possible, but, for the formula C_3H_6, the two structures XI and XII, and, for the formula C_4H_8,

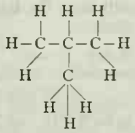


methane V

ethane VI

propane VII

n-butane VIII



isobutane IX

the five structures XIII–XVII, can be drawn. Again, the number of nonequivalent structures in each case is exactly equal to the number of existing structural isomers. This procedure, which can be extended in an obvious manner, and with uniformly satisfactory results, to all further types of molecular formula (however, *see* below), forms the basis of structural chemistry. Its success provides an important part of the experimental justification of the structural theory.

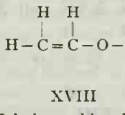
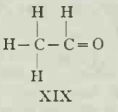
Anomalous Isomer Numbers.—The equality of the number of structures and of isomers corresponding to each molecular formula is subject to several different types of exceptions. The ideal situation would be that exactly one substance exist for each structure which can be drawn, and that, conversely, exactly one structure be associated with each substance which exists. Four types of exceptions to this ideal can be visualized, however, and examples of each type have been encountered: first, many structures which can be written correspond to no known substance at all; second, some structures must be associated with two or more different substances; third, some substances cannot be described by any structure of the usual type; and fourth, some apparently single substances behave as if they possess two or more distinct structures. If the prediction of the numbers of isomers is to be considered an essential function of the structural theory, these exceptions must be examined in order that their extent and significance may be evaluated.

(1) The fact that many structures can be written for which no corresponding substances are known is often merely the result of the fact that no chemist has as yet been sufficiently interested, or had sufficient time, to prepare samples of all the theoretically possible isomers. Even relatively simple molecular formulae may permit enormous numbers of structures; for example, it has been calculated that the formula $C_{20}H_{42}$ permits 366,319 structures and the formula $C_{40}H_{82}$ permits 62,491,178,805,831 of them! (Of course, such large numbers as especially the second of these are experimentally meaningless, since, even if a sample of each of the substances were available, there would be no way of proving that no two of them were identical. Only about 20 different substances that have the formula $C_{20}H_{42}$ and about 5 with the formula $C_{40}H_{82}$ are known.) The most complicated molecular formula for which all possible structural isomers have been prepared seems to be C_9H_{20}, with altogether 35 nonequivalent structures. For other formulae, incomplete sets of more than 100 known isomers are not uncommon, however. The essential point to be brought out here is that, in those cases in which a serious attempt has been made to prepare all the possible isomers, and in which the factors discussed below do not make success impossible, the theoretical isomer numbers have usually been confirmed experimentally.

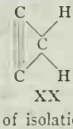
In some instances, however, attempts to prepare substances with certain structures have been unsuccessful in spite of repeated and varied attempts. For example, all attempts to prepare vinyl alcohol, XVIII, have led instead to the isomeric acetaldehyde XIX. Apparently, therefore, a substance with the structure



XVIII

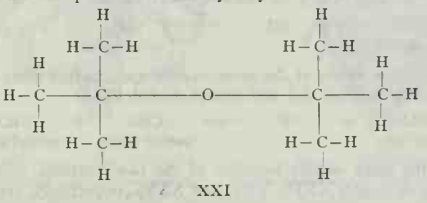


XIX



XX

XVIII is incapable of existence or, at any rate, of isolation, because it undergoes a rapid and spontaneous transformation into a different, isomeric substance. This phenomenon is discussed in the article TAUTOMERISM. In other instances, certain structures which can be written on paper correspond to molecules which would be so highly strained that they could not be expected to exist. A simple example of this is represented by the structure XX (of the unknown cyclopropyne); further examples are discussed in the article on STEREOCHEMISTRY: *Strain Theory*. Finally, certain structures correspond to substances for which no methods of preparation are known at present. In such instances, however, the substances might be capable of existence if only suitable methods of preparation could be devised. Thus, for about 50 years all attempts to make tertiary-butyl ether XXI led instead to



XXI

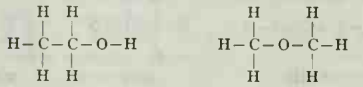
entirely different (and nonisomeric) substances, as a result of the failure of the chemical reactions to follow the desired courses; nevertheless, this substance was finally prepared in 1941. There is no obvious reason why the situation may not be similar with many other, as yet unknown, substances.

(2) The existence of structures which must be assigned to two or more different substances has made necessary a fundamental extension and broadening of the structural theory. The nature of the developments arising from this cause is discussed briefly in the section on *Stereoisomerism* below, and in greater detail in the article on STEREOCHEMISTRY.

(3) Some substances exist for which no structure of the usual type can be written. In nearly all instances, however, such substances have been brought successfully into the structural scheme by suitable extensions of the theory. For example, it is now recognized that carbon, although it is quadrivalent in most of its compounds, is occasionally trivalent, and that many other elements also have greater or less tendencies to display variable valence. A large number of substances, to which structures could not be assigned if each element were considered always to have the same valence, can therefore be taken care of without difficulty. These variations in valence are fairly well understood, so that chemists usually know in advance when they are to be expected (*see* FREE RADICALS). New types of linkage which were not envisaged originally, such as the so-called hydrogen bond (*see* VALENCE), have been discovered; these frequently make possible the assignment of definite structures to otherwise anomalous substances. Finally, the theory of resonance (*see* RESONANCE, THEORY OF) has served to clear up most of the remaining difficulties by introducing a more generalized concept of structure. Although many substances still exist to which no structures have as yet been definitely assigned, there are now no longer many which seem to lie completely outside the structural scheme. (However, *see* the boron hydrides discussed in the article on BORON.)

(4) The existence of apparently single substances which act as if they have two or more structures has given rise to the concept of tautomerism (*q.v.*).

Assignment of Structures to Isomers.—The structural theory would be of relatively little practical value if it permitted only the calculation of the number of isomers and not the assignment of a definite structure to each of the isomers in those instances in which more than one structure is possible. For the formula C_2H_6O, for example, the two structures XXII and XXIII



XXII

XXIII

can be drawn, and the two substances, ethyl alcohol and methyl ether, are known. It is gratifying that the number of structures is equal to the number of isomers, but the chemist would still like to know which structure is to be associated with each isomer. The experimental methods for the determination of structure are varied, and only a few of the salient features of some of the most important methods can be mentioned here.

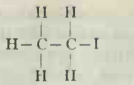
One of the most commonly applied methods for the determination of structure makes use of the chemical reactions of the substances in question. The assignment of structures to the isomeric ethyl alcohol and methyl ether, for example, can be made in the following way. The action of hydrogen iodide upon ethyl alcohol leads to ethyl iodide, C_2H_5I, and water, H_2O:

$$\underset{\text{ethyl alcohol}}{C_2H_6O} + HI \longrightarrow \underset{\text{ethyl iodide}}{C_2H_5I} + \underset{\text{water}}{H_2O}$$

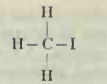
whereas the action of the same reagent upon methyl ether leads to methyl iodide, CH_3I, and methyl alcohol, CH_4O:

$$\underset{\text{methyl ether}}{C_2H_6O} + HI \longrightarrow \underset{\text{methyl iodide}}{CH_3I} + \underset{\text{methyl alcohol}}{CH_4O}$$

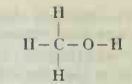
For the three organic products of the two reactions, only the single structures XXIV, XXV and XXVI, respectively, are possible.



ethyl iodide
XXIV



methyl iodide
XXV



methyl alcohol
XXVI

Comparison of these structures with XXII and XXIII shows that ethyl iodide XXIV is more closely related to XXII than to XXIII, and that methyl iodide XXV and methyl alcohol XXVI are more closely related to XXIII than to XXII. Consequently, the inference is drawn that ethyl alcohol has the structure XXII, since it leads to ethyl iodide, whereas methyl ether has the structure XXIII, since it leads to methyl iodide and methyl alcohol. In other words, the assumption is made that the courses of the chemical reactions are such that the least possible structural changes are produced. Although numerous exceptions to this rule of minimum structural change are now recognized (*see* MOLECULAR REARRANGEMENTS), it nevertheless forms at least part of the basis of most determinations of structure.

A second method for the determination of structure, which likewise involves the rule of minimum structural change, is based upon the study of the reactions by which the substances can be made. Thus, ethyl alcohol results from the action of dilute aqueous sodium hydroxide upon ethyl iodide:

$$\underset{\text{ethyl iodide}}{C_2H_5I} + \underset{\text{sodium hydroxide}}{NaOH} \longrightarrow \underset{\text{ethyl alcohol}}{C_2H_6O} + NaI$$

whereas methyl ether results from the action of concentrated sulfuric acid upon methyl alcohol:

$$\underset{\text{methyl alcohol}}{2CH_3O} + \underset{\text{sulfuric acid}}{H_2SO_4} \longrightarrow C_2H_6O + \underset{\text{methyl ether}}{H_2SO_4 \cdot H_2O}$$

Since the structures of ethyl iodide and of methyl alcohol have been shown (*see* above) to be XXIV and XXVI, respectively, the principle of minimum structural change again leads to the conclusion that ethyl alcohol must have the structure XXII and methyl ether must have the structure XXIII.

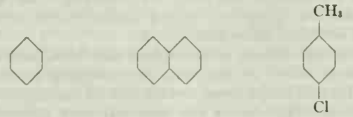
A third method, which makes no explicit use of the principle of minimum structural change, is based upon a comparison of the reactions of substances of unknown structure with those of other substances of known structure. Thus, ethyl alcohol and methyl alcohol resemble each other closely in their chemical properties, whereas methyl ether behaves quite differently toward most reagents. In particular, the two alcohols react with metallic sodium to give alkoxides, and with acid chlorides to give esters (*see* ALCOHOL), whereas methyl ether is inert toward each of these reagents (*see* ETHER). Consequently, the structures of ethyl alcohol and of methyl alcohol may be presumed to be similar to each other. Since that of methyl alcohol is necessarily XXVI, that of ethyl alcohol must therefore be XXII. Moreover, the remaining structure, XXIII, must belong to the remaining substance, methyl ether. The assignment of structures is thus the same as by the preceding methods.

Still a further procedure for the assignment of structures to isomers is somewhat more fundamental, but much less commonly used, than the ones just described. This method makes direct use of the numbers of isomeric derivatives that can be prepared from each of the isomeric substances in question. It has found its greatest use in the determination of the orientation of substituents in benzene.

Numerous further methods for the determination of structure are based upon the study of physical properties of various kinds. Mention may be made here of refractivities, molecular volumes, parachors, spectra, dipole moments, magnetic susceptibilities and nuclear magnetic resonance spectra. The diffraction of X-rays by crystals and that of electrons by gaseous substances has also been used in a number of instances for the establishment of structure. For further discussion of these methods, the reader is referred to the individual articles dealing with them.

Abbreviated Forms of Structures.—The detailed structures such as XXIV, XXV and XXVI (as well as most of the pre-

ceding ones) are too cumbersome for practical use. Consequently, abbreviated forms have been adopted for the purpose of convenience in writing and printing. Thus, XXIV becomes CH_3–CH_2I or, more simply still, C_2H_5I; XXV becomes CH_3I; and XXVI becomes CH_3OH. Even the rather complicated structure XXI can be expressed simply as $(CH_3)_3C$–O–$C(CH_3)_3$ or as $[(CH_3)_3C]_2O$. In the aromatic series, the structure of benzene



XXVII XXVIII XXIX

(*q.v.*) is written as a simple hexagon, as in XXVII, that of naphthalene (*q.v.*) is written as in XXVIII, and so on; hydrogen atoms attached directly to the carbon atoms of the aromatic rings are usually not indicated explicitly, although other, heavier atoms and groups are always specified, as in the symbol XXIX for *p*-chlorotoluene. (The phenyl and naphthyl radicals, however, are frequently indicated by their formulae, C_6H_5 and $C_{10}H_7$, respectively.) Benzene is also frequently represented by the so-called Kekulé structure XXX or by the conventionalized diagram XXXI. Other aromatic hydrocarbons can be depicted similarly.

XXX XXXI

Stereoisomerism.—When the structural theory was first developed, the natural assumption was made by most chemists that two substances with not only the same chemical composition and molecular weight but also the same structure would necessarily have to be identical. Nevertheless, examples were soon encountered in which this assumption appeared to be contrary to the facts. One of the first examples of this further type of isomerism to be carefully studied was that exhibited by tartaric and racemic acids. These substances must be assigned the same structure, HO_2C–CHOH–CHOH–CO_2H, and yet they differ in a number of their characteristic properties. In particular, they melt at different temperatures and have different densities, solubilities and crystalline forms. Moreover, tartaric acid is dextrorotatory (*i.e.*, its solutions rotate the plane of polarization of plane polarized light to the right, *see* STEREOCHEMISTRY), whereas racemic acid is optically inactive (*i.e.*, its solutions have no effect upon the plane of polarization). In a relatively short time, many further examples of the existence of a greater number of isomers than can be accounted for by the structural theory came to light. The extent to which these anomalous isomers differ in properties varies greatly from case to case. Sometimes, as with the dextro- and levorotatory lactic acids (*q.v.*), CH_3–CHOH–CO_2H, they are identical in nearly all their properties except in their effects upon polarized light and their reactions with other optically active substances; on the other hand, as with the above tartaric and racemic acids, they may differ noticeably in nearly all their properties; and finally, as with fumaric and maleic acids (*q.v.*), $HO_2C-CH=CH-CO_2H$, they may both be optically inactive.

The detailed discussion of this further type of isomerism is given in the article on STEREOCHEMISTRY. Here, only a few of the most important features will be pointed out. The first fact that has to be established is, of course, that the substances under discussion are actually isomers of one another, in the restricted sense in which the word is used in the present article, and not either polymorphic or polymeric forms. Polymorphism is easily shown not to explain the observations, since the differences in chemical and physical properties and in optical activity are found to persist in solution and in the liquid and gaseous states. Polymerism also is shown to be not involved, since the substances have the same molecular weight. The conclusion can be drawn therefore that the substances are truly isomeric, and that, although they possess the same structure, their individual molecules are not identical. Such isomers are said to be stereoisomers, and their molecules are said to differ in configuration.

The only suggestion regarding the significance of configuration which has received serious attention is that it refers to the arrangement of the atoms in space. That the difference between the dextro- and the levorotatory lactic acids might be explained in some such manner was proposed in 1873 by J. Wislicenus; more complete theories, upon which all subsequent work in stereochemistry has been based, were brought forward the following year by two independent investigators, J. H. van't Hoff and J. A. Le Bel. For a description of their ideas and a further discussion of stereoisomerism, the reader is referred to the article on STEREOCHEMISTRY. *See* also references under "Isomerism" in the Index.

(G. W. Wd.)

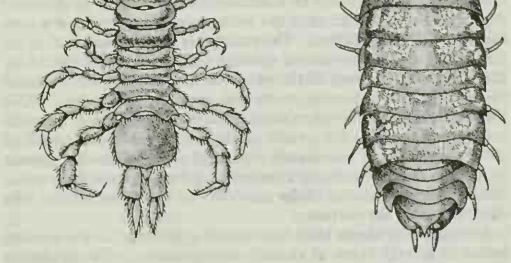
ISOPERIMETRY, a word originally used in geometry to refer to figures of equal perimeter; *e.g.*, a circle and an ellipse may have equal perimeters (circumferences) although not equal areas. One of the simplest of the problems arising in the study is to determine, from all plane figures having the same perimeter, the one that shall have the greatest area. This figure is the circle. Considered more generally, given any number of geometric figures, all defined in the same way, determine the form of the one possessing a maximum (or minimum) amount of a certain property; *e.g.*, of all the triangles having a given area (figures defined as plane, three-sided and of a given area), the one having the least perimeter is equilateral. (*See* CRITICAL POINTS.)

For the general definition and treatment consult works on the calculus of variations, where the theory is extended to include solid as well as plane figures.

ISOPODA, an order of crustaceans of the subclass Malacostraca (*q.v.*), including the familiar gribbles, wood lice (sow bugs) and slaters. Wood lice that curl up into a ball when disturbed are often called pill bugs. The body is characteristically dorsoventrally flattened, except in the suborder Phreatoicoidea, and ranges in size from $\frac{1}{36}$ of an inch (*Munna* species) to about 14 in. (*Bathyonomus*).

The majority of isopods are marine, but many, mostly of the suborder Asellota, live in fresh water. Most members of the suborder Oniscoidea are terrestrial scavengers, limited to damp surroundings (*see* WOOD LOUSE). A few isopods are cave dwellers; most of these are blind. The gribbles (*Limnoria* species) are important economically because of the great damage they do by burrowing in wooden structures in the sea. They are among the few animals capable of digesting cellulose.

The first thoracic segment is fused with the head, the remaining seven usually being free; each bears a pair of legs (pereopods). The abdominal segments are smaller and the last segment is united with the telson. The abdomen bears five pairs of pleopods, which



A B

ISOPODA: (A) ASELLUS COMMUNIS, A COMMON FRESH-WATER ISOPOD; (B) CYLISTICUS CONVEXUS, A PILL BUG CAPABLE OF ROLLING INTO A BALL

function for swimming and/or respiration. The sixth pair of abdominal appendages, or uropods, may be slender and terminal (Asellota), may form a caudal fan with the telson (suborder Flabellifera) or may form a pair of platelike valves covering and protecting the pleopods (suborder Valvifera).

The eggs are carried in a pouch (marsupium) formed by overlapping platelike structures (oöstegites) attached to the bases of the pereopods. In some members of the families Sphaeromidae and Gnathiidae the marsupium is formed by invaginations of the ventral body wall and the oöstegites are reduced or absent. Newly hatched young lack the last pair of pereopods; otherwise they resemble the adults.

Parasitism has developed in several groups. Members of the family Cymothoidae live on the body surface or in the mouth or gill chamber of fishes; some even penetrate the body wall and bulge into the abdominal cavity, separated from it only by a thin membrane. Cymothoids are males when young and become females when fully grown. The suborder Epicaridea contains highly modified parasites of other Crustacea. Members of the most highly specialized family, Entoniscidae, live within the visceral cavity of crabs and are true endoparasites. *See* also CRUSTACEA.

(T. E. B.)

ISOPRENE, a colourless, volatile liquid that is made commercially by the thermal cracking of petroleum or coal gases and tars, and from the processing of isoamylene, propylene and acetone. It also can be made by the thermal decomposition of rubber and other terpenes. Liquid isoprene polymerizes readily to form rubberlike substances; *e.g.*, so-called synthetic natural rubber or butyl rubber. Such action seems to indicate that isoprene is the fundamental molecular unit of rubber. Isoprene has the formula C_5H_8; the specific gravity is 0.6808; and the boiling point is 34° C. *See* TERPENES.

ISOPTERA, an order of insects (*q.v.*), comprising the termites (*q.v.*) or so-called white ants of the tropics. *See* also SOCIAL INSECTS.

ISOPYCNIC, an adjective used in physics to mean constant density. In oceanography, isopycnic surfaces are considered in certain dynamic computations as the surfaces along which water particles actually move instead of along level surfaces, although the isopycnic surfaces are in most cases very nearly horizontal. The concept is similar to that of the movement of air on isentropic surfaces extensively used for computations and forecasting in meteorology. (H. R. B.)

ISORHYTHM (from the Greek *isos*, "equal," and *rhymos*, "rhythm"), the term used for a formal device of 14th- and 15th-century music consisting of a rhythmic pattern (*talea*) repeated throughout the work in different melodic forms. In the motets of Philippe de Vitry (1291–1361) the isorhythm is confined to the tenor part; in later works each voice often has its own *talea*.

ISOSTASY is a principle in earth science explaining why continents stand nearly three miles above the floor of the deep ocean, and why a major chain of mountains or an extensive plateau stands so high above the general continental surface. According to the principle, the solid rock underlying the deep ocean for a few tens of miles below sea level is heavier, volume for volume, than the average rock underlying a continent to the same depth, and still heavier than the average rock underlying a mountain chain or high plateau. The continents may be said to float on the earth's body, the needed upward pressure being supplied by the downward pressure of the heavy rocks under the ocean, aided by the weight of the water, muds and oozes of the sea floor. Also the weight of each broad mountain chain and plateau is approximately balanced by the weight of the somewhat heavier rock of the continent from which such high land rises. Thus the greater reliefs are almost perfectly compensated by corresponding variations of average density of the materials extending for several tens of miles below the surface.

Investigation shows that the balancing pressure is transmitted below in a weak layer of considerable thickness. To emphasize this weakness (largely caused by high temperature) the layer has been given the technical name asthenosphere. Since the continents and mountain chains are not flattening under their own weights, considerable strength must be ascribed to their rocks above the asthenosphere. Because such volcanic islands as Hawaii and St. Helena, representing enormous loads piled on the ocean floor, now show no sign of sinking, it seems clear that the solid rock under the deep-sea oozes is also strong. In both continental and oceanic regions many relatively narrow downwarps and upwarps of the rocky surface are not compensated and yet appear to be stable elements in the earth's topography. All around the earth, therefore, there is a strong surface layer of rock; this bears the technical name lithosphere.

The interface between asthenosphere and lithosphere is not level but is characterized by waviness, corresponding to the chemical composition and temperature (which control density) of the lithospheric rocks. To deduce the best reference spheroid for the figure of the earth, needed for accurate mapping, the geodesists have proved that the isostatic principle must be recognized; to allow for its influence they assume, for convenience in calculation, that the locus of compensation is a level passing through the lowest point at the bottom of the lithosphere. With that assumption these workers, using measured deflections of the plumb line and also measurements of the force of gravity at many stations on continents and islands and in submarines traversing the Atlantic, Pacific and Indian oceans, have greatly improved their conception of the earth's figure. (*See* GEODESY.)

By their own independent methods the seismologists have shown that the lithosphere under the oceans is decidedly denser than the average continental rock, and that the mountain chains are buoyed up by roots of rocky matter still lighter than the average rock of the continents.

In 1889 C. E. Dutton, a geologist, coined the name isostasy from the Greek *isostasios* ("in equipoise"; compare *isos*, "equal" and *statikos*, "stable"). He adopted the idea for two chief reasons: (1) the fact that the floor of each wide and thick mass of sedimentary rock laid on the lithosphere sinks by an amount not much smaller than the thickness of the mass; and (2) the fact that, when prolonged erosion removes a thick layer of rock from a broad mountain chain or plateau, the denuded area rises by a large fraction of the thickness of the vanished rock. From these facts he deduced the weakness of the asthenosphere and its ability to transmit the pressures caused by widespread loadings and unloadings of the lithosphere. The new name also meant for him that the major terrestrial reliefs are almost perfectly compensated by the horizontal variation of average density of the lithospheric rocks, allowance being made for the weight of the ocean water.

The isostatic principle is further illustrated by the basining of the lithosphere under the weight of the extensive icecaps that covered northwestern Europe and northern North America during the Pleistocene epoch, and by the recoil of the downwarped lithosphere since the loads were removed by melting.

The displacement of matter because of surface loading or unloading is called technically isostatic adjustment. The great viscosity of the earth's materials makes this a slow process. Recoil in the glaciated tract of Europe continues, though the icecap began to melt away 40,000 years ago and 7,000 years ago had only about 1% of its original weight. Time lag in adjustment for any transfer of surface load and the strength of the lithosphere are two manifest causes for some imperfection of isostatic balancing. Some investigators believe that a small degree of strength characterizing the asthenosphere itself is a third cause.

(R. A. D.)

ISOTHERM, a line on a map or thermodynamic chart connecting points having the same temperature. *See* THERMODYNAMICS; METEOROLOGY; WEATHER FORECASTING.

ISOTOPE. An isotope is one of two or more species of the same chemical element that have different atomic weights. Most of the elements, in the form in which they are found in the earth's crust and atmosphere, are mixtures of several isotopes. These mixtures are in almost unvarying proportions. For example, natural tin has ten isotopes, ranging in atomic weight from 112 to 124, but all specimens that have been examined have the average atomic weight 118.69. In other words, ordinary tin is nature's standardized blend of ten varieties of tin atoms, no two of which have

the same nuclear mass, although they are identical in all other respects.

The term isotopes was coined by F. Soddy in 1913 from the Greek *isos*, "equal," and *topos*, "place," to indicate substances occupying the same place in the periodic table of the elements; *i.e.*, having exactly the same chemical properties, but distinguishable from each other in some other way, such as mode of radioactive decay. With time the basic distinguishing feature of isotopes has been assigned to their respective atomic weights. Since chemical properties are determined by the positive charge on the nucleus (the atomic number) and by the consequent number of extranuclear electrons, this nuclear charge must be the same for isotopes. The differences in atomic masses of isotopes must therefore arise from differences in the masses of the nuclei involved.

Present-day usage tends to restrict the word isotopes to atoms having nuclei with masses differing by approximately whole numbers on the atomic weight scale. The general term for an atom characterized by the constitution of its nucleus is nuclide, although isotope has often been used loosely in the past for this purpose. An example of the correct usage lies in the following sentences: "The element chlorine has two isotopes with masses 35 and 37. These two isotopes are examples of nuclides with a mass difference of two."

This article will concentrate on the properties of isotopes related to the stricter interpretation of the name. For further information on atomic and nuclear structure and related topics, *see* MASS SPECTROSCOPY; NUCLEUS; RADIOACTIVITY.

Discovery of Isotopes.—Previous to the first decade of the 20th century it was generally assumed that the mass of a standard number of atoms of a chemical element (the atomic weight) was a fundamental characteristic of the element. It was furthermore usually assumed that all the atoms of an element were the same and, in particular, had the same mass. The fundamental importance attached to the mass in characterizing an element is illustrated by the periodic classifications of the elements, such as that of D. I. Mendeléyev, which were made by ordering the elements, with a few minor exceptions, according to their atomic weights.

The first evidence that two substances having the same chemical properties did not have to be physically identical came from the study of the radioactivity of the heavy elements. B. B. Boltwood in 1906 and, considerably more conclusively, H. N. McCoy and W. H. Ross in 1907 showed that ionium (a radioactive product of the disintegration of uranium) and radiothorium (a disintegration product of thorium) once mixed with thorium could not be separated from it by any chemical means. The two substances had radioactive properties quite different from those of thorium and could be shown to have atomic weights differing by several units from that of thorium. It was to cover situations such as this that Soddy devised the name isotopes.

Soon after the acceptance of these ideas as applied to the heavy chemical elements, there came indications that isotopy might exist in the main group of naturally occurring stable elements. J. J. Thomson, during a 1913 investigation of the behaviour of positively charged ions in electric and magnetic fields, found that whereas many substances, when ionized, did behave as if they were made up of identical molecules, the rare gas neon appeared to have a species in about 10% abundance that was 10% heavier than the main constituent. His student F. W. Aston first attempted to confirm this result by trying to change the atomic weight of neon by repeated partial diffusion of the gas through clay pipes. His results, although positive, were not definite enough to establish the idea of isotopy in light elements. Aston then went back to Thomson's methods and developed one of the first mass spectrographs (*see* MASS SPECTROSCOPY). With this he was able to show conclusively in 1919 that neon had two major constituents, one of mass close to 20 and the other with mass close to 22. The relative abundances were such as to explain the observed average atomic weight of 20.183.

The success with the element neon was followed by the discovery that chlorine had two isotopes (masses close to 35 and 37). Thereafter all the naturally occurring elements were examined and most of them were found to consist of more than one isotope.

Isotopes and Nuclear Structure.—With the discovery of isotopes, it became evident that all chemical elements that had atomic weights that were not close to integers consisted of mixtures of isotopes, each of which individually had a weight close to an integer. This finding has been confirmed and today it is well established that there are no isotopes with masses deviating from whole numbers by more than 0.1 atomic mass unit.

Modern ideas of nuclear structure picture the atomic nucleus as consisting of protons (*i.e.*, nuclei of normal hydrogen atoms) and neutrons. These two particles have nearly the same mass, close to unity on the atomic weight scale. This explains the integral masses observed for isotopes. The integer closest to the exact mass is known as the mass number (A) of the nucleus and is the sum of the number of protons (Z) and the number of neutrons (N) in the nucleus. The number of protons determines the positive charge and therefore the chemical properties of the atom.

Nuclei that have the same mass number are called isobars or isobaric nuclei; those that have the same number of protons, but varying numbers of neutrons, are isotopes; nuclei that have the same number of neutrons are known as isotones. The nuclear constitution of an atom is usually indicated by giving the chemical symbol (which determines the number of protons in the nucleus) with a superscript indicating the mass number and therefore, by difference, the neutron content of the nucleus. The superscript may be placed either before or after the chemical symbol. Thus Cl^{35} and Cl^{37} are the two stable isotopes of chlorine. The nuclei each have 17 protons. In the first isotope there are 18 neutrons, in the second 20 neutrons. The isotopes of hydrogen, H^1, $H^2 \equiv D^2$, $H^3 \equiv T^3$, have been given special names, protium, deuterium and tritium, respectively.

Finally we can define a class of nuclides that have the same number of neutrons and protons, and therefore the same mass number, but in which the nuclei are not in the same energetic state. Such nuclides are known as nuclear isomers.

Isotopes of an element differ among themselves (1) in any properties that depend on the mass; and (2) since the nuclear constitution is different, in all specifically nuclear properties. Thus they can be classified into stable isotopes and isotopes whose nuclei disintegrate spontaneously. The disintegration properties of radioactive isotopes, such as half life (time for half the isotope to disappear by decay) and modes of decay, are discussed under RADIOACTIVITY.

The stable isotopes are found as the constituents of the naturally occurring elements. They may also be produced by nuclear transformations. Although some radioactive isotopes exist in nature, most have to be prepared by artificially induced nuclear transformations.

Just as the nuclear stability varies from one isotope to another, so do other nuclear properties such as the nuclear radius, spin, magnetic moment and electrical quadrupole moment. Likewise the nuclear reaction probability often is very different in one isotope than in another. Thus, U^{235} undergoes nuclear fission when bombarded with slow neutrons; U^{238} does not. Similarly, only one of the eight isotopes of cadmium, Cd^{113}, has an extremely large probability of absorbing slow neutrons; the other isotopes are relatively inert. The stability toward spontaneous disintegration of the nucleus and, to a certain extent, nuclear reaction probabilities of isotopes are related to their energetic stability. According to the Einstein relation between mass and energy, the energy content of a system is determined by the mass—the lower the mass, the more stable the system. Although the exact masses of isotopes are close to whole numbers, the deviations are real and significant. In all known cases the mass is lower than that of the same number of separate neutrons and hydrogen atoms. Thus all known atoms are stable with respect to complete decomposition into neutrons and hydrogen atoms.

The detailed variations in mass of nuclides are conventionally measured in terms of the packing fraction, $f_{A,Z}$, of a nuclide of

atomic number Z and mass number A. The packing fraction is related to the exact mass, $M(A,Z)$, of the atom by the relation

$$M(A,Z)=A(1+f_{A,Z})$$

Packing fractions of nuclides (except for hydrogen and deuterium) lie between $+10\times10^{-4}$ and -10×10^{-4}. In the case of the stable isotopes of a given element, the packing fractions of the isotopes with masses of even numbers usually form a smooth curve as a function of A, with a minimum (and therefore increased stability) for the isotope of close-to-average mass number.

Variation in the Isotopic Composition of the Elements.—For most elements the relative amounts of the different isotopes in the natural mixture are very constant, irrespective of the source of the sample. In several cases the isotopic composition of elements in extraterrestrial sources such as meteorites has also been found to be the same as that of the same element on the earth's surface. However, elements that can be produced as a result of the few nuclear transformations (spontaneous or induced) occurring continually on the earth have been found to have varying isotopic content. Thus, the isotopic composition of lead depends on how much thorium or uranium has been nearby during geological time, and for how long (*see* RADIOACTIVITY, NATURAL). Likewise, since all the helium present today on the earth is the result of nuclear transformations, the relative amounts of He^3 and He^4 are not the same in the atmosphere as they are in helium from gas wells.

Smaller differences in the isotopic composition of the lighter elements arise from the effect of mass on the rates and equilibriums of naturally occurring chemical and physical processes (*see* below). Thus the deuterium content of hydrogen from the water of the Dead sea is higher than that of hydrogen from most other sources. Even an element as heavy as sulfur has been shown to have an S^{34}-to-S^{32} ratio varying by up to 7%.

Isotopic Composition of Elements.—In spite of such small variations in the constitution of the light elements and the variation in the composition of some others from special sources, the isotopic composition of the great majority of the chemical elements is very constant. The table indicates the isotopic composition of the elements as they occur naturally, giving for each element the mass numbers of the isotopes and the percentage of the atoms of the normal element that consist of that particular isotope. Unless indicated, all the isotopes listed are stable.

It is seen by examination of the table that there are stable representatives of all mass numbers between 1 and 209 inclusive, except for mass numbers 5 and 8. There are no stable isotopes of any element with these mass numbers. Elements of even atomic number have many more stable isotopes than those of odd atomic number. These latter never have more than two, almost always of odd mass number, whereas the even-atomic-numbered elements, except beryllium, have at least two isotopes and tin ($Z=50$) has ten.

The 85 naturally occurring chemical elements are made up principally of 287 isotopes, 271 of which are stable. The other 16 isotopes are radioactive with half lives comparable to the age of the earth ($\sim4.5\times10^9$ years) or longer. All the stable isotopes that are known occur in the chemical elements as we know them and in amounts that represent significant percentages of their respective elements.

An important theoretical interest in the isotopic composition of the elements arises from this being one of the few quantitative evidences available of the process by which all nuclei were originally formed. The relative cosmical abundances of nuclides differing in proton content (Z) have obviously been badly distorted by chemical and physical processes occurring during geological time. Compared with this, the isotopic composition of the elements is very constant. Any theory of the formation of complex nuclei must consider regularities such as the preponderance of neutron-rich isotopes in the heavy elements, the frequent preponderance of light isotopes among the light elements and the generally low abundances of odd-mass-numbered isotopes of even-numbered elements.

Relationship of Chemical Atomic Weights to the Existence of Isotopes.—The chemical atomic weight of an element is defined as the weight of a standard number of atoms of the element on a scale where the weight of the same number of oxygen atoms is 15.9994. (If this standard number of atoms is taken as Avogadro's number—$[6.02486\pm0.00016]\times10^{23}$ atoms—the actual weight in grams is the gram atomic weight.) These weights are of great practical value in chemical analysis. As mentioned above, because of the existence of the phenomenon of isotopy, they have lost their fundamental interpretation as accurate measures of the masses of individual atoms. Thus there is no chlorine atom that has a mass on the atomic weight scale of 35.453 (the listed chemical atomic weight of chlorine); instead normal chlorine consists of atoms that have a mass of either 34.96905 or 36.96733.

The existence of isotopes and the known or expected small fractionation of isotopes in chemical and physical processes set limits to the accuracy to which atomic weights have meaning, unless the exact isotopic composition is specified. It was pointed out by H. C. Urey and L. J. Greiff in 1935 that this limit had probably already been reached in the case of several light elements whose atomic weights were being quoted to a thousandth of an atomic weight unit. Even the standard element oxygen could be expected to show a variation in atomic weight in the fourth decimal place as a result of variations in isotopic composition.

Naturally Occurring Radioactive Isotopes.—Radioactivity occurring in nature arises from several sources. Thus there are the long-lived radioactive species (half lives greater than a few hundred million years) that have survived since the formation of the elements. The naturally occurring isotopes of thorium and uranium are of this type. Likewise potassium, rubidium and several other elements are slightly radioactive because of the presence of long-lived radioactive isotopes (*see* Table). Next there are the shorter-lived radioactive isotopes that are present because their disappearance by decay is balanced by continual replenishment from some source. Thus some of the isotopes of thallium, lead, bismuth, thorium and uranium and all the isotopes of the other elements between bismuth and uranium are radioactive and present in small amounts because they are being continually produced in the radioactive decay of very long-lived parents (isotopes of uranium and thorium). The most famous example of this type is an isotope of radium (Ra^{226}) that is present in uranium ores to the extent of 3.4×10^{-7} g. per gram of uranium.

Cosmic radiation incident on the earth's atmosphere is another such producer of slight amounts of radioactive isotopes. This, for example, is the source of the minute amounts of a radioactive isotope of carbon, C^{14}, that is present in all living tissue to the extent of about 12 disintegrations per minute per gram of carbon. The half life of this carbon isotope is about 5,570 years. W. F. Libby developed the radiocarbon method of age determination of archaeological and geological specimens, useful in the range from 1,000 to 30,000 years, from the presence of this cosmic-ray-produced C^{14}. (*See* also RADIOCARBON DATING.)

These and other less important sources make most matter very slightly radioactive. In addition to these natural sources, the use of nuclear energy is producing, as by-products, radioactive isotopes that may become significant supplements to the natural radioactivity of the surface of the earth. Thus the explosion of megaton nuclear devices scattered sufficient radioactive debris all over the world so that all humans absorbed detectable amounts of the radioactive nuclides Cs^{137} and Sr^{90}.

Radioactive Isotopes.—Radioactive as well as stable isotopes of all the elements have been prepared. By mid-20th century there was information on more than 1,100 radioactive nuclides, and the list was still expanding. Most of the radioactive nuclides are prepared by artificially induced nuclear transformations (*see* RADIOACTIVITY). The elements technetium ($Z=43$) and promethium ($Z=61$) and all the elements with atomic number greater than that of bismuth ($Z=83$) have only radioactive isotopes.

In the case of xenon, besides the 9 stable isotopes there are 20 known radioactive species with half lives ranging from about 1 second to about 35 days. Six of these are nuclear isomers. At the other extreme, hydrogen has only three known isotopes, two stable and one radioactive; one of the isotopes, tritium, occurs

*Isotopic composition varies slightly with source.
†Isotopic composition varies considerably with source.
‡Isotope radioactive.
Source: This table has been taken almost entirely from D. Strominger, J. M. Hollander and G. T. Seaborg, "Table of Isotopes," *Rev. Mod. Phys.*, 30:585, no. 2, part ii of 2 parts (April 1958).

naturally, however, in only minute amounts (*see* HYDROGEN).

Effect of Isotopic Substitution on Physical Properties of Substances.—The rather belated discovery of isotopes as well as the difficulty of separation is of course a reflection of the smallness of the effect of mass on most physical and chemical properties. For example, the electronic energy states of atoms or molecules depend on the nuclear mass through the reduced mass, μ, of the electron-nucleus system; μ is defined by

$$\mu = \frac{m_e m_n}{m_e + m_n} \approx m_e\left(1 - \frac{1}{1837A}\right)$$

where m_e and m_n are the electronic and nuclear masses and A is the mass number of the nucleus. It is seen that such effects are of the order of 5×10^{-4} for hydrogen and correspondingly smaller for heavier atoms. In the case of hydrogen, however, the shift in electronic energy levels in going from protium to deuterium is easily detected spectroscopically, and was in fact the mode of discovery of deuterium by Urey, F. G. Brickwedde and G. M. Murphy in 1931.

The other consequence of the presence of isotopes on the optical spectra of atoms arises from the interaction of the magnetic field of the nucleus, if it has one, on the electrons of the atomic system. The result is a splitting of a spectral line into several components (called the hyperfine structure). The number of components and the separations depend upon the spin and magnetic moment of the nucleus and on the nature of the electronic state. Since this phenomenon depends on nuclear properties it varies from isotope to isotope. It is most important for heavy elements, but even there it is difficult to measure. Analysis of hyperfine structure is an important method of determining nuclear spins and magnetic moments.

Molecular spectra are much more affected than are atomic spectra by the presence of isotopes, for these spectra reflect in part the vibrational and rotational energies of molecules. The quanta of vibrational and rotational energies are directly dependent upon the masses of the atoms involved and therefore upon the presence of isotopes. It was by examination of molecular spectra that several isotopes (for example, C^{13}, N^{15}, O^{17}, O^{18} and Si^{30}) were discovered.

The presence of isotopes affects physical properties other than spectroscopic. There is, of course, the direct effect of mass on the density of a substance. Because densities can often be measured extremely precisely, a density determination has been used in special cases to establish isotopic composition.

Another direct effect of mass on physical properties is the effect on the rate of diffusion of gaseous atoms and molecules. It has long been known that the rate of effusion of a gas through a hole of size smaller than the distance between the gas molecules varies inversely as the square root of the mass. It was by taking advantage of this property that F. W. Aston first achieved a partial separation of the neon isotopes, and basically similar processes are used today.

In general, other physical properties of substances are significantly affected by the presence of isotopes only at low temperatures and in the case of molecules of low molecular weight. Accurate measurements, however, are continually detecting small differences in physical properties of substances related by isotopic substitution. For example, deuterium melts at 18.65° K. and boils at 23.6° K.; the corresponding temperatures for hydrogen are 13.95° K. and 20.38° K. Heavy water (D_2O) has a melting point 3.8° higher and a boiling point 1.4° higher than ordinary water.

Regarding the incompletely understood phenomenon of superconductivity at low temperatures, it is of interest that the temperature at which certain metals transform to the superconducting state is affected by the isotopic composition of the metal.

Effect of Isotopic Substitution on Chemical Properties.—It has usually been assumed that isotopes and substances differing only in the presence of different isotopes have the same chemistry. However, accurate studies, particularly with deuterium, have indicated that the chemistry of isotopes is identical only in the limit of large masses and high temperatures. Whenever quantum mechanical effects are important, and in general they are most important for light masses and low temperatures, the masses of the atoms involved can be expected to affect the situation and, thus, the result to be sensitive to the isotope involved. This can be illustrated by the following example: The forces between atoms are derived from the electric and electronic structures of the atoms. As indicated in the discussion on electronic states of atoms, these are essentially indistinguishable for different isotopes of the same element. The actual motion of the atoms produced by these forces, however, is affected by the atomic mass. In a given potential, the frequency of vibration and, therefore, the quantum of vibrational energy will vary inversely as the square root of the mass of the system. This affects not only the vibrational spectrum but also means that the zero point energy, the lowest energy state of the system, will be lower for heavier isotopes.

In this way it is quite easy to calculate quantitatively that the energy needed to dissociate the gaseous D_2 molecules into atoms at absolute zero will be 1.81 kg.cal./mole ($\sim 2\%$) higher than that needed to dissociate the H_2 molecule. With elements heavier than hydrogen this effect becomes successively smaller. It remains always true, however, that, because of the lower zero point energy, more energy is required to break a chemical bond involving a heavier isotope than to break a bond involving a lighter one.

Using quantum mechanics to estimate the effects of mass, equilibrium constants can be calculated by statistical methods for so-called exchange reactions. These are chemical reactions in which the reactants and products differ only in the exchange of isotopes. For example, the reaction

$$CO_2^{18} + 2H_2O^{16} \rightleftarrows CO_2^{16} + 2H_2O^{18}$$

has an equilibrium constant given by

$$K = \frac{P_{(CO_2^{18})} \times P_{(H_2O^{16})}}{P_{(CO_2^{16})} \times P_{(H_2O^{18})}}$$

where $P_{(CO_2^{18})}$ designates the pressure exerted by CO_2^{18} at equilibrium, $P_{(H_2O^{16})}$ that of H_2O^{16}, etc.

The value of the equilibrium constant was calculated by Urey and Greiff in 1935 to be 1.128 at 0° C. and 1.110 at 25° C. It is seen that carbon dioxide in equilibrium with water will contain oxygen with slightly higher O^{18} content than does the water. It is also seen that at higher temperatures the oxygen in the carbon dioxide and in the water tend toward more equal isotopic compositions.

Predictions such as the above have been verified experimentally. Likewise it has been demonstrated that the rates of chemical reaction are affected measurably by isotopic substitutions. In general, the effects are greatest for the lightest elements and decrease with increasing temperature. Thus chemical reaction rates involving deuterium compounds may be up to several times slower than those involving the corresponding hydrogen compounds. This effect has been extensively used to investigate the mechanism of reactions that may involve transfer of hydrogen atoms. In view of the measurable effects of isotopes on both chemical equilibriums and the rates of chemical reactions, it is not surprising that the isotopic composition of the lighter elements in nature shows a definite variation from source to source.

Separation of Isotopes.—This term is generally taken to mean the production of an element with an isotopic composition significantly different from that of the natural element. In the extreme, such a process produces a relatively pure isotope. For most purposes, however, such as chemical or biological tagging experiments, complete separation is not necessary.

It has been mentioned that Aston first attempted to confirm Thomson's discovery of isotopes in neon by trying to separate them. He allowed part of a sample of normal neon to diffuse at low pressure through clay pipes and repeated the process many times on the fractions obtained. He reported in 1913 that in this way he had been able to change the atomic weight of neon by almost 0.5%. Subsequent attempts by many persons using many different methods on different elements did not produce significantly greater separations. Finally, G. Hertz, in 1932, used the same basic methods as had Aston originally but arranged the diffusing

units in a cascade (*see* below). He produced neon with the heavier isotope, Ne^{22}, more than twice as abundant as the lighter one, Ne^{20}. In normal neon, Ne^{22} has an abundance of only 10%. Since these pioneer achievements, isotope separations by various methods have become increasingly common. Today small samples of almost any element with distorted isotopic abundances are available for research purposes. A few isotopes, *e.g.*, D and U^{235}, are separated on a large scale as a part of nuclear energy programs.

In almost all the methods used for separating isotopes a basic step is repeated many times to achieve the desired extent of separation. A process is judged by two factors that have different relative importance in different situations. One is the separation factor per stage (f). This is defined as the ratio of the relative concentration of a given isotope after the basic step in the concentrated fraction to that in the stripped fraction. The latter is ordinarily indistinguishable from the original concentration entering the unit. Thus if the normal isotopic composition of an element is n_1 and n_2, and if, after one stage of the process, it becomes n_1' and n_2', then

$$f = \frac{(n_1'/n_2')}{(n_1/n_2)}$$

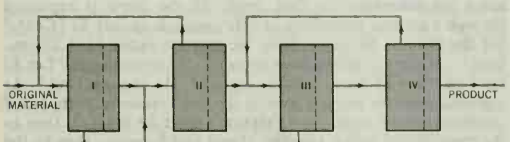
The second important factor is the amount of material processed per stage. In general, processes operating with good separation factors produce only small amounts of material and vice versa.

In order to achieve desired over-all separations with processes of low separation factors, many repetitions of the basic stage are necessary. For example, to get 90% U^{235} starting with normal uranium and a process with a separation factor of 1.0043 (a high one for a diffusion process), 1,660 stages are necessary.

Such large numbers of stages can be used only if they are arranged in a manner that does not waste material. Such an arrangement is the cascade used by Hertz in 1932 and thereafter in most of the large-scale separation methods. A cascade arrangement of four stages is illustrated in the drawing. The boxes I, II, III and IV represent units. Into one of them (*e.g.*, III) goes a certain amount of feed material from the left. As a result of the operation of the unit, a small fraction of this feed material comes out of the unit toward the right, concentrated in the isotope in question. It forms the feed material for unit IV. The great majority of the feed material for unit III is slightly depleted in the isotope and is returned to become part of the feed material for the unit II. As a result of the operation of the cascade, the material coming out at the right from unit IV is concentrated in one isotope; the material being rejected by unit I is depleted in the isotope. The theory of such cascades is similar to that of multiplate distillation columns and countercurrent solvent extractions.

Historically, of course, a unit in which a gas was diffused through small pores of a solid was the first type used in such a cascade (Hertz). Diffusion units are also used in the large-scale production of U^{235} in the United States. The gas employed is uranium hexafluoride. Diffusion processes, in spite of low separation factors, can be designed to handle large amounts of material and are susceptible to engineering for continuous automatic operation.

At the other extreme of separation factors is the electromagnetic separation process, which can produce small amounts of very enriched isotopes in one step. These units are simple mass spectrographs designed to collect the mass-analyzed beams instead of merely recording their presence. Large numbers of such units (called calutrons) were used in the United States in World War II together with the diffusion process to produce the U^{235} for nuclear bombs. In general, large-scale operations appear to be more



CASCADE ARRANGEMENT OF FOUR STAGES FOR SEPARATING ISOTOPES

economical with the diffusion process. On the other hand, the electromagnetic process is more versatile. It was used both in the United States and Europe to produce milligram quantities of almost any element with a distorted isotopic composition.

For the isotopes of hydrogen (deuterium and tritium) electrolysis of water solutions proved an effective way of separating isotopes. The liquid remaining after most of the water of, for example, an NaOH solution has been electrolyzed is concentrated in the heavier isotope. This water can be distilled away from the NaOH and made into a fresh NaOH solution and the process repeated. The separation factors in such a process depend upon the electrodes used and can be as high as seven. This, of course, is much higher than is ever encountered with other elements. The electrolytic process was used in Norway from the middle 1930s for the production of ton quantities of heavy water (D_2O). Libby used electrolytic concentration in his measurements of the tritium content of rains.

The chemical exchange method is another that often uses multistage cascades to increase the effect of a small separation factor per stage. Thus Urey made use of the exchange reaction

$$HC^{13}N(\text{gas}) + NaC^{12}N(\text{solution}) \rightleftarrows HC^{12}N(\text{gas}) + NaC^{13}N(\text{solution})$$

which has an equilibrium constant a little less than unity in a process that produces carbon with more than 20% C^{13} (instead of the normal 1.1%). Similar schemes were devised by Urey and co-workers to produce nitrogen and sulfur samples enriched in N^{15} and S^{34}. During World War II catalysts were found that would achieve equilibrium in the exchange reaction

$$H_2(\text{gas}) + D_2O(\text{gas}) \rightleftarrows D_2(\text{gas}) + H_2O(\text{gas})$$

The reaction has an equilibrium constant of about three. This exchange reaction process as well as the straight separation of D_2O from H_2O by distillation are much more economical in most places than the electrolytic process. They have been used to produce the ton quantities of D_2O needed for nuclear reactors.

In addition to the methods described, which have been used in relatively large-scale separations, isotope separations have been achieved using centrifugation and thermal diffusion (diffusion of gases in the presence of a thermal gradient).

Uses of Isotopes.—The uses of isotopes can be divided roughly into two categories. In one, application is made of some particular nuclear property of the isotope—either its radiations upon decomposition or some nuclear reaction probability. Since such uses do not depend upon the principle of isotopy, they will not be discussed in detail here.

The other class of application of isotopes depends on the fact that, to a very good approximation in most cases, all isotopes of an element have the same chemical properties. This makes it possible to label or tag an element by distorting its isotopic composition. The distortion is accomplished by the addition either of a radioactive isotope or of one of the stable isotopes of the element. The behaviour of this element can then be followed either by measurement of the radioactivity or by analysis with a mass spectrometer. The isotope added is often referred to as a tracer or indicator. The use of labeled atoms in this manner was introduced by G. von Hevesy and F. A. Paneth in 1913. They used a radioactive isotope of lead (radium D or Pb^{210}) to study the solubility of lead salts. Since then, with the availability of radioactive or stable isotopes as tracers for almost all the elements, the use of labeled elements for many chemical, biological and industrial purposes has become widespread.

A type of investigation made possible by the availability of isotopes is that of exchange reactions. In these there is no change in either the type or number of chemical species involved. Studies on the equilibriums and rates of such reactions are important not only for the separation of isotopes but also as a means of understanding chemical reactions in general and as a prelude to other applications of isotopes.

Isotopes have found extensive application in chemical analysis. An example is the isotope dilution method, used in many variations with both stable and radioactive isotopes. All the variations have in common the feature that the chemical separation procedures

used do not have to be quantitative in order to provide quantitative answers. Thus to analyze for an element A in a mixture, a known amount of a tracer for A is added at the start. A chemical separation of A is carried out, yielding A in a chemically pure form. The fraction of the added tracer recovered measures the efficiency of the process. This, together with the absolute amount of A recovered, as measured either by weighing or by other conventional means, determines the total amount of A present in the original mixture.

A second analytical application, often called activation analysis, involves nuclear reactions and actually analyzes for particular isotopes. If these are present in a normal element the result is an analysis for the element. Thus the production of a radioactive isotope of an element upon exposure of a sample to slow neutrons measures the amount of isotope of one lower mass number present in the sample. The method can be calibrated by exposing a known amount of the element to the same neutrons and measuring the production of the radioactivity involved.

A third analytical application of isotopes and particularly of radioactive ones arises from the sensitivity of detection instruments used in isotopic analysis. An activity of 100 disintegrations per minute (easily measured) of an isotope with a one-day half life corresponds to about 200,000 atoms. Several of the transuranium elements have been discovered through their radioactive properties and the complete experiments involved less than 100 atoms. More generally, the behaviour of elements at very low concentrations can be studied using radioactive isotopes. Also, starting with larger amounts of radioactivity, the occurrence of very improbable reactions can be detected.

Specific applications of the above and other techniques of tracer application are too numerous to cover in detail here. It is true, however, that isotopes, both stable and radioactive, play an indispensable role in research on photosynthesis. Another area that might be singled out is the study of the animal metabolism of different types of food. It was established through the use of tracers that there is a continual exchange between almost all injected substances and those present in the animal body. Even portions of bones and teeth are accessible to exchange with injected calcium and fluorine.

In medicine the principal applications of isotopes involve the radioactive ones. The use of radium in the treatment of cancer has a long history. Later other radionuclides became available in sufficient quantity and were also used for the same purpose. Probably the outstanding example of the application in medicine of a radioactive isotope is the use of 8.0-day I^{131} in the diagnosis and treatment of thyroid ailments.

The industrial applications of isotopes began in the 1950s. An accomplished development was the use of gamma-emitting radioactive isotopes such as radium or Co^{60} instead of an X-ray machine for the radiography of metal castings. Such sources have the advantage of compactness and ruggedness, which often make them preferable to electric machines. The convenience of radioactive isotopes in furnishing high-energy radiations in a small space has found application in several other situations. Thus the ionization of air produced by these radiations is used to prevent the accumulation of undesirable static electric charges. Similarly the scattering of these radiations by thin films, being a sensitive function of the thickness of the film, is used widely in thickness gauges.

Isotopes of Importance in Nuclear Energy Programs.—The development of nuclear energy for both weapons and power has often depended upon the characteristics of individual isotopes rather than that of the natural mixture occurring in elements. Thus U^{235} is the only isotope in natural uranium (in fact the only naturally occurring nuclide) that can support a chain reaction. In concentrated form (*i.e.*, separated from its diluent U^{238}) it can support a fast neutron chain reaction and therefore can be used for nuclear explosives. In its ordinary dilution it can be used to support a slow neutron (thermal) chain reaction. The extra neutrons in a chain-reacting pile can then be used either to make plutonium (Pu^{239}) from U^{238} or U^{233} from Th^{232}. Both Pu^{239} and U^{233} have fissionability characteristics comparable with those of U^{235} and so are usable either in weapons or as the basis for controlled release of nuclear energy.

In addition to these heavy nuclides, there are several isotopes of the light elements that are of importance in nuclear energy developments. They are useful either as moderators (to slow down neutrons) in uranium chain-reacting piles or as direct sources of nuclear energy. In the former category helium and carbon (in the form of graphite), and hydrogen, deuterium and oxygen (in the forms of light and heavy water) were the first to be used. In the second category, the large-scale conversion of D^2 into He^4 was first accomplished by the U.S. in Nov. 1952 in a hydrogen bomb explosion on a Pacific atoll. The next step was to achieve the controlled release of such thermonuclear energy.

Nuclear Isomers.—Nuclear isomers are nuclei which have the same charge (Z) and mass number (A) but represent different energy states. Atoms differing because of the presence of nuclear isomers as their nuclei are isobaric isotopes. One of two nuclear isomers must be unstable with respect to de-excitation. Although the existence of any excited state is in a sense an example of nuclear isomerism, the term is ordinarily applied only to cases where the excited state has a measurable half life for decomposition (greater than about 10^{-10} seconds). Such nuclei are called metastable and are usually designated by an asterisk (*) or an *m* after the mass number. Thus Br^{80*} and Br^{80} represent a pair of nuclear isomers. Br^{80*} decays to Br^{80} with a 4.5-hour half life.

The first case of nuclear isomerism was discovered by O. Hahn in 1921. He found two nuclear species having distinctive radioactive properties that had to be assigned the nuclear constitution expressed by Pa^{234}. By mid-20th century there were more than 160 pairs of nuclear isomers known, as well as a few cases of triple isomerism. Since nuclear isomers have the same charge and differ in mass by less than a few thousandths of a mass unit (isotopes differ from each other by at least one mass unit), it is unlikely that atoms differing only in the presence of nuclear isomers as their nuclei will have detectable differences in chemical or physical properties.

ISPARTA, a town and capital of the *il* (province) of the same name in the southwestern corner of inner Anatolia, Turkey, lies on the edge of a fertile plain at the foot of the Aglasundag, 110 mi. W. of Konya. Pop. (1960) 36,201. It is an important centre for rose oil, of which the province is the leading producer in Turkey. The local animal husbandry has assisted the growth of rugmaking, the important home industry. The rugs, which have a wide reputation, are made chiefly by women and girls. The town has many woolen-yarn workshops including a large state-owned mill. It is connected by rail and road with Izmir, Afyonkarahisar and Egridir. On the site of the Byzantine town of Baris, Isparta was the capital of the amirate of Hamid in the 14th century. It suffered severely from earthquake in 1889.

ISPARTA IL is 3,193 sq.mi. in extent and had a population (1960) of 242,352. The chief food crops are wheat, barley and vegetables, and much fruit, especially cherries, is grown on the plain. There is inland drainage to the Egridir and Burdur lakes.

(N. TU.; S. ER.; E. TU.)

ISRAEL, in the Bible, is the name given to the patriarch Jacob (*q.v.*) as a surname (Gen. xxxii, 28) and to the people reckoned as his descendants. The etymology and meaning of the name are uncertain; in Gen. xxxii, 28 the name is explained through a popular etymology as "He contends against El [God]," but the form of the name, *yisra 'el*, suggests rather "Let El contend." Modern scholars have proposed the etymologies "Let El rule" and "Let El shine." Philo suggested "He who sees God." As a gentilic noun the name is given in the Old Testament to the tribal confederation of Israel (*see* TWELVE TRIBES OF ISRAEL), then to the monarchical nation ruled by David and Solomon, then to the northern portion of the divided kingdom which seceded *c.* 920 B.C. from the dynasty of David. The prevailing biblical use of the name, however, signifies a theological rather than a political con-

ception. In all periods of the Bible Israel was conceived as a theologically based society, never as a purely secular tribal or political society. This can be seen in the transfer of the title Israel to the kingdom of Judah after the fall of the kingdom of Israel *c.* 721 B.C.; for Judah was the heir and successor of the theological character of Israel, although its name as a political society remained Judah.

The theological character of Israel rests upon the relations between Israel and the God of Israel, Yahweh (*q.v.*). These relations were understood in a manner to which no true parallel appears in the thought of the ancient near east. The numerous biblical allusions which identify Yahweh as the God of Israel and Israel as the people of Yahweh are, of course, superficially no different from similar phrases to be found elsewhere in ancient near-eastern literature. The bond of union between Israel and Yahweh, however, is represented as election and covenant. The election is the antecedent and gratuitous choice by Yahweh of Israel to be his people (Isa. xli, 8–9). Yahweh is the God who was worshiped by the patriarchs, the ancestors of Israel, but in the traditions of the patriarchs he is a family god, not the god of a people. The act by which Yahweh makes Israel his people is also conceived as a creative act by which he brings Israel into existence (Isa. xliii, 15). Israel is the adopted first-born son of Yahweh (Ex. iv, 22).

The acceptance of the choice by Israel furnishes the terms of the mutual agreement or covenant by which Yahweh and Israel are united (Ex. xix, 1–8; *see* also COVENANT: *In Religion*). This agreement is more accurately described as unilateral rather than as mutual; it is conceived in terms of ancient near-eastern treaties in which an overlord imposes a covenant upon a vassal. While Israel freely accepts Yahweh as its god, it has no choice in the sense that it makes no difference whether it accepts Yahweh or not. Yahweh vindicates his claims upon Israel by delivering Israel from the bondage of Egypt. This deliverance entitles him to be called king and saviour of Israel (Isa. xliv, 6). A person is not entirely free to accept or to reject his creator, his saviour, his father. This becomes clear progressively as the people come to accept the faith that Yahweh is the one true God, the creator of the universe. The theme of power also is present, and Israel is the servant or slave of Yahweh (Isa. xli, 8–9). The title of slave in this context is not pejorative; it is given both in the Bible and in other ancient near-eastern literature to those officers who were most intimately associated with the king in government and in his household. To be a royal slave was a dignity, not a degradation. By the covenant Israel accepts Yahweh as its exclusive and sole god and pledges itself to worship no other god (Ex. xx, 2–3; Deut. v, 6–7). It acquires a sacred character and becomes holy to Yahweh, as a priest is holy among men (Ex. xix, 6; Jer. ii, 3).

In the literature of the Old Testament which is later than the fall of the kingdom of Israel (*c.* 721 B.C.) the title of Israel is used almost exclusively in a theological sense. The theological Israel becomes an ideal; and as an ideal it is the whole Israel of the 12 tribes. The messianic restoration of Israel includes all the 12 tribes of historic Israel (Jer. xxxi). In exilic and postexilic literature (after 587 B.C.) the name of the community as a real society is Judah, and its members are Judahites (Jews). This is the usual designation employed by Jews themselves when dealing with foreigners and by foreigners of Jews. The term Israel appears only within the community and then only in its ideal theological sense. In the literature of Hellenistic Judaism outside Palestine the term is rare in any sense.

The use of the title Israel in the New Testament reflects the usage of Judaism with modifications arising from the relations of the new faith to the faith of its origin. In the Synoptic Gospels and Acts i–xii the title is used of the people as a religious society. In other New Testament writings the schism between the primitive church and Judaism is reflected in the use of the terms Israel and Jews. "Jews" becomes the ordinary designation of the people even as a religious community. In Rom. ix–x the question becomes explicit whether the Jews after rejecting the Messiah Jesus are entitled to be called the people of God and therefore whether they are entitled to the name Israel. Paul distinguishes the Israelite by blood (Rom. ix, 6) or by the flesh alone (I Cor. x, 18). It is somewhat surprising that the New Testament writers do not explicitly claim for the Christian community the title of the new true Israel. The idea is approached in Gal. vi, 16, "the Israel of God"; but the force of the phrase is not altogether clear. The ideal Israel of the messianic restoration is retained in the New Testament. It is explicit in Rev. vii, 4–8 and xxi, 12 and is suggested in Matt. xix, 28 and Luke xxii, 30, where the apostles "judge" (*i.e.*, rule) the 12 tribes of Israel. The eschatological church and the eschatological Israel become one.

The political title is revived in its application to the Jewish state established in the British mandate of Palestine in 1948. The claims of the new state both to the title and to the territory are (at least for the Orthodox) implicitly theological as much as they are political. They rest not upon continuous occupation but upon a historic grant in virtue of which the sons of Israel settled in Canaan. The grant as described in Israelite traditions was not a grant from a political sovereign but from Yahweh, the God of Israel, who gave Canaan to his people for a possession.

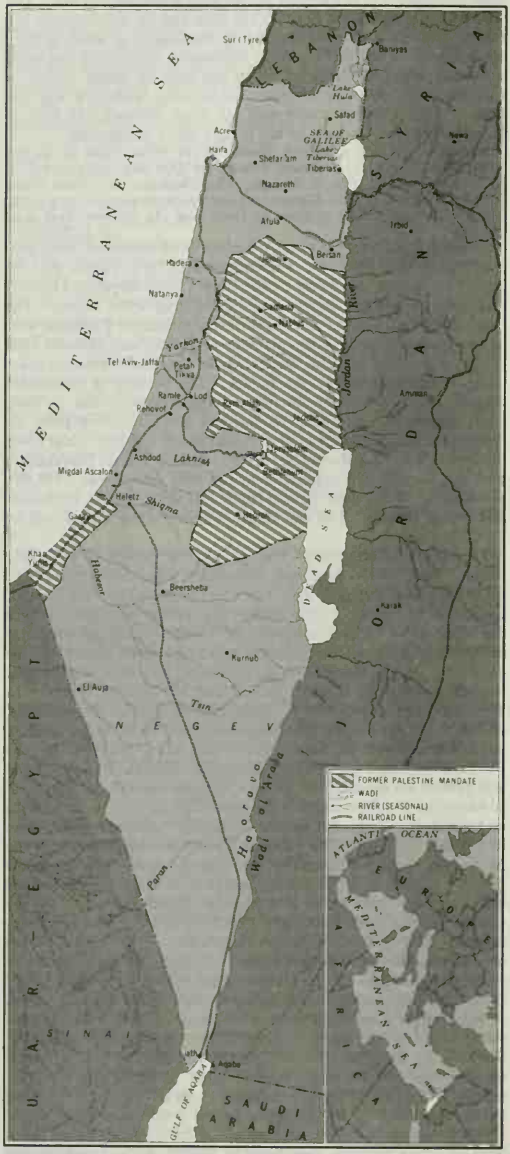
ISRAEL (MEDINAT ISRAEL), a republic of southwest Asia, proclaimed on May 14, 1948, is bounded north by Lebanon, east by Syria and Jordan, southwest by the United Arab Republic (Egypt) and west by the Mediterranean. Total area 7,993 sq.mi. The territory includes all the area of formerly mandated Palestine west of the Jordan except for the plateaus of Judaea and Samaria (annexed by Jordan) and the Gaza strip on the Mediterranean coast which is administered by the U.A.R. The country is subdivided administratively into six districts: Jerusalem, with the corridor from the coastal plain into the Judaean hills; Tel Aviv-Jaffa, including the southern part of the coastal plain; Central (chief town Ramle); Haifa; Northern (Nazareth); and Southern (Beersheba), with the Negev. The population at the 1961 census was 2,179,491 of whom 1,932,357 were Jews, 170,830 Muslims, 50,543 Christians and 24,282 Druzes. The seat of government is the Israeli part of Jerusalem (*q.v.*).

Physical Geography.—The geology of Israel is relatively simple. Most of the country is underlain by sedimentary rocks of Secondary and Tertiary age. In the coastal plain, the vale of Esdraelon and upper Jordan valley, Quaternary alluvium overlies the older rocks. The Secondary and Tertiary rocks are predominantly chalky or dolomitic limestones (laid down under marine conditions on the margins of the Arabian platform), which form the hill country of Galilee, Judaea and the central Negev. In Tertiary times folding arched up the hills along a north-south axis, and in the Negev along northeast-southwest axes, while faulting is responsible for the remarkable Rift valley occupied by the Jordan river, Dead sea and Gulf of Aqaba. The vales of Esdraelon and Jezreel are downfaulted along a northwest-southeast axis.

Along the Mediterranean is the coastal plain; it is narrow north of Acre and at Haifa, but widens southward in Sharon and Darom to a width of 20 mi. The vales of Esdraelon and Jezreel join the Acre plain to the Jordan valley, and like the coast plain are below 300 ft. Upper Galilee is the highest part of Israel, with rounded hills rising to 3,963 ft. at Har Meiron (Jabal Jarmaq). Lower Galilee lies between 1,000 and 2,000 ft., and its hills are more broken. The Galilean hills terminate eastward in a steep scarp overlooking the upper Jordan valley. A small portion of the limestone Judaean hills, the Jerusalem corridor, lies within Israel; between the Judaean hills and the coast plain is the foothill region of the Shefela (lowland) between 500 and 1,500 ft. The Jordan valley lies at 500 ft. above sea level at Dan on the northern border, but at Lake Tiberias (Sea of Galilee) the level is 696 ft. below sea level and the Dead sea surface 1,302 ft. below the Mediterranean. The Rift valley is continued south to the Gulf of Aqaba, but its floor rises to 500 ft. above sea level midway. The Negev (*q.v.*), or south, is clearly marked off by its aridity. Its northern limit is a line through Beersheba to Sodom. The northwestern Negev is a plain of sand dunes and stony desert. This rises gradu-

ally to the central Negev heights, at more than 3,000 ft.

The Jordan river rises north of the Israel-Lebanon and Israel-Syria borders. It flows through lakes Hula (Yam Hulata) and Galilee (Kinneret), enters Jordan south of Beisan (Beit-Shaan) and empties into the Dead sea. The inflow into the Dead sea is balanced by evaporation, thus accounting for the high salt concentration, eight times that of the average for the oceans. Other rivers in Israel are small and mostly seasonal (wadies), except for the Qishon, which enters the sea near Haifa, and the Yarkon (Auja), which enters at Tel Aviv. The Yarkon supplies water to Tel Aviv and Jerusalem and water is carried by pipeline to irrigate the northern Negev.



ISRAEL, SHOWING THE TERRITORY WHICH WAS FORMERLY A PART OF THE PALESTINE MANDATE

Climate.—Israel north of Beersheba has a Mediterranean climate, but the Negev is arid. The Negev lies south of the 8 in. annual isohyet; there cultivation is impossible without irrigation. In the plains rainfall decreases from 24 in. in the north to 16 in. at Ascalon (Ashkelon) and 10 in. near Beersheba. The Galilean hills receive up to 40 in. annually and Jerusalem 24 in. The Jordan valley is hotter and drier than the coastal region; the Dead sea has a rainfall of 2–4 in. The mild rainy season is from October to April with the maximum in December and January. Summers are dry and hot with midday temperatures of 29°–35° C. (85°–95° F.), but the coasts feel cooler with refreshing sea breezes. The Negev and Jordan valley have midday temperatures exceeding 38° C. (100° F.). On the coast mean midday maximums in winter vary between 15° and 18° C. (60°–65° F.), with minimum temperatures of between 7° and 10° C. (45°–50° F.). Occasional cold spells bring snow to the hills in most winters, but very rarely to the coast or Jordan valley. Hot spells in early summer are caused by dry winds (khamsin) from the Arabian desert or Sinai.

Vegetation.—The natural climax vegetation has largely vanished because of long cultivation and depredations of goats. The former oak forests of Sharon and Galilee are represented by isolated trees. Thin stands of Aleppo pine survive on Mt. Carmel, and there are some new forests of this tree in the Jerusalem corridor and near Nazareth. The hills are mainly covered with *maquis* and *garrigue* scrub. The coastal sand dunes and the Negev support only desert scrub. Most of the country north of Beersheba is under cultivation or hill grazing, and irrigated zones are green and fertile with citrus groves and fir, carob and eucalyptus plantations.

Animal Life.—Of the large wild animals once found in the country few survive; the most notable survivals are deer, wild boar, gazelle and ibex. Of the numerous species of birds the majority are migrants remaining for part of the year only. (C. G. Sm.)

History.—For the previous history, to the termination of the British mandate on May 14, 1948, *see* Palestine.

The New State.—Gen. Sir Alan Cunningham, the British high commissioner for Palestine, left the country on May 14, 1948, and on the same day the Jewish National council and the General Zionist council at Tel Aviv proclaimed the establishment of a Jewish state, to be called Israel, of which they would be the provisional government. David Ben-Gurion was appointed prime minister, and on May 16 Chaim Weizmann was elected president of the provisional council. The U.S. government immediately recognized the council as the *de facto* authority of the state, and *de jure* recognition by the U.S.S.R. followed on May 17. The five neighbouring Arab states—Egypt, Trans-Jordan (later renamed Hashemite Kingdom of Jordan), Iraq, Syria and Lebanon—announced that their armed forces would enter Palestine with the object of restoring order. The United Nations on May 20 appointed Count Folke Bernadotte af Wisborg as mediator, to bring about a settlement between Israel and the Arab states. The Arab forces occupied the areas in the south and east, which were not yet controlled by the Jews, and tried to blockade Jewish Jerusalem. The Arab legion of Trans-Jordan, despite a desperate defense by the Jews, obtained the surrender of the small Jewish quarter of the old (walled) city. The Jews, however, had won control of the section of the main road to Jerusalem in the Judaean hills and beat off all Arab attacks on their scattered settlements.

Count Bernadotte obtained a cease-fire of four weeks from June 11 and put forward proposals for settlement, which were rejected by both sides. The Arabs refused a prolongation of the cease-fire, and hostilities broke out again in July. The Jews gained lightning successes in nearly all sectors; they occupied Ramle and Lod, captured Nazareth and western Galilee (which had been allotted to the Arabs) and advanced their positions in the south. A second cease-fire was accepted on July 18. Count Bernadotte, assassinated in Jerusalem on Sept. 17 by Jewish terrorists, was succeeded as mediator by his deputy, Ralph Bunche of the UN secretariat. Despite the orders of the UN, the truce was not observed faithfully by either side, and by the early months of 1949 the Jews had occupied all the Negev up to the former Egypt-Palestine frontier, ex-

cept a strip of coast in the southwest corner between Gaza and Rafah, which remained in Egyptian possession.

The mediator secured separate armistice agreements between Israel and the Arab states (Egypt, Feb. 24, 1949; Lebanon, March 23; Trans-Jordan, April 3; Syria, July 20) and the Iraqi government withdrew its troops and transferred the areas occupied by them to Jordan. It was broadly agreed to fix a temporary frontier where the line had been at the beginning of the negotiations. Certain border areas were demilitarized, and the Jews secured adjustments in the western sector (so that the railway from Tel Aviv-Jaffa to Haifa was in their hands) and established a well-guarded corridor to Jerusalem. In Dec. 1948 the UN assembly appointed a three-member conciliation commission to promote a final settlement and to arrange an international regime for Jerusalem, but all its efforts were frustrated. By the armistice agreements, mixed commissions composed of Arabs and Jews, with a chairman from the UN staff, were established to deal with complaints of violation (*see* ARMISTICE). Israel was admitted to the UN on May 11, 1949.

Political Developments.—The provisional council of Israel organized elections in Jan. 1949 for a constituent assembly (*knesset*) of 120 members, elected by proportional representation, with the whole country treated as one constituency. Of the 12 parties represented, the largest were two wings of labour, divided on matters of foreign policy and the internal program: Mapai (Israel Workers), which won 46 seats, and Mapam (United Workers), more to the left, which won 19. The leader of Mapai, David Ben-Gurion, formed a coalition government with the Mapam, National Religious front and smaller centre parties.

The draft constitution was not discussed. It was decided to pass an interim organic law defining the legislative, executive and judicial powers and to let the constitution, insofar as it affected the rights of the individual, grow gradually. The *knesset* became a single-chamber parliament. The state was a republic. The president had the limited powers of a French president and appointed the prime minister after consultation with leaders of the parliamentary parties; the other members of the executive council (cabinet) were appointed on the prime minister's advice. The courts were independent of the executive and applied the law of mandated Palestine, which was largely English, subject to new legislation. Beside the civil courts, religious tribunals for Jews, Muslims and Christians had jurisdiction in personal status (which includes questions of marriage, alimony, divorce, succession and guardianship). Arabs had equal political rights and in 1956 and 1961 eight Arabs were members of the *knesset*. Nazareth, a predominantly Arab town, had an Arab municipality and an Arab magistrate.

Chaim Weizmann, the first president (elected in Feb. 1949), died in Nov. 1952. The second president was Isaac (Itzhak) Ben-Zvi (*q.v.*), a Mapai member of the *knesset* and a former president of the Jewish National council. He was re-elected for five years in 1957 and 1962. In the second assembly, elected in 1951, the General Zionists, a bourgeois party, gained seats at the expense of the extreme party of the left (Mapam) and of the right (Herut). The second coalition was largely composed of the same elements as the first, but after a year the General Zionists joined it. In Dec. 1953 Ben-Gurion retired into private life on a collective settlement in the Negev. Moshe Sharett, who was foreign minister, then took over the premiership in addition. Ben-Gurion returned as minister of defense in Feb. 1955, and after the third general election, held in July 1955, formed a coalition with four labour groups and the Progressives. In 1956 Sharett was forced to retire as foreign minister, and was replaced by Golda Meir (Myerson), then minister of labour. In the fourth general election, held in Nov. 1959, the position of Mapai, which had been the major party in every government, was strengthened, their representation being increased from 40 to 47 seats; Herut was the next strongest party with 17 seats. Ben-Gurion formed a coalition with Mapai as a nucleus and the same groupings as in the last cabinet. The government's program included regional disarmament and nonaggression pacts with Arab states, but nothing was accomplished.

The new coalition soon ran into trouble over an internal matter known as the "Lavon affair." The issue concerned the treatment of Pinhas Lavon, the secretary of the labour federation, who was forced to resign as minister of defense in Feb. 1955 for what was officially described as a "security mishap." The question of Lavon's responsibility was examined by a ministerial committee appointed by the cabinet and their report cleared him. Ben-Gurion, however, refused to accept the finding, which reflected on army officers, and demanded a judicial inquiry. He made cabinet acceptance of his view a matter of confidence and resigned, but was called back and Lavon was dismissed from his office. Ben-Gurion's action caused a rift in the Mapai party itself as well as with the other members. Ben-Gurion called for a general election in Aug. 1961, and the Mapai party lost five seats. Herut was again the second party with 17 seats, and a new Liberal party, compounded of the General Zionists and the Progressives, also had 17. The Communist party gained two places, which indicated the discontent of the Israeli Arabs. The new coalition was more limited than its predecessors and more dominated by Mapai.

Ben-Zvi died in April 1963 and was succeeded as president by his political associate, Schneor Zalman Shazar. A few months later Ben-Gurion resigned unexpectedly for personal reasons as premier and defense minister. He was succeeded by his minister of finance, Levi Eshkol, who promised to carry on the policies of his predecessor.

The principal enactments of the *knesset* in the early years included a Law of Return, which gave every Jew the right of immigration in accordance with the policy of "in-gathering the exiles"; education laws, which instituted free compulsory primary education for all children between 5 and 13 and a public-school system with two divisions, religious and secular; the National Service law (see *Defense*, below); and the Law of Nationality, which conferred Israeli citizenship on a wide basis.

The question of the international status of Jerusalem remained unsettled. From 1948 the city was divided into two completely separate sections, Jewish and Arab. Israel moved the *knesset* and most of the government offices (previously in Tel Aviv-Jaffa) to Jerusalem in Dec. 1949. The government declared itself willing to have the holy places put under the protection of a UN commissioner, but opposed international administration of the city. The kingdom of Jordan was equally opposed to an international regime. The UN, however, and many states did not accept the *de facto* position.

Relations With Arab States.—In 1950 the United States, Great Britain and France issued a tripartite declaration that they would maintain a balance of arms between Israel and the Arab states and would check any aggression whereby either side attempted to change the frontier fixed by the armistice agreements. From 1952 relations deteriorated, and frequent incidents on the Jordan and Syrian borders disturbed the peace, and were submitted by one side or the other to the Security council. Israel's plan to use the waters of the Jordan to irrigate the Negev by constructing a canal from Lake Hula provoked violent Syrian resistance, and the Soviet veto at the council prevented action. Attempts between 1953 and 1956 by Eric Johnston, the U.S. president's emissary, to get agreement on a comprehensive irrigation project for the use of the waters of Jordan and Yarmuk, for the benefit of Jordan, Israel and Syria, were frustrated by Arab intransigence.

The Sinai Campaign and After.—In 1955 the supply by the U.S.S.R. of jet aircraft and heavy armament to Egypt increased tension, and the efforts of the secretary-general of the UN in the spring of 1956 to obtain an unconditional cease-fire had only a very brief success. Raids by Arab commandos were resumed. After Col. Gamal Abd-al-Nasser's nationalization of the Suez canal in July, followed by parliamentary elections in Jordan which reflected his influence, and violent Arab threats of invasion, Israel mobilized its forces and on Oct. 29 invaded Sinai to destroy the hostile Arab bases there. In five days the Israeli army captured Gaza, Rafah, Al Arish and thousands of prisoners and occupied most of the peninsula east of the Suez canal.

To what extent, if at all, Israel was acting in collaboration with Great Britain and France in taking this action has not been established, although it appears that with the French government at least there was some understanding. A joint Anglo-French ultimatum was issued on Oct. 30 ordering Egypt and Israel to cease fight-

ing and withdraw ten miles from the Suez canal, failing which British and French forces would intervene. Further, Egypt was to allow British and French troops to occupy key points on the canal. (For the subsequent action taken by Great Britain, France and the UN *see* EGYPT; SUEZ CANAL; *see* also AVON, [ROBERT] ANTHONY EDEN, Earl of.)

As far as Israel was concerned the objects of the occupation of the Sinai peninsula, apart from the destruction of hostile bases, were to open sea communications in the Gulf of Aqaba and to put pressure on Egypt to negotiate peace. Under pressure of the UN Ben-Gurion stated on Nov. 8 that Israel would withdraw its forces from Egyptian territory when arrangements had been made for a UN emergency force to enter the area and replace British and French troops, which had seized part of the Suez canal.

Ben-Gurion delayed the withdrawal till he had assurance that the UN emergency force would be stationed within the borders of Egypt to prevent raiding from either side and to maintain free navigation in the Gulf of Aqaba. The emergency force of 4,500 men, under the command of Maj. Gen. E. L. M. Burns of Canada, took over its task in December. After further UN pressure the withdrawal of Israeli forces from Egyptian territory was completed in March 1957. For two years the frontiers were relatively quiet, but in 1959 tension again increased because of the seizure by Egypt of vessels in the Suez canal carrying cargo to and from Israel. There were also violent incidents along the northern borders. The blockade of the canal against Israeli shipping persisted. The UN continued their watch on Israel's borders.

By the early 1960s a remarkable feature in foreign relations was the development of economic and cultural links between Israel and the new states of Africa and the far east, with mutual agreements for technical help.

The country was stirred in 1960 by the abduction from Argentina of Adolf Eichmann by Israeli agents. Eichmann, who was taken as a notorious war criminal, a former head of the Jewish extermination department of the Nazi state secret police and principal instrument in the murder of 6,000,000 Jews, was brought to Israel to stand trial under an Israeli law of 1950. The trial opened in April 1961 before a special court of three judges and the court gave judgment in December, convicting him and sentencing him to death. An appeal was heard in March 1962 by the supreme court, which gave judgment on May 29 confirming the conviction and sentence. An appeal to the president for a reprieve was rejected and Eichmann was hanged on May 31.

Population.—After the state of Israel was created in 1948 the population increased considerably from an estimated 720,000 to well over 2,000,000 in the early 1960s, largely by means of immigration of Jews from Europe, Asia, Africa and America. Immigration during the period 1948–59 totaled well over 1,000,000. The first wave of immigrants came mainly from central and eastern Europe; the second from communities in oriental and Muslim countries (Yemen, Iraq, Egypt, north Africa). In 1959 oriental Jews comprised two-fifths of the Jewish population. These and Jews from many other countries have been greatly helped by the Jewish agency which was constituted in 1929 to promote Jewish settlement in Palestine. In the early phases of settlement many were placed in the homes and villages of the 700,000 Arabs who had fled during the Jewish-Arab fighting. The three main towns are the Israeli part of Jerusalem (the capital), Haifa and Tel Aviv-Jaffa (*qq.v.*).

The Arab community has small part in the socialist order of the state, except for the growth of co-operative societies in their villages. The Arab *fellahin*, who inhabited about 90 villages in the early 1960s, owned their land and enjoyed the social services of the government and equal civil and political rights, but they had a grievance as the majority remained under military administration for security reasons and required passes to move from one area to another. Arabic is the principal means of instruction in the Arab primary and secondary schools. An increasing number of Arab students are admitted to the Hebrew university and the Israel Institute of Technology.

The official languages are Hebrew and Arabic. The great majority of the Jewish population have acquired Hebrew. But newspapers are also published in Arabic, and in most of the European languages and Yiddish, which are the mother tongues of many immigrants. English is the principal foreign language, and is taught in primary schools from the age of nine through to university level. It is estimated that about 2,000 books are published in Hebrew annually. Besides Jews, there were in the early 1960s nearly 250,000 Arabs, of whom two-thirds were Muslims. The others were Druzes and members of different Christian communities. The ministry of religions assists the institutes of the various religious communities. The central shrine of the Baha'i world community, originally derived from Persia, is in Haifa. (For ethnical and cultural aspects *see* JEWS; JUDAISM; ZIONISM; HEBREW LANGUAGE; HEBREW LITERATURE; HEBREW RELIGION; JEWISH HOLIDAYS; JEWISH PHILOSOPHY; JEWISH ART.)

Administration and Social Conditions.—*Government and Constitution.*—Israel has no written constitution and follows the English tradition of letting constitutional law be formed pragmatically. Statutes lay down the functions of the cabinet, the ministers and the judiciary, the powers of the single-chamber parliament, the *knesset*, the system of election to the *knesset*, the right of all Jews to settle in Israel and receive immediate citizenship, and the principle of equal rights for women. The head of state is the president who is elected by a simple majority of the *knesset* in a secret ballot for a term of five years, and may be re-elected. The *knesset* (120 members) is elected by a system of universal adult suffrage and proportional representation. It sits for four years, but may be dissolved by statute during that period. The country is divided into administrative districts (*mehozot*) with subdistricts (*nafot; see* Table). There are three types of local government councils: municipal, local for larger villages and regional for agricultural areas. Each council can make bylaws, but these must be approved by the minister of the interior. It can also impose rates subject to the same approval. The councils are elected in the same way as the *knesset*, and hold office for four years.

The government, which is composed largely of representatives of the parties which created and control the labour organization, supplements the socialist structure. It has nationalized, in whole or part, the principal industries, electricity, the minerals of the Dead sea and the Negev, and chemical manufactures. It owns a great part of the land which belonged to the Arabs who fled in the war of independence. It shares ownership of rural land and of a portion of the urban property with the Jewish National fund (the pre-state instrument for acquiring land for agricultural settlements, housing quarters and public institutions). The nationalized land is leased to individuals or groups for a period not exceeding 49 years. The Jewish National fund is subscribed by the Jews of the

world, and is an element of the partnership between Israel and outside Jewry.

Political Parties.—The *knesset* has included from the beginning of independence about a dozen parties, and every government has been a coalition. The major party throughout has been Mapai (Mifleget Poalei Eretz Israel), the central labour group. Next in numbers is Herut, the extreme right wing. Others are the National Religious party, which is partly socialist; the bourgeois General Zionists; the labour group, Ahdut Avoda, which is activist and Socialist; Mapam (Mifleget Hapoalim Hameuchedet), the left-wing labour group; and the Aguda, the fundamentalist religious group. The Progressives, formerly a liberal wing of the General Zionists, decided in 1961 to combine with the latter as a new Liberal party. The Communist representation in the *knesset* was five, two being Arabs; and three Arab parties, linked with Mapai, had five members. The Mapam members included one Arab.

Living Conditions.—Living conditions in Israel are of an increasingly high standard, remarkable in view of the pressure of constant immigration. New immigrants have to be housed and fed and also trained for some form of occupation. Housing plans are based upon the formation of new towns and the settling of the rural areas. Unemployment during the decade 1950–60 continued to fall until it reached and maintained a level lower than that of the U.K. and U.S. During the same period consumer prices and earnings in manufacturing rose to an appreciable extent reflecting the increasing prosperity and growth of the economy.

Israel inherited from the Jewish community of mandated Palestine a system of voluntary socialism without any coercion of the state. During the mandate period a federation of labour (Histadrut) was formed, including the co-operative and collective agricultural settlements and the greater part of the industrial workers. It includes also the organs through which the economic life of the settlements is ordered, the marketing and distribution agencies for consumer goods, materials and equipment, a vast construction enterprise which builds settlements and public institutions, credit societies and banks, trade unions and co-operative groups of every branch of work. Altogether it counts nearly 750,000 members, including several thousand Arabs. The Histadrut conducts, also on a co-operative basis and often in partnership with private investors, major industrial and public enterprises; *e.g.*, irrigation, shipping and mining. Separate trade unions have been established for most vocations, but they form part of the over-all labour federation. Apart from those in the Histadrut, there are smaller unions composed of members of the parties which are opposed to labour.

The Histadrut is also responsible for a health service and a system of social insurance, which grew up under the mandate and has survived in the state. The government supplements it by old-age and widows' pensions, maternity benefits, workmen's compensation and some types of hospitals. The Histadrut engages in educational and cultural activity, maintaining secondary and technical schools, a widespread system of adult education for immigrants, drama companies, and the publication of books, newspapers and technical journals. It also deals with wage rates and working conditions in private industry.

Justice.—The law of Israel was declared, in the first legislation in 1948 by the provisional council, to be the law pertaining to Palestine in May 1948, so far as that is not in conflict with any law passed by the Israeli legislature. The Palestine law was derived from three sources: Ottoman, English (common law and equity) and the ordinances of the Palestine legislature.

There are both civil and religious courts. The principal civil courts are: (1) magistrates courts, which have minor civil and criminal jurisdiction; (2) district courts in Jerusalem, Tel Aviv and Haifa, which deal with major civil and criminal cases; (3) the supreme court, sitting in Jerusalem, which hears appeals in civil and criminal cases from the district courts, and has jurisdiction in first instance in administrative matters touching the liberty of the subject and powers of officials. The religious courts have jurisdiction in matters of personal status, which differs with the communities. The Jewish Rabbinical courts have exclusive jurisdiction in matters of marriage and divorce, and concurrent jurisdiction with the civil courts in other matters of personal status, both for Israeli and foreign Jews who consent to the jurisdiction. The Muslim Shariah courts have exclusive jurisdiction in all matters of personal status of Muslims, including foreign subjects where their national law recognizes religious tribunals. Separate religious courts are established by the Christian communities, and have jurisdiction similar to that of the rabbinical courts. Where actions of personal status involve persons of different religious communities, the supreme court decides which tribunal has jurisdiction. Military courts have been invested with wide powers.

Education and Culture.—By the early 1960s about 500,000 children, including 50,000 Arabs, were in primary, secondary or technical schools. Primary education is free; secondary schools, in which fees are paid, are maintained by municipalities and voluntary bodies with government aid. There are five institutes of higher education: the Hebrew university at Jerusalem (founded 1918, inaugurated 1925), the religious Bar-Ilan university (1953) at Ramat Gan near Tel Aviv, the Israel Institute of Technology (Technion, founded 1912, inaugurated 1924) at Haifa, the Weizmann Institute of Science for basic and applied research (1949) at Rehovot and Tel Aviv university. The Hebrew university has six faculties: humanities, science and mathematics, medicine, law, agriculture and the social sciences. The Institute of Technology, which also gives degrees, has faculties of engineering and architecture. In the religious schools special attention is given to the teaching of traditional and rabbinical literature. But in all schools (apart from Arab state schools) the Hebrew Bible is the literary and historical foundation, and the Bible quiz is the most popular entertainment in the country. Biblical archaeology and geography are universally learned and for immigrants they provide a valuable link with the country and the feeling of having roots.

Defense.—The National Service law, 1950, as amended, introduced compulsory service for 2½ years for males between 18 and 26 years, and 2 years for those between 27 and 29 years. Unmarried women between 18 and 26 do 2 years service. For both men and women the service includes work on the land. Men up to the age of 49 and childless women up to 34 do service in the reserve. The war strength of the army is about 250,000. Israel's navy includes a few destroyers, frigates, submarines and motor torpedo boats. There is a naval officers' school at Acre. The air force has 12,000 men and about 400 aircraft, including French jet and supersonic fighters. Training planes are built in Israel under licence of the French.

The Economy.—Israel in 1948 was a country poor in agriculture, natural resources and industry. Its economy was beset by serious problems. For the maintenance of the population and its mass of immigrants the state had to import foodstuffs, consumer goods and raw materials. Because of the hostility of the neighbouring Arab states, a considerable portion of the national budget continues to be required for defense. The economy, based on a mixture of private and state enterprises with much financial assistance from the Jewish communities of the world, is heavily dependent on investment from abroad. However, a broad economic growth has been achieved and productivity is high.

Agriculture.—By the 1960s Israeli agriculture using modern techniques and irrigation methods supplies three-quarters of the home food supply. The export of citrus fruit, Israel's most valuable crop, was much increased and the cultivation of peanuts (groundnuts), sugar beets and cotton expanded. The proportion of the population living in rural areas rose from 15% to 20%; and of 800 Jewish agricultural villages, mostly collectives and co-operatives, the majority were founded after the creation of the state; more than 100 are in the Negev, which was before mainly arid and empty.

Industry and Mining.—Industrial expansion has been remarkable and provides employment for more than 160,000, excluding those engaged in building. Diamond cutting and polishing, the manufacture of textiles, chemicals, paper, tires and electrical goods, and light industries of many kinds are fostered.

The mineral wealth of the Dead sea (potash, magnesium and bromide) and of the Negev (copper and phosphates) is exploited.

Oil and natural gas have been struck several places in the northern Negev, and together supply one-fifth of Israel's needs. An oil pipeline was laid from Elath (Eilat) on the Gulf of Aqaba to the Mediterranean coast. Electricity, generated by thermal stations, is the main source of power for industry and irrigation.

Israel became the seventh nation to launch a rocket into the ionosphere when the Shavit (Meteor) 2, designed for meteorological research, was successfully fired on July 5, 1961. An atomic reactor has been constructed with U.S. assistance near Tel Aviv and a second reactor in the Negev with French help.

Trade and Finance.—The main imports are machinery, iron and steel products, rough diamonds, cereals and crude oil. Besides citrus fruit the principal exports are eggs, polished diamonds, textiles, chemicals, motor vehicles (assembled in Israel) and tires. While in 1949 the ratio of the value of imports to exports was 5:1, by the early 1960s it was 2:1. The chief trading partners are the U.S. and the U.K. Half of the citrus export goes to the U.K.

The adverse balance of trade, which in the early 1960s still exceeded $300,000,000 annually, was met by four sources: (1) reparations in kind paid by West Germany to Israel for ten years from 1953 ($80,000,000 a year) and compensation paid to individuals in Israel for property stolen and sufferings inflicted by the Nazis (about $30,000,000 a year); (2) the contribution of Jewish communities in all countries where they are free; (3) independence and development loans floated by the government of Israel in America and loans from foreign banks; (4) an American grant-in-aid and United Nations technical aid. While a large part of the investment capital comes from government and public bodies, private investment is encouraged by tax and customs concessions. The government since 1952 has balanced its working budget, including the heavy defense expenditure, which takes one-third of the revenue. Income tax, customs and excise, land and luxury taxes are the main sources of revenue; tourism is a factor of growing importance. The development budget is provided largely by foreign contributions.

Currency and Banking.—The Israel pound (IL.), divided into 1,000 *prutoth* and 100 *aguroth*, was originally equivalent to £1 sterling. The inevitable inflation brought a steep decline in the exchange rate, and in 1953 the government carried through a devaluation, fixing the rate at IL.5 to £1, or IL.1.80 to $1. Renewed inflation, due largely to armament expenditure, caused another decline in the free market and varying rates of exchange for different transactions until 1962, when the Israel pound was further devalued to IL.3 to U.S. $1 and IL.8.40 to £1. The cost-of-living index continued to rise, though after 1956 more gradually.

In 1954 the Bank of Israel was created; it issues notes and is the sole banker of the government. The other principal banks are the Bank Leumi (which has replaced the Anglo-Palestine bank), the Discount, Workers' and Barclays banks.

Transport and Communications.—The state-owned railways extend over 392 mi. and hard roads over 1,864 mi.

The merchant marine has been developed, and by the early 1960s had a tonnage of more than 600,000. The ships are built mostly in West Germany. In addition to the ports of Haifa and Tel Aviv-Jaffa, a harbour has been built at Elath with access to the Red sea and the Indian ocean. Air communications are centred at Lod international airport near Tel Aviv. Kol Israel (the Voice of Israel) is the national broadcasting station with studios in Jerusalem, Tel Aviv and Haifa.

ISRAELI, ISAAC BEN SOLOMON (*c.* 850–950), Jewish physician and philosopher, was born in Egypt and became court physician at Kairouan (Kairwan). His medical works were translated by Constantine the African (1087) and include a *Book on the Fevers* much esteemed in the middle ages. His extant philosophical writings are: a *Book of Definitions and Descriptions* (Hebrew trans. by Nisim ben Solomon; Latin version by Gerard of Cremona, edited by J. T. Muckle in *Archives d'histoire doctrinale et littéraire du moyen âge*, vol. xii–xiii, 1938), mainly based on al-Kindi; a *Book on the Elements* (Hebrew trans. by Abraham ha-Levi bar Hisdai; Latin version by Gerard of Cremona); a *Treatise on Spirit and Soul*, probably part of an exegetical work in which Israeli sought to adduce scriptural support for his philosophical doctrines; the *Book of Substances;* and a treatise designated in Hebrew as *Chapter on the Elements*. The latter two works (edited by S. M. Stern and by A. Altmann, *Journal of Jewish Studies*, vol. vii, no. 1–2, 1956) are based on a pseudo-Aristotelian source otherwise lost which offers an important variant of Neoplatonism. Israeli's doctrine had a pronounced influence on the 13th-century Jewish mystics in Gerona. Ibn Gabirol too seems to be indebted to it.

For medical and philosophical treatises extant in Latin see *Opera omnia Isaci* (1515). *See* also J. Guttmann, *Die philosophischen Lehren des Isaak ben Salomon Israeli* (1911). (A. AN.)

ISRAELI LAW. In ancient times, when the people of Israel lived in their homeland, they created their own law: the law of the Torah (*see* PENTATEUCH) and—as a historical development of the Torah—the law of the Mishnah and the Talmud (*q.v.*). Then came the separation of land and people for more than 1,800 years. The law left the land together with those who had created it and the land acquired other laws, changing from time to time with the change of consecutive conquerors. The Jews took their law with them wherever they went, continued to develop it and submitted to it wherever their communities enjoyed any measure of autonomy. It had been one of their national, cultural treasures and remained so during the centuries of the Diaspora. Therefore, when the Jews eventually returned to their ancient land in the 20th century, they brought back with them a dual legal heritage: that of the historic Jewish law and that of the laws of the countries in which they had been living.

Before Independence.—Until the end of World War I, Palestine was ruled by the laws of the Ottoman empire. Some of these were derived from Muslim religious sources; others were based on Turkish customary rules; many had been taken over from European, mainly French, legislation. In matters of personal status (marriage, divorce, maintenance, guardianship, succession, etc.), the Ottoman empire permitted religious courts to exercise jurisdiction and to apply their religious law.

During the 30 years of British administration (from 1922 to 1948 under the mandate for Palestine of the League of Nations), the law of the country became much anglicized. Large and important parts of Ottoman law were gradually replaced by legislation based on English law, including the whole of commercial law, criminal procedure and the law of torts. A provision of the Palestine order-in-council of 1922 enjoined the civil courts to apply "the principles of common law and the rules of equity prevailing in England" wherever Ottoman or mandatory legislation would "not extend or apply." Under this rule modern English rules of contract were added to the Mejellah, the Ottoman-Muslim code of civil law; equitable doctrines of ownership and specific performance became coupled with forms of Ottoman land tenure. Prerogative writs with their judicial protection of civil rights and liberties—unknown in the Ottoman system—were also introduced and firmly established.

Under the terms of the mandate for Palestine, the Jewish agency was recognized as an official representative body with certain functions of public law but without the right to take part in legislating. On the other hand, in their voluntary organiza-

tions, the Palestinian Jews developed certain legal institutions which were to have a considerable impact on the future Israeli law. Equality of men and women in family, work, defense and political life; a general tendency toward the structure and activities of a modern welfare state; the peculiar land tenure of the Jewish National fund, the national land-holding corporation—these are among the basic features which were firmly, though not statutorily, established well before the state of Israel came into existence.

After Independence.—When independence was proclaimed in 1948, the law which had been in force in Palestine at the end of the mandate was declared to remain in force in the new state "subject to such modifications as may result from the establishment of the state and its authorities," and some of the Ottoman enactments and much law of English origin continued to be applied. English ceased to be the predominant legal language and was immediately replaced by Hebrew. The law was henceforth made by the democratic authorities of the autonomous state which, in spite of an Arab minority of nearly 10%, is Jewish in conception, way of thinking and purpose. Yet, as a legal system, Israeli law is a mixture of various, frequently contradictory elements among which original Israeli law covers a relatively small, though important, part of the field.

Institutions and Offices.—The first and principal task of lawmaking was concerned with the new authorities of the state. A one-chamber parliament of 120 members, called the *knesset*, was set up and its constitution defined. General, direct, equal and proportional elections, to be held every four years, were regulated. There was created the office of president of the state, elected by the *knesset* for five years with mainly representative functions. The government, to be formed on the initiative of the president of the state by one of the *knesset* members, was declared to be responsible to the *knesset* and to depend on its confidence. The office of state comptroller, with broad supervisory tasks, was also established and a national bank, the Bank of Israel, set up.

Immigration and Citizenship.—New, and fundamental, also was the approach to immigration and citizenship. Instead of the heavy restrictions on Jewish immigration into Palestine which had been one of the main policies of the mandatory administration during its last years and the foremost issue on which the Jewish population had fought for independence, it was now proclaimed, by the Law of Return of 1950, that "every Jew shall have the right to come to Israel as a permanent settler." And under the Nationality law of 1952 every Jew who came to the country permanently, or was born in it, became an Israeli citizen.

In immigration and automatic acquisition of citizenship Jews are constitutionally privileged in Israel. In all other respects there is no distinction between Jewish, Arab and other non-Jewish inhabitants of the country. This is true of the right to vote and to be elected to the *knesset* or the municipalities; acquisition of property, including immovable property; the right to work and other civil liberties and their protection; education; social services, etc. Certain restrictions on free movement in certain parts of the country are emergency measures of security, maintained because of the state of armistice, not of peace, between Israel and the surrounding Arab states.

Courts.—The organization and jurisdiction of the courts, both civil and religious, and the appointment and tenure of judges also were the object of legislation, but the previous system was, on the whole, maintained. Courts are composed of professional judges only, the jury being unknown. Civil courts are organized on three levels: magistrates courts dealing with certain civil matters and offenses punishable with imprisonment up to three years; district courts in the three principal cities, with general jurisdiction in civil and criminal matters; and the supreme court in Jerusalem, deciding appeals from inferior courts and exercising, as court of first and only instance, jurisdiction as high court of justice. There is no appeal from a judgment of the supreme court, but it may allow a case to be reheard before itself with an increased number of judges.

Religious courts continue to be competent in matters of personal status, with some minor changes in the scope of jurisdiction of the rabbinical courts. In certain cases, mainly in suits concerning marriage or divorce, the jurisdiction of these courts is exclusive; in others it is concurrent with that of the civil courts and depends on the submission of the parties concerned. In matters of social security and in various other administrative matters, committees, all of them headed by judges, act as administrative tribunals whose decisions are subject to review by the supreme court.

Civil and religious judges are chosen by committees composed of members of the highest tribunal, members of the government, members of the *knesset* and members of the bar association. Formal appointment, which is for life, is by the president of the state.

Constitutional Law.—Israel has no formal constitution, mainly because of a reluctance to take permanent decisions on basic issues at a period when the prime purpose of the state is the ingathering of its prospective inhabitants and their integration into a homogeneous nation. Constitutional matters are, accordingly, regulated by ordinary legislation which may, with very few exceptions, be freely amended at any time by a simple majority of the *knesset*. The system is, in this respect, comparable to that prevailing in England and appears to work satisfactorily.

In another aspect of constitutional law, the lawmaking function of the high court of justice was of outstanding importance, for the body of decisions of that court defined and safeguarded the human rights and civil liberties of the citizen. A law enjoining statutory authorities to state their reasons whenever they refuse an application for the exercise of their powers helped the courts and administrative tribunals better to perform this task.

Other Developments.—In administrative law, legislation covers most subjects with which the legislature of a modern welfare state is concerned, including education, compulsory military service (for men and women) and national insurance. Particularly important for the economy of the country are the Water law and the law on the Encouragement of Capital Investments, both of 1959. Laws dealing with collective bargaining, labour exchanges, protection of wages, safety regulations, etc., are the nucleus of a code of labour law.

With regard to civil and commercial law, criminal law, procedure and evidence, the *knesset* confined itself to piecemeal amendments of the previously existing law. Among the outstanding departures from the Ottoman-English heritage are: the abolition of the death penalty for murder and the introduction of suspended prison sentences; a new way of taking evidence of minors in trials of sexual offenses; an amended and reduced form of preliminary inquiry in felonies; liability of the state in torts and the application to the state of various enactments from which it had been exempted; legal recognition and regulation of the payment of key money; the tenure of co-operative houses with separate ownership of flats; a law fixing the minimum marriage age of girls at 17; a law on the duties of maintenance between relatives; and a law on women's equal rights. The last-mentioned law contains only a few, general provisions. Details and the ensuing legal organization of the family are left to the determination of the courts. They must be treated by comprehensive legislation of which drafts were prepared and published; by 1961 only portions, such as the Maintenance law, had been enacted.

Jewish law as such continued to be applied by the rabbinical courts within their jurisdiction in matters of personal status; it is applied also by the civil courts when called upon to deal with such matters concerning Jews. In other fields of law it is not applied as the law of the land; nor was it given secular force by restatement of its rules in any of the enactments of the *knesset*. It serves, however, as an important source for the shaping of new rules of law, both by the *knesset* and in the creative decisions of the courts. At the same time, modern laws of various other nations are consulted and used for comparison, and decisions of foreign tribunals, not necessarily of English courts, are frequently cited as persuasive authorities. *See* also ISRAEL: *History; Administration and Social Conditions.*

ISRAËLS, JOZEF (1824–1911), Dutch painter and etcher, leader of The Hague school of peasant genre painting which flourished in the Netherlands during 1870–90, was born at Groningen of Jewish parents on Jan. 27, 1824. He began his studies in Amsterdam, but admiration for Ary Scheffer led him to Paris (1845–47), where he worked under F. E. Picot, Horace Vernet and H. Delaroche. He first tried to establish himself as a painter of portraits and of conventional history pictures, but had achieved little success when in 1855 ill-health compelled him to quit Amsterdam for the fishing village of Zandvoort, near Haarlem. The change of residence revolutionized Israëls' art and henceforward he became the painter of Dutch fisherfolk and peasants. In 1871 he moved to The Hague, often working in nearby Scheveningen. He died at The Hague on Aug. 12, 1911. Israëls' style was one of sentimental naturalism and he preferred pathetic themes, like "The Shipwrecked Mariner" (1861, National gallery, London). (A. Bs.)

ISSACHAR, in the Old Testament, Jacob's ninth son, his fifth by Leah (Gen. xxx, 18), is the eponymous ancestor of one of the northern tribes of Israel. Issachar played an insignificant part in Israelite history, and the name hardly occurs in later times. *See* TWELVE TRIBES OF ISRAEL.

ISSERLES, MOSES BEN ISRAEL (*c.* 1525–1572), known as the ReMA, who played an important part in codifying Jewish law, was born in Cracow, Pol., and was head of the great *yeshiva* founded there by his father. Most of the codes had been written by Spanish Jews (those of Isaac Alfasi, Maimonides and Jacob ben Asher being the best known and most authoritative), and though they were studied all over the Jewish world, they had become progressively less acceptable north of the Alps. This was due to the fact that the many customs (*minhagim*) that had been developed in the Rhineland and the east by the Germano-Polish (Ashkenazic) Jews were largely ignored by the Spanish (Sephardic) codifiers. Jacob ben Asher's code (*Arb a'ah Turim*, or *Tur*) had been commented on by the Spanish Joseph Qaro, taking little note of Ashkenazic customs. To remedy this, Isserles wrote his own commentary to the *Tur*, "The Paths of Moses" (*Darkhe Moshe*), in which he based many decisions on Ashkenazic customs. Subsequently Qaro published, for popular use, his own code, *Shulhan 'Arukh* ("The Well-Laid Table"; 1555), which was greeted with strong opposition from the Germano-Polish scholars. It was Isserles' commentary to this code, called the *Mapo* ("The Tablecloth"), utilizing Ashkenazic customs, that made the *Shulhan 'Arukh* acceptable all over the Jewish world and, since that time, the final source of decision for Orthodox Jewry.

Isserles was also interested in philosophic and cabalistic studies, considering both these disciplines to be varying expressions of the same religious truth. His chief works, in addition to the commentaries on the *Tur* and the *Shulhan 'Arukh*, are numerous *responsa* (legal opinions, collected after his death), *Toras Chatas* ("Law of the Sin-Offering," on ritual law), and *Toras ha'Olah* ("Law of the Burnt-Offering," a philosophic symbology of the ritual in the Temple at Jerusalem). He died at Cracow on May 1, 1572.

Isserles was greatly revered, and the phrase on his tombstone was frequently used in reference to him (as it had been to Maimonides and later was to Moses Mendelssohn): "From Moses [Maimonides] to Moses [Isserles] there was none like unto Moses." (S. B. FR.)

ISSUS, BATTLE OF. The battle of Issus was fought in Nov. 333 B.C., on the coast of the modern Gulf of Iskenderun, Turk., between the armies of Alexander the Great of Macedonia and Darius III of Persia. For a general account of the invasion and the composition of the Macedonian army *see* ALEXANDER III.

Hearing that Darius' army was east of the Amanus (Nur Daglari) range, Alexander left his sick at Issus at the head of the gulf and moved southward along the coast, but at Myriandrus (near Iskenderun) he heard that Darius had turned northward, crossed the Amanus by the northernmost pass and come down to Issus and was now in his rear. The army returned hastily northward to meet Darius' army, which had reached the Pinarus (either Payas or Deli) river.
